Professor Paul F. Mundé, in discussing my paper on Uterine Displacements, stated that he "had for many years advised the introduction of a pessary as a cure for an old retrodisplacement of the uterus before a parturient woman, so afflicted, was allowed to leave her bed, at the time when all her pelvic organs were undergoing involution."

The writer would tampon in these cases, even with the pessary in position, and add the iron, ergot, digitalis, or massage, when indicated.

In closing, this society is urged to aid in the attempt to destroy absolutely the reliance heretofore placed in post-partum cases upon that discredited old individual, Dame Nature.

66 WEST FIFTIETH STREET.

Therapeutical Notes.

Vaginal Suppositories of Quinine in the Treatment of Leucorrhœa.—Hardwicke (*Lancet*, January 7th) reports good results from the insertion once a day of a suppository containing three grains of quinine hydrobromide.

Suppositories for Cystitis.—The *Gazzetta degli ospedali e delle cliniche* for January 31st attributes the following suppository to subdue the pain of cystitis to Guyon:

B Extract of belladonna, $\frac{1}{2}$ of each..	15 grains;
Extract of opium,	15 "
Iodoform	3 grain;
Virgin wax	15 grains;
Cocoa butter	45 "

M.

To make one suppository.

Urtica Dioica as a Hæmostatic.—Both (*Archiv der Pharmacie*, xliii; *Journal de médecine de Paris*, January 29th) recommends a tincture of the stems, leaves, and flowers of the stinging nettle (*Urtica dioica*), gathered in the spring, as an application to hæmorrhagic surfaces in cases in which there is no lesion of a large blood-vessel.

Iodine in the Treatment of Chronic Eczema of the Hands.—The *Revista de Medicina y Cirugía Practica* for January 15th, quoting the *Therapeutische Monatshefte*, attributes the following formula to Edlén:

B Iodine	13 grain;
Potassium iodide	4 grains;
Glycerin	180 "

M. To be applied every night, and the hands covered with compresses.

THE NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 11, 1899.

SUTURE OF THE HEART FOR PENETRATING WOUNDS.

IN the *Giornale internazionale delle scienze mediche* for January 15th there is published a communication that was presented before the Royal Medico-chirurgical Academy of Naples on August 14, 1898, by Professor Giovanni Ninni, who, combining the statistics of Jamin, Latelenet, and Fischer, finds that in only nineteen per cent. of the cases of penetrating wound of the heart does immediate death take place, so that in the great majority of instances surgical intervention may be resorted to in the well-grounded hope of saving life, provided no time is lost. He mentions eight cases treated by means of suture, and gives the details concerning one of them, which occurred in his own practice.

In Farina's case the wound, which was at the apex and edge of the right ventricle, was seven millimetres (about a quarter of an inch) long. It was sutured immediately. The patient died on the sixth day, probably of pneumonia. In Rehn's case the wound, which was fifteen millimetres (about half an inch) long, was in the same situation. It was not until twenty-four hours had elapsed, and the patient appeared moribund, that suture was performed, with partial suture of the pericardium, and drainage of the pericardium and pleura established. The patient recovered. In Cappelen's case the wound was at the apex and edge of the left ventricle, and was two centimetres (about three quarters of an inch) long. The left coronary artery was wounded. Intervention was resorted to within a few hours. Primary union took place, but the patient died of pericarditis on the second day. In Parozzani's first case the wound was of the same size and situation as in Cappelen's. Suture was resorted to at the end of twelve hours. Primary union occurred, and the patient recovered. In Parozzani's second case the wound was the same in situation, but only fifteen millimetres (about half an inch) long. The operation was performed within a few hours. There was primary union, but the patient died in collapse on the second day. In the author's own case the wound, which was twenty-five millimetres (about an inch) long, involved the anterior wall of the left ventricle a little beneath the transverse sulcus and a little to the outer side of the longi-

tudinal sulcus, and ran parallel with the long axis of the heart. Surgical intervention was almost immediate, but the patient died before the flap of the thoracic wall had been entirely sutured. In Giordano's case the wound was of the edge of the left ventricle and was two centimetres (about three quarters of an inch) long. After two hours the heart and pericardium were sutured, and drainage of the pleura was established. Death took place on the twentieth day, from septic pleurisy of the left side with multiple pulmonary abscesses on the right side. In Parlavocchio's case the wound was V-shaped. The two arms of the V measured together about three centimetres and a half (approximately, an inch and a quarter). After eight hours it was sutured, primary union took place, and the patient recovered. Concerning Rudis-Jicinsky's case (*New York Medical Journal*, April 23, 1898), Ninni does not consider it certain that the wound was penetrating. Dr. Rudis-Jicinsky did not state that it was.

The author mentions these cases in the order of their occurrence. The first one, Farina's, occurred in June, 1896. The results, three recoveries in eight cases, may, we think, be held not only as warranting surgical intervention, but as rendering it imperative under ordinary circumstances; as the author himself puts it, "Systematic abstention has no *raison d'être* in penetrating wounds of the heart."

PROFESSOR VIRCHOW ON INNOVATIONS IN ORTHOGRAPHY, ETC.

IN the first number of volume cly of the *Archiv für pathologische Anatomie und Physiologie und für klinische Medizin* the venerable editor of that great journal gives the reasons why in its pages he has not fallen in with the new-fangled notions of the pedagogues (*Schulmonarchen*) as to the spelling of certain classes of German words, and intimates that he is not likely to adopt their innovations. He deals with the virtual suppression of the letter *c*, save in certain proper names or when followed by *h*, and its supersession by *k* and *z*; with the substitution of *t* for *th* and the dropping of the terminal *h* in some words such as *roh* (humorously declaring it a *Roh-heit* to write "*Rohheit*"); and with the replacement of the infinitive termination *-iren* by *-ieren*. He does not deal with the change of the terminal *-ss* to *-s*, but the words *Bedürfniss* and *Verständniss* occur several times in his article, and in only one instance, presumably by a typographical error, is the final *s* omitted. We notice, too, that the *Archiv* still employs *Ac*, *Oe*, and *Ue* instead of *Ä*, *Ö*, and *Ü*.

We are glad to see that Professor Virchow takes this stand, because his doing so can hardly fail to prove a powerful aid to the reaction that has already set in in Germany against the mandates of the "*Schulmonarchen*." We have not space to give the arguments that he employs, but we can assure our readers that they are full of his customary cogency. The German language is not the only one that is suffering at the hands of the professed *Weltbesserer*, and whenever a man of Virchow's power lifts a hand in rescue of its purity the task of opposing the poacher in the field of English is lightened.

Incidentally, Professor Virchow remarks upon some technical terms in use in medical writings—for example, the application of the term *sterno-cleido-mastoid* to a muscle which of course is not nipple-shaped; that of *arachnoid* to blood-vessels that are in no wise suggestive of a spider's web; and the substitution of *deltoideus* for *deltoides* as a name for the deltoid muscle. We fancy we detect a shade of deserved derision in his remark on the common use of *ary-* for *arytano-*, and his humor is unrepressed when he comes to speak of the interminable words coined by the chemists—"Tape-worm words" (*Bandwürmer von Worten*), as he calls them. He still thinks it best to assist the reader's understanding by breaking these words with an occasional mile-post in the shape of a hyphen.

MINOR PARAGRAPHS.

THE ARCHIVES OF NEUROLOGY AND PSYCHOPATHOLOGY.

WE can not refrain from calling attention to the exquisite appearance of this new publication. The third number of the first volume, issued from the State Hospitals Press, in Utica, in February, has, we believe, never been excelled, the world over, by any medical periodical, as regards typography and press work. And the material presented, consisting of two hundred pages of reading matter, is worthy of its sumptuous dress. It embraces an article entitled *Studies on Ganglion Cells*, by Dr. James Ewing, and one entitled *Bibliographical Contribution to the Cytology of the Nerve Cell*, by Dr. Smith Ely Jelliffe. Dr. Ewing's article is illustrated by means of six beautifully executed plates, by the Helio-type Printing Company, of Boston, which are reproductions of the author's own drawings, many of them in colors. The number is worthy of being bound by itself as a monograph.

THE ANOMALIES OF ENGLISH MEDICAL DEGREES.

THE *Journal of the American Medical Association* for March 4th, in an editorial on this subject, falls into a few errors of fact, which is not at all surprising. They do not, however, invalidate in any way the purport of the journal's argument. The first error is the statement that the three colleges of surgeons of England, Scot-

land, and Ireland respectively grant only the two diplomas of membership and fellowship. Now, as a matter of fact the College of Surgeons of England has no licentiates, but only members and fellows; while those of Scotland and Ireland have no members, but only licentiates and fellows. It is hardly correct to say that "there is no surgical equivalent for the awful dignity of an F. R. C. P." The highest grade, viz., F. R. C. S., of the various colleges of surgeons does correspond to the grade of F. R. C. P., but the English College of Surgeons has no equivalent for the lowest grade of L. R. C. P., while the Scotch and Irish colleges have no equivalent for the intermediate grade of M. R. C. P. It is true that the English M. R. C. S. has no voice in the government of his college, and that practically his qualification is only a license. Again, there are many universities besides Oxford, Cambridge, London, Durham, Edinburgh, and Dublin which are authorized to grant the various medical degrees, viz., Aberdeen, St. Andrew's, and Glasgow—all ancient and historical universities in Scotland—and two recent ones, the Royal University in Ireland, and the Victoria University, Manchester, in England. To these we believe the University of Birmingham has been recently added. There is no doubt, however, that the increasing dissatisfaction with the cumbersome system of medical graduation in England will eventuate before long in some very radical changes. The essential distinction between the M. D. and the various qualifications lies in the fact that from an academic or university point of view a doctorate, whether in medicine, law, theology, or what not, is regarded as a purely scholastic distinction, and only incidentally and in later times connected with the pursuit of any professional vocation. But, as a matter of fact, current practice has departed for so long from the academic standpoint that sooner or later the latter must accommodate itself to the former. We may, perhaps, be permitted to say that in our opinion the decadence of pure scholasticism is a misfortune; at the same time we can not shut our eyes to it as a fact.

A CASE OF CURE OF PROGRESSIVE MUSCULAR ATROPHY.

AN interesting case is recorded by Dr. A. H. P. Leuf, of Philadelphia, in the *Pennsylvania Medical Journal* for February. It is that of a typesetter, twenty-four years of age, who was first seen on July 12, 1895, and found to be suffering from the symptoms of progressive muscular atrophy. The case was also diagnosed as one of progressive muscular atrophy at the department of nervous diseases of Jefferson Medical College. The chief value of the report is the careful record of the electrical reactions tending to place the accuracy of the diagnosis beyond doubt—a matter of great importance—since the patient was on February 6, 1899, nearly six years later, apparently completely cured. The author says that the patient's symptoms in no way indicated the diseases with which progressive muscular atrophy might be confounded—namely, chronic myelitis of the anterior horns, peripheral neuritis, syringomyelitis, atrophic joint affections, amyotrophic lateral sclerosis, and muscular pseudo-hypertrophy. The treatment consisted of the constant current administered three times weekly for five minutes to each hand—the strength, in the absence of a milliampèrèmeter, being stated as twenty cells of a liquid chloride-of-silver battery. At first strychnine sulphate, one thirtieth of a grain, with ar-

senic, one one-hundred-and-twentieth of a grain, and gentian, was administered three times daily. This was discontinued on August 27th, and reliance placed solely on galvanism, reduced to fifteen cells, and massage—continued up to November, 1894. Cures in this disease are so rare as to be well deserving of special record.

CAMPHOR AS AN ANTIDOTE TO CARBOLIC ACID.

ALTAREZ (*Revue de thérapeutique*, January; *Giornale internazionale delle scienze mediche*, January 31st) relates a case of carbolic-acid poisoning to which he was called in consultation. He thought that the poison had all been absorbed, and so he did not try to provoke vomiting, but advised camphorated oil to the amount of about three ounces, simply for the sake of its soothing action on the gastric and œsophageal lesions probably caused by the acid. But it seems to have accomplished more than this, for the patient recovered.

MEDICAL MEN AND THE LAY PRESS.

THE increasing frequency of reports of surgical operations, etc., in the lay press is a source of considerable disquietude to the more honorably minded members of the medical profession. As a rule, however, such reports are made ostensibly by a lay reporter; and, while it is unlikely in most instances that he obtained his information without the connivance of those concerned, we are always anxious to give the benefit of the doubt as to any ulterior or unworthy motives being at work. When, however, as related in *The Progress of Medicine* for February 15th, a San Francisco physician, a teacher in a medical school, writes in the first person for the *San Francisco Examiner* for February 6th an article entitled *How I Removed Patrie's Stomach*, it sets us wondering how long any vestige of gentlemanly instinct will remain as a characteristic of the practitioners of the "learned" profession of medicine.

THE NORTH DAKOTA MARRIAGE BILL.

WE have already expressed our opinion upon undue restrictive legislation so strongly that it seems almost unnecessary to add anything more on this subject. The end sought to be attained, viz., the prevention of the perpetuation of unhealthy strains, whether physical or mental, is undoubtedly admirable, and has our entire sympathy. But we do not think that legislation which regards the love union of two people in the light merely of a stud-farm arrangement would be a proper way to effect that result, even if it were practicable. Moreover, we believe that since individual human sentiment always has been, is, and in our opinion will be stronger than any other consideration, we do not think that there is the remotest possibility of such legislation even aiding in the accomplishment of its purpose; while we are quite sure that it will be responsible for a great increase not only of "illicit" but also of promiscuous intercourse. In our judgment, the proper course is the education of public sentiment by the instruction of the youth of both sexes in the ethics of adolescence, and particularly in the relation of sexual matters to love.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

MR. TAYLOR's special articles on this subject, which have now been running in the *Journal* for a number of weeks, have elicited much commendation from our read-

ers. They treat of matters any one of which may at some moment become of great importance to the practitioner, and, yet, they are matters concerning which the profession has little if any systematized information. These articles will be continued until the whole subject has been covered.

MACHETE WOUNDS IN CUBA.

PEREZ (*Revista de medicina y cirugía prácticas*, Nos. 554 to 558; *Progrès médical*, January 28th) has analyzed fifty-nine cases of wounds with the machete. Only one was fatal, and death in that case was due to encephalic complications. Notwithstanding the frequency of tetanus in Cuba, in only one case of machete wound did that affection ensue, and in that instance it did not prove fatal.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 4, 1899:

DISEASES.	Week ending Feb. 25.		Week ending Mar. 4.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	18	7	14	3
Scarlet fever.....	170	18	181	13
Cerebro-spinal meningitis.....	0	9	0	9
Measles.....	217	3
Diphtheria.....	184	24	167	27
Croup.....	12	9	9	5
Tuberculosis.....	281	194	244	172
Small-pox.....	0	0	7	1
Chicken-pox.....	43	0	49	0

The New York State Medical Examination.—In the recent report of Dr. M. J. Lewi, secretary of the board of medical examiners representing the Medical Society of the State of New York, we find the following:

"Statistics from the advance sheets of Director Parsons's annual report show the marked superiority of the graduates of New York State medical schools in the licensing tests. From New York State graduates there was an average of one rejected answer paper to three candidates; from graduates of other schools in the United States, an average of one rejected answer paper to each candidate; and from graduates of foreign medical schools an average of two rejected answer papers to each candidate, due partly, perhaps, to ignorance of English. The conclusion is evident that New York State medical schools graduate men better fitted for the practice of medicine than the schools of other States.

"It is the purpose of the board to cooperate with all medical schools in an attempt to elevate the standard of medicine. With this object in view, suggestions and criticisms of our work are not only accepted but invited.

"The board again wishes to state clearly its position regarding exemption from examination in individual cases. When candidates that hold a registered literary degree graduate subsequently from accredited medical schools, and are then licensed by other State boards of medical examiners with standards equal to those required by the New York law, they should be permitted to practise medicine in New York State without the necessity of passing another licensing examina-

tion, provided the regents are satisfied that examination safeguards have been all sufficient.

"We wish to circulate widely the information that it is not our purpose to annoy or hamper competent or skillful practitioners of medicine from other States. The intent of the law is to keep out incompetent practitioners, not to make difficult the licensing of those who are qualified."

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, and cholera were reported to the supervising surgeon-general of the United States Marine-Hospital Service for the week ending March 4, 1899:

Small-pox—United States.

Antauga County, Ala.....	Feb. 24.....	Small-pox present.
Mobile, Ala.....	Feb. 24.....	4 cases.
Montgomery County, Ala.....	Feb. 24.....	Small-pox present.
Denver, Col.....	Feb. 4-11.....	2 cases, 1 death.
Washington, D. C.....	Feb. 23-28.....	11 "
Jacksonville, Fla.....	Feb. 11-18.....	1 case.
Key West, Fla.....	Feb. 25.....	3 cases.
Pensacola, Fla.....	Feb. 27.....	3 "
Savannah, Ga.....	Feb. 22.....	1 case,
		a soldier from Puerto Rico on Str. <i>Chester</i> .
Cairo, Ill.....	Feb. 23.....	9 cases.
Monmouth, Ill.....	Feb. 23.....	3 "
Evansville, Ind.....	Feb. 25.....	1 case.
Jackson City, Ind.....	Feb. 24.....	3 cases.
Peabody, Kan.....	Feb. 16.....	56 " 7 deaths.
Louisville, Ky.....	Feb. 16-23.....	29 "
Baltimore, Md.....	Feb. 8-27.....	2 "
Auburn, Me.....	Feb. 20.....	4 "
Lewiston, Me.....	Feb. 22.....	1 case.
Omaha, Neb.....	Feb. 4-11.....	1 "
Omaha, Neb.....	Feb. 11-18.....	1 "
Providence, R. I.....	Feb. 17-24.....	1 "
Jackson, Tenn.....	Feb. 11-18.....	9 cases.
Memphis, Tenn.....	Feb. 11-18.....	6 "
Alice, Texas, 40 miles west of Corpus Christi.....	Feb. 20.....	20 "
Alexandria, Va.....	Feb. 23-Mar. 2.....	20 " 1 death.
Norfolk, Va.....	Feb. 18-24.....	35 "
Portsmouth, Va.....	Feb. 18-25.....	36 "

Small-pox—Foreign.

Bahia, Brazil.....	Jan. 21-Feb. 4.....	12 cases.
Rio de Janeiro, Brazil.....	Jan. 6-13.....	18 " 7 deaths.
Hongkong, China.....	Jan. 15-21.....	1 case.
Cairo, Egypt.....	Jan. 22-28.....	2 "
Cairo, Egypt.....	Jan. 28-Feb. 4.....	1 death.
Gibraltar.....	Jan. 30-Feb. 5.....	1 "
Gibraltar.....	Feb. 5-12.....	1 "
Bombay, India.....	Jan. 24-31.....	3 deaths.
Ciudad Portillo Diaz, Mexico.....	Feb. 18-25.....	4 cases.
Mexico, Mexico.....	Feb. 10-17.....	10 " 2 "
Moscow, Russia.....	Jan. 28-Feb. 4.....	6 " 4 "
Odessa, Russia.....	Feb. 4-11.....	2 " 1 death.
St. Petersburg, Russia.....	Jan. 21-28.....	2 " 1 "
St. Petersburg, Russia.....	Jan. 28-Feb. 4.....	2 " 1 "
Constantinople, Turkey.....	Dec. 31-Jan. 8.....	18 deaths.
Constantinople, Turkey.....	Jan. 8-Feb. 15.....	14 "
Smyrna, Turkey.....	Jan. 28-Feb. 5.....	1 death.

Yellow Fever.

Rio de Janeiro, Brazil.....	Jan. 6-13.....	28 cases, 20 deaths.
-----------------------------	----------------	----------------------

Cholera.

Bombay, India.....	Jan. 24-31.....	3 deaths.
Calcutta, India.....	Jan. 14-21.....	30 "
Madras, India.....	Jan. 21-27.....	2 "

The Hospital Ship Relief.—The hospital ship *Relief* sailed from New York on March 2d for Manila by way of the Suez Canal. We are informed that she had on board an extra force of men of the hospital corps, several assistant surgeons, and an ample supply of medical supplies and comforts. At Manila we are told that she will act as a hospital ship of three hundred beds.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 4th inst., the following papers were presented: Observations upon the Treatment of One Thousand and One Hundred and Twenty-nine Cases of Acute Alcoholism during the Period of my Official Term of Twenty-five Years as the Physician of St. Vincent's Institution, by Dr. Jerome K. Bauduy; and New Therapeutics of the Tympanic Cavity, by Dr. M. A. Goldstein.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Surgery, on Tuesday evening, the 7th inst., the following papers were presented for discussion: Foreign Bodies in Surgery, by Dr. Chauncey P. Smith; and Urinary Infection and how to Prevent it, by Dr. J. Henry Dowd.

The Eastern Medical Society of the City of New York.—At the last regular meeting, on Friday evening, the 10th inst., the programme included the following titles: A Case of Inoperable Carcinoma of the Thyroid Gland, by Dr. E. K. Browd; A Case of Cretinism after Two Years' Treatment, by Dr. A. E. Isaacs; Large Fibroid of the Uterus removed by Morcellation, saving the Organ, by Dr. H. J. Garrigues; Intralaryngeal Medication with an Intubation Tube, by Dr. Louis Fischer; Specimen of a Gangrenous Appendix, by Dr. Abram Brothers; The Differential Diagnosis of Abdominal and Pelvic Diseases in Woman, by Dr. Paul F. Mundé.

Erratum.—In the third line of Dr. Marx's article on The Treatment of Normal Labor, published in our issue for February 25th, for "sharply defined," read *seldom* sharply defined. The word *seldom* was omitted by the author's copyist, and the omission escaped both his detection and ours.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 25 to March 4, 1899:*

HEYL, ASHTON B., Captain and Assistant Surgeon, will close the general hospital at Fort Thomas, Kentucky, and report to the commanding officer of that post for duty.

POWELL, JERVIS L., Major and Surgeon, is relieved from further duty at Augusta, Georgia, and will return to his proper station, Fort Riley, Kansas.

The following officers of the medical department are honorably discharged from the volunteer army of the United States, to take effect March 23d: **GANDY, CHARLES M.**, Major and Chief Surgeon; **MEAKES, EDWARD A.**, Major and Chief Surgeon; **KENDALL, WILLIAM P.**, Major and Brigade Surgeon; **PLECHER, JAMES E.**, Major and Brigade Surgeon; **LEE, HENRY H.**, Major and Brigade Surgeon; **FARRILL, P. J. H.**, Captain and Assistant Surgeon; and **MILLERS, C. L.**, Captain and Assistant Surgeon.

Society Meetings for the Coming Week:

MONDAY, March 13th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medical Historical Society (private); New York Ophthalmological Society (private); Boston Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston, Burlington, Vermont, Medical and Surgical Club, Norwalk, Connecticut Medical Society (private).

TUESDAY, March 14th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Societies of the Counties of Rensselaer and Ulster (quarterly), N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, March 15th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, March 16th: Missouri Valley Medical Association (St. Joseph); New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

FRIDAY, March 17th: New York Academy of Medicine (Section in Orthopaedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

Births, Marriages, and Deaths.

Born.

JELLIFFE.—In New York, on Wednesday, March 1st, to Dr. and Mrs. Smith Ely Jelliffe, a son.

Married.

COCKS—DONNELLY.—In New York, on Tuesday, February 14th, Dr. Edmund L. Cocks and Miss Anna E. Donnelly.

VALADIER—KARTSCHMAROFF.—In New York, on Tuesday, February 28th, Dr. Charles A. Valadier and Miss Regina Kartschmaroff.

Died.

DEANE.—In Hoosick, N. Y., on Tuesday, February 28th, Dr. Horace C. Deane, aged thirty-five years.

HAINES.—In Tucson, Arizona, on Friday, February 24th, Dr. Franklin R. Haines, aged thirty years.

HOWE.—In Troy, N. Y., on Thursday, March 2d, Dr. Elliot C. Howe, aged seventy-one years.

MARTEL.—In Lewiston, Maine, on Monday, February 27th, Dr. Louis J. Martel.

NICHOLS.—In Brooklyn, on Saturday, March 4th, Dr. Hayden Nichols, in the sixty-fifth year of his age.

RANSLEY.—In Northampton, Vermont, on Wednesday, March 1st, Dr. Stephen F. Ransley, in the seventy-sixth year of his age.

RIEDEL.—In Jersey City, on Saturday, February 25th, Dr. Daniel L. Reeve, in the seventy-fourth year of his age.

SHERMAN.—In Yorkton, N. Y., on Wednesday, March 1st, an infant daughter of Dr. William H. Sherman.

SMITH.—In Brooklyn, on Tuesday, March 2d, Elizabeth J. Smith, wife of Dr. Edward P. Smith.

Wood.—In Havana, Cuba, on Friday, March 3d, Dr. James Wood, United States Volunteer, of Newburgh, N. Y., in the thirtieth year of his age.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

(Continued from page 314.)

IX.

RIGHTS AND LIABILITIES OF THIRD PARTIES.

Who are Third Parties.—The term third party, as used in this article, means any interested person other than the patient. While the physician may consider that he is dealing with the patient individually, it happens more frequently than otherwise that third parties are interested, either having rights of which the physician should be informed and prepared to respect, or incurring liabilities which if understood and taken advantage of may conduce to the physician's financial welfare.

Liability of Third Parties for Fees.—In treating this subject, attention will be first given to the question of when third parties become liable to the physician for the payment of his fees.

Liability of Parent.—That the parent is bound to provide for the maintenance of his minor children is a rule of natural law. But the question to what extent the parent becomes liable for necessities furnished to his minor child is one that is sometimes perplexing. When necessities are furnished, either in the shape of goods delivered or services rendered, with the knowledge and consent of the parent, there can be no question about his liability to pay. But it is laid down as a general rule that no action can be maintained against the parent for goods purchased on credit by his minor child, even though they may be necessary, unless the father has expressly or impliedly authorized the credit.

The authority of an infant to bind his parent for necessities, such as food, clothing, and medical attendance, will be inferred from very slight evidence. The following cases will illustrate the principle:

Illustrations.—If a child who is away from home attending school is taken sick, the parent will be liable to the physician for the amount of his bill, authority to bind the father being inferred from the nature of the case.* A girl of fourteen, with the consent of her father, went to live at a place thirty miles distant, where for three years she contracted for, earned, and controlled her own wages, her father neither furnishing nor agreeing to furnish her with necessities; while these circumstances showed that she was emancipated from the duty of service to the father for the time she was so employed, there was no such complete emancipation as to release him from liability to a physician who attended her in sickness, though the father had no knowledge of such attention.†

And so, where a child leaves home through fear of violence, he carries implied authority to bind his father for necessities.‡ But if the child, having no reason to

fear violence or mistreatment, leaves his father's home without the father's consent, for the purpose of seeking his fortune in the world, or to avoid the discipline and restraint so necessary for due regulation of families, he carries no credit, and the father is under no obligation to pay his necessary bills.*

It will be observed that the case above cited, of the girl who left her father's house and had been employed for three years, is not in conflict with this proposition, for in that case the father had given his consent to the employment. If, however, the child, after leaving home against his father's will, being taken sick, returns home and is received by the father, he becomes liable to the physician for medical services rendered to the child at his house and with his knowledge and assent.†

It seems quite well settled by a number of recent decisions that the parent is bound to pay for necessities furnished to his minor child who is living apart from him with his consent when the parent refuses to furnish them.‡

Upon the death of the father, the mother becomes the head of the family, and is bound by the same obligations of maintenance and support as those which formerly bound the father.

In case of separation or divorce it is of practical value to determine whether the father or mother is liable for necessities for the child. While there are general principles of law governing the liability, it will be impossible to state generally where it rests, an examination into the circumstances of the particular case being always necessary. In case of voluntary separation of the parents the father is *prima facie* liable for the support of the children, though they may be in the custody of the mother; but if the mother, without just cause, leaves the father and takes the children with her, no authority is implied to bind him for their support or necessary expenses, her possession of the children being unlawful.§ But should the court, by a decree or order, give her the custody of the children, then her possession of them becomes rightful and the father becomes liable for their support.||

In Rhode Island it has been held that where the mother wrongfully left the father's home, taking a child, the father, by suffering the child to live separate from him with the mother, constituted her his agent to contract for the child's necessities.¶ When a divorce is granted, the custody of the children is usually regulated by decree. If the divorce is obtained by the wife and the husband is shown to be an improper person to care for and educate the child, the court will decree the custody of the child to the mother. Whether or not the father is liable for the support of the child under such circumstances can not be stated generally, for different rules are applied in different States, and in some States the circumstances of the particular case will govern the matter. In such a case the only safe rule for the physician to be guided by is to have an express contract for

payment with some responsible party before the services are rendered.

When the child becomes of full age a different rule of liability attaches; the parent then ceases to be under obligation to furnish him with necessities, even though he remains at his father's home. It is true the father may become liable for medical attendance upon his adult child by an implied agreement to pay, but it seems the law places the father of an adult child in the same category as a stranger, and will not find him liable on any less or weaker evidence than that required to fix such liability upon a nurse, friend, or acquaintance. So a request by a father to a physician to attend his son, of full age, and at his house, raises no implied promise on the part of the father to pay for such services.* A married daughter of more than twenty-one years of age came with her husband and child to her father's home; she being sick, her husband requested a physician, to whom he was unknown, to call at the house of the father, saying the father wished him to attend his daughter; the physician called, usually met the father, who expressed great interest in his daughter's welfare, expressed a wish to be present at a consultation which was held, and never in any way disclaimed his liability. The court said: "It is true that a person may not avail himself of the benefit of services done for him without coming into an obligation to reward them with a reasonable recompense. But he can not be said, in the meaning of the law, to avail himself of services as so done when they are not for his individual benefit, nor for that of any one for whom he is bound to furnish them. The acquiescence of one in the rendering of service or benefit to another, not entitled to call upon him therefor, is not equivalent to an acknowledgment that it is rendered at his request. So far as the legal responsibility was concerned, the defendant, though the father of the patient, was a stranger to her and her necessities. He could neither require of her, nor be required upon by her."†

Liability of Husband.—The liability of the husband for necessities furnished to the wife is much more certain than that of the parent for necessities furnished to the child; in the latter case there is a question of authority on the part of the child to bind the parent, but in the former case, if the husband and wife are not separated by reason of the improper conduct of the wife, or by reason of her leaving him against his will, almost the only question that can be raised is whether the goods furnished or services rendered were necessary. If the husband and wife are living apart by mutual consent, and the husband has entered into a contract with the wife to furnish her with a certain amount each month for her support and maintenance and all family expenses, and pays such amount, he will still be liable to a physician who renders services to her at her request, the physician not knowing they are living apart and that the husband makes her a fixed monthly payment in lieu of supporting her.‡

It has been heretofore observed that the patient is bound to pay the physician not only for the first visit which is made at his request, but for all subsequent visits when the nature of the case requires; and if the husband who employs a physician to attend his wife is liable for services rendered throughout the ill-

ness. Should the wife be removed to her father's home during her illness, without the husband's knowledge or consent, he will still be bound to pay the physician whom he employed before such removal for services rendered to the wife at her father's home.* If, however, the husband notifies the physician at the time of the removal that he will not pay for services subsequently rendered to her, the physician can not collect from him without showing by clear and satisfactory evidence that the husband was guilty of gross abuse, neglect, and misconduct justifying such removal.

A physician who attends a woman, supposing her to be a wife, can collect for such services from the man holding himself forth as her husband, even though they are not in fact married.† But, it seems, if the physician is cognizant of the fact that they are not married, he can not collect from the supposed husband, unless the supposed husband employed him to render such services, thus becoming liable upon a direct undertaking to pay.

The liability of the husband for necessary food, clothing, and medical attendance furnished the wife in his absence does not include the services of a clairvoyant who does not profess to be a physician or to have any medical skill or knowledge of diseases or their remedies. The court in passing upon this question said: "It does not appear that the plaintiff (*clairvoyant*) professed to be a physician or to have any medical skill or knowledge of diseases or their medical remedies, and of course it does not appear that he has furnished the wife with any necessities within the rule of law for which the husband can be rightfully charged. The law does not recognize the dreams, visions, or revelations of one in a mesmeric sleep as necessary for a wife, for which the husband, without his consent, can be held to pay. These are fancy articles, which those who have money of their own to dispose of may purchase, if they think proper, but they are not necessities, known to the law, for which the wife can pledge the credit of her absent husband."‡

(To be continued.)

SOME OBSERVATIONS ON THE USE AND ABUSE OF QUININE IN THE GROUP OF FEVERS KNOWN AS "CALENTURA."

U. S. A. GENERAL HOSPITAL, DEPARTMENT OF SANTIAGO, SANTIAGO DE CUBA, February 6, 1899.

To the Surgeon-General, U. S. A., Washington, D. C.

SIR: I have the honor to submit the following report:

Many cases of acute quinine poisoning have been brought to my notice since my arrival in this island. The idea naturally followed that if an investigation and observations could be made with smaller doses of quinine or the use of some other drug, better results would follow. Information obtained from native physicians, whose professional education, skill, and mode of observation could not be questioned, also led me to feel that quinine was often administered unnecessarily in the group of fevers known here as "calentura." It was not

* Transmitted from the office of the Surgeon-General of the Army.

unusual in a stubborn case to give as high as a hundred and twenty grains of quinine in twenty-four hours and continue the same treatment for four consecutive days; or, as one of the native physicians graphically expressed it, "continue the quinine until you break the fever or the patient dies." Presuming that but forty grains of quinine can be safely administered and absorbed during a period of twenty-four hours, and that this amount must not be too long continued, it is safe to say that more than this amount would act as an irritant to the gastro-intestinal tract, and as a depressor of the nerves of the hæmatopoietic system. When the line of treatment is followed as indicated by the native physicians, the patient is left almost stupefied and in an anæmic and nervous condition, the stomach very irritable, with a distaste for food, and a very tedious and unsatisfactory convalescence follows. That this method of practice had rapidly obtained a foothold among the surgeons on duty with the Fifth Army Corps, and the Department of Santiago, was but too evident. I have personal knowledge of many cases wherein quinine was given *ad libitum*, both as to frequency and quantity, and know personally of several cases wherein from a hundred to a hundred and twenty grains were given daily for a period of from six to eight days consecutively. There are without doubt forms of malaria where quinine must be pushed to the maximum. I refer to those types of congestive and algid remittent fevers where the patient's life is in great danger from profound malarial intoxication. In such cases a hypodermic injection of quinine in combination with urea is much to be preferred, for obvious reasons. The combination of the quinine and urea forms a perfect solution, and, being alkaline, the quinine will not be precipitated when coming in contact with the alkaline juices of the body. So far as my observation has gone, I have met with no case where urea in this combination exerted any deleterious action upon the system. The advantage, therefore, of this combination is self-evident, and it also prevents the enormous dosing above referred to.

Lieutenant-Colonel Havard, chief surgeon of the Department of Santiago, had spoken with me on several occasions concerning the large doses of quinine given in this climate, and had expressed his desire to have an effort made, if possible, to treat a certain number of these cases without the use of quinine or with quinine in much smaller doses.

With the above-stated facts in mind, the following line of medication was begun in one of the wards of this hospital within a few days after I was placed in charge. The cases reported are not so full as I should have wished them to be, for the reasons that the staff of medical officers was small, the number of patients was large, and the facilities at the time for thorough scientific work were wanting.

The cases were grouped into two classes:

Class "A," cases of patients who had not received

previous medication, and wherein after their admission to this hospital no quinine was given, and an original line of treatment adopted and carried out.

Class "B," cases wherein the previous history was obscure and the details of previous medication could not be ascertained, and wherein quinine was given during the patient's stay in this hospital.

Class "A" only will be reported in this paper.

Class "A."

CASE I.—Isaac Morris (colored), civilian employee of the quartermaster's department, admitted October 19th, at 12 M., with a temperature of 100.8° F.; pulse, 100; respiration, 22. Previous history negative. Present illness began with a chill on the morning of the 17th, followed by fever. The paroxysm recurred on the following day and on the morning of admission to this hospital. Patient was given a cold bath and placed in bed on a liquid, sustaining diet. To overcome the existing constipation, half a grain of calomel was given every hour until two grains were taken, followed by a saline cathartic, with satisfactory result. Antipyrine, five grains, was then administered and repeated at 3 P. M. The temperature at 7 P. M. was 99.2° F. On the following day it was normal in the morning and the evening, having risen to 99° F. at noon. The temperature continued normal during his stay at this hospital. All this time the patient appeared comfortable. No other medical treatment was resorted to excepting tonic doses of tincture of chloride of iron. The patient was discharged, recovered, on October 27th. Diagnosis, intermittent malarial fever.

CASE II.—James Gaskill (colored), civilian employee of the quartermaster's department, admitted October 19th, at 12 M. Previous history uninteresting. His present illness began with a severe chill on the 17th, accompanied by nausea and vomiting. These attacks recurred on the 18th and 19th, when he applied for treatment. His temperature on admission was 105.4° F.; pulse, 102; respiration, 28. The temperature was reduced by cold sponge baths given at hourly intervals. Antipyrine, in five-grain doses, was given at 2 and 4 P. M. A saline cathartic was administered with good result. Apollinaris water and Rhine wine were ordered, to combat nausea. At 4 P. M. the same day the temperature was 102°; at 7 P. M. it was 102.8°; pulse, 96; respiration, 22. On October 20th, at 7 A. M., the temperature was 100°; pulse, 80; respiration, 28. Antipyrine repeated. Tincture of chloride of iron, twenty drops, and tincture of nux vomica (Spanish mixture), three-drop doses (this tincture is of treble the strength of the tincture of the *United States Pharmacopæia*), given three times a day. At 12 M. the temperature was 100.6°; pulse, 80; respiration, 28. At 7 P. M. the temperature was normal. There was no chill and the patient seemed to be comfortable. This condition continued until October 28th, when the patient was discharged, recovered. He has been in the employ of the quartermaster's department since then, and has remained perfectly well up to the date of this report, January 10, 1899.

CASE III.—Robert Stanley (colored), civilian employee of the quartermaster's department, admitted October 20th, at 11 A. M. Previous history negative; habits good. Was taken ill with a chill on the morning of admission. Temperature on admission, 101.4° F.;

pulse, 96; respiration, 28. Received a cold bath and five grains of antipyrine. At 5 p. m. the temperature was 102.8°; at 8 p. m., 102°. On October 21st the temperature was normal, and remained so during the entire day. Gave tincture of chloride of iron, twenty drops, and liquor potassii arsenitis, three drops, three times a day, after meals.

22d.—7 A. M., temperature normal; 3 p. m., 100.2° F.; 5 p. m., 104.4°; 8 p. m., 102.6°. No chill preceded this sudden rise in temperature. He received two baths at intervals of an hour. He was constipated; relieved by half-grain doses of calomel administered at hourly intervals until two grains were taken, followed by a saline laxative.

23d, 7 A. M.—Temperature normal. Continued the tincture of chloride of iron and liquor potassii arsenitis. No rise of temperature occurred on the 24th, 25th, 26th, 27th, and 28th, and he was discharged, recovered, on the 28th. Diagnosis: malarial intermittent fever.

CASE IV.—Henry A. Peters (white), civilian employee of the quartermaster's department, admitted October 22d, at 1.30 p. m., with a temperature of 102.4° F.; pulse, 96; respiration, 23. Family history good; denies alcoholism and specific disease. No history of previous illness. Patient received a cold bath, and his temperature fell to 102°. The constipation was relieved with a saline cathartic, with good result. On the following day, October 23d, he received five grains of antipyrine at 9, 1, and 5, the temperature record being 101° at 7 A. M., 101.4° at 12 M., and 102° at 7 p. m. On the 24th, at 7 A. M., his temperature was 99°; at 12 M., 98.4°; and at 7 p. m., 101.2°. The antipyrine was repeated. On the 25th his temperature was normal and remained so all day. He was now placed on tincture of chloride of iron and Fowler's solution, given in combination after each meal, as continuous medication. He was discharged, recovered, on the 29th. When he was seen, a month later, fever had not returned, and he seemed perfectly well.

CASE V.—William Campbell (colored), civilian employee of the quartermaster's department, admitted October 20th, at 3.30 p. m., with a temperature of 102° F. Previous history negative, family history good, of regular habits. Present illness began ten days ago with severe chills and fever every other day. On the morning of admission he had a severe chill, soon followed by marked nausea and vomiting. He was placed in bed, on a liquid sustaining diet, and given five grains of antipyrine at 4 and 6 p. m. The nausea persisting, he was given creosote in small doses with marked benefit. On the 21st the temperature was normal and the patient appeared to be very comfortable. There was no rise of temperature on the 22d. The following day, the 23d, the patient had a severe chill at 2.45 A. M., lasting about twenty minutes. He received half an ounce of whisky and a cold pack. At 7 A. M. his temperature was 101.4°. During the entire day and all during the period of his stay in this hospital the temperature continued normal. He was placed on the Fowler's solution, three-drop doses, after meals. On the 28th he was returned to duty, and when he was last seen, about December 25th, his condition was excellent and the fever had not returned.

CASE VI.—Herbert Graham (white), civilian employee of the quartermaster's department, admitted November 1th, at 4 p. m., with a temperature of 101° F. Previous history negative, family history unascertained. Habits good. His present illness began three days prior

to his admission, with a severe chill followed by fever. The paroxysm recurred every morning. He was constipated and a saline cathartic was administered with good result. A cold bath reduced his temperature to 102° at 6 p. m. On the 8th, at 7 A. M., his temperature was 98°, and remained normal throughout the day. He was given ten-drop doses of tincture of chloride of iron after meals. On the 9th his temperature was normal, and continued so until the 14th, when it rose to 99.4° at 4 p. m., and then five grains of antipyrine were administered. On the 15th, at 7 A. M., his temperature was 99°, at 12 M. 98.8°, and at 4 p. m. 99.2°. Antipyrine was repeated. On the 16th his temperature was normal throughout the entire day, and it continued so until the evening of the 17th, when it rose to 99.6° at 7 p. m. Five grains of antipyrine were administered. From that time on his temperature remained normal till the 23d, when he was returned to the quartermaster's department for duty.

CASE VII.—J. G. Walker (white), civilian employee of the quartermaster's department, admitted November 10th, at 8 p. m., with a temperature of 102.6° F. Family history good. On admission he was placed in a cold bath, the temperature falling to 100° F. Five grains of antipyrine were given. On the 11th, at 7 A. M., his temperature was 99°, at 12 M. 99.8°, and at 4 p. m. 99°. Antipyrine was repeated at 1 and 4 p. m. On the 12th his temperature was normal, and he was placed on Fowler's solution, three times daily, after meals, for continued use. On the 13th his temperature was normal, and remained so until 3 A. M. November 14th, when he had a chill, followed by a temperature of 102°. He received five grains of antipyrine, and at 7 A. M. the thermometer registered 101°. At 12 M. his temperature was 99°, rising to 101° at 4 p. m. Antipyrine was repeated at 3 and 5 p. m. On the 15th, at 7 A. M., his temperature was 99.6°, at 12 M. 98°, at 4 p. m. 98.2°. On the 16th, at 7 A. M., his temperature was 100°, but normal during the rest of the day. From that time on his temperature never went above 98.2°, and he was discharged at his own request on the 20th.

CASE VIII.—Charles Barrett (white), civilian employee of the quartermaster's department, admitted November 12th, at 6 p. m., with a temperature of 102.6° F. He was considerably nauseated and vomited several times. He received a cold bath every hour and five grains of antipyrine every forty-five minutes. His temperature at 9 p. m. was 101°. On the 13th, at 7 A. M., it had dropped to 100°, and at 12 M. to 98°, but rose again at 4 p. m. to 105.2°. He received a cold pack, which reduced his temperature to 101°. Another cold bath at 5 p. m. lowered the temperature to 102.6°. The bath was repeated at 6 p. m., followed by a drop in the temperature to 101.4° half an hour later. His bowels were very much constipated and did not respond to a saline cathartic, which had been administered previously, but moved well after a copious rectal injection. At 5 A. M. on the 14th he had a severe chill followed by a temperature of 102°. Five grains of antipyrine and a cold bath caused a drop in the temperature to 100.2°. At 4 p. m. the same day it rose to 102.4°. On the 15th his temperature ranged from 97.6° to 98.2°. He was now placed on the continued use of iron and at once after meals. The temperature continued normal until the 18th, when it was 99° at 7 A. M., 101° at 12 M., and 101.4° at 4 p. m. He received five grains of antipyrine, and the temperature on the following day had fallen to 97.2°. He was anxious to return to work, and left the hos-

pital, in good condition, on the 20th. He returned a month later with an attack of acute diarrhoea, but stated that he had been entirely free from fever.

CASE IX.—James Belcher, civilian employee of the quartermaster's department, admitted November 20th, at 8 p. m., with a temperature of 105.4°. Previous history not ascertained. States that on the morning of admission to this hospital he had a violent chill. On the 21st, at 7 a. m., his temperature was 99°, and ranged between 98.5° and 98.6° during the day. He was placed on liquid and stimulating diet, but medication was withheld. On the 23d his temperature was normal during the day, and stimulating diet was continued. On the 23d tincture of chloride of iron, twenty drops, was ordered three times a day. On the 23d, 24th, 25th, and 26th the diet and stimulants were continued. His temperature was normal during this period. On the 27th his temperature was normal until 4 p. m., when it rose to 100.4°. There was no chill. On the 28th, at 7 a. m., his temperature was 102.3°; there was no chill. At 12 m. it was 103.6°; at 4 p. m., 103.4°. Antipyrine in five-grain doses was given at 2 and 4 p. m. He had a cold bath and was put on liquid diet. On the 29th, at 7 a. m., his temperature was 100.6°; at 12 m., 101°; at 4 p. m., 102.4°. One five-grain dose of antipyrine was given. On the 30th, at 7 a. m., his temperature was 100.2°; at 12 m., 99.4°; at 4 p. m., 100.6°. On December 1st, at 7 a. m., his temperature was 99.8°; at 12 m., 102°; at 4 p. m., 100.6°. On the 2d, at 7 a. m., his temperature was normal; at 12 m., 99.8°; at 4 p. m., 100.6°. On the 3d, at 7 a. m., it was 102.2°; at 12 m., 100.4°; at 4 p. m., 102.4°. Antipyrine, five grains, was given, also a cold bath. This treatment was continued. On the 4th, at 7 a. m., his temperature was 98°; at 12 m., 98.6°; at 4 p. m., normal. It varied between 97.4° and 98.8° until he was discharged on the 12th.

CASE X.—William J. Coughtry (white), sergeant, Third Company, United States Volunteer Signal Corps, admitted at 5 p. m., November 21st, with a temperature of 105° F.; pulse, 120; respiration, 26. He had had pneumonia several weeks before, which left him with a severe cough. States that he had a chill on the morning of admission, but none previously. At 6 p. m. his temperature had risen to 105.6°. There were some nausea and vomiting and he complained of severe headache. There was some diarrhoea. He received five grains of antipyrine at 6 and 7 p. m., and ten grains of Dover's powder at 8 p. m., followed by one one-hundredth of a grain of digitalin. On the 22d, at 7 a. m., his temperature was normal, at 12 m. 99°, and at 4 p. m. 101.4°. He received five grains of antipyrine. The following morning, at 7 a. m., the temperature was 103°, which was reduced by a cold bath to 101.2°. At 12 m. it was 101.6°; at 4 p. m., 101.4°. Antipyrine was repeated, and the patient perspired very freely. On the 24th, at 7 a. m., his temperature was 100°, and remained so till the following day, when it rose to 102° at 2 p. m. At 4 p. m. it remained high, and five grains of antipyrine were given. On the 26th and 27th it ranged between 100° and 100.6°, falling to 99° on the morning of the 28th. On the 29th, at 7 a. m., his temperature was 99.4°, at 12 m. 100°, and at 4 p. m. 99°. On the 30th the temperature was normal, and continued so until his discharge on December 6th. During his convalescence he was placed on small doses of strychnine and arsenic after meals.

CASE XI.—W. T. Phillips (white), private, Fifth United States Volunteer Infantry, entered this hospital

on November 23d, at 7 p. m., with a temperature of 102.6° F. He received two cold baths, reducing the temperature to 100° by 11 p. m. On the 24th, at 7 a. m., his temperature was 99°, at 12 m. 100°, and at 4 p. m. 103.8°. The bath was repeated and five grains of antipyrine were administered. At 5 p. m. his temperature was 102°. On the 25th, at 7 a. m., his temperature was 101.2°, at 12 m. 103.2°, and at 4 p. m. 105.2°. He received two cold baths at short intervals, followed by a cold pack, which reduced the temperature to 103°. On the 26th, at 7 a. m., his temperature was 100°, at 12 m. 98.6°, and at 4 p. m. 99°. On the 27th and 28th his temperature ranged from 99.4° to 100°. On the 29th it was normal, and continued so until he was discharged, on December 1st.

CASE XII.—Charles W. Ryan, a civilian employee of the quartermaster's department, was admitted on November 23d, at 4 p. m., with a temperature of 104° F. His illness began with a continued fever five days before his admission. A cold bath was ordered, and five grains of phenacetine were administered, resulting in a dropping of the temperature at 7 p. m. to 100.4°. On the following day his temperature was 101.4° at 7 a. m., 99.6° at 12 m., and 101.3° at 4 p. m. The phenacetine was repeated. On the 25th, at 7 a. m., his temperature was 100.2°, at 12 m. 99°, and at 4 p. m. 100.4°. After the 26th it continued normal, and he was finally discharged on the 9th of December.

CASE XIII.—Alonzo Curry, corporal, Ninth United States Volunteer Infantry, was admitted on October 20th, at 11 a. m., with a temperature of 104.8°. His health had always been good until a few days prior to his admission. A cold bath was then given, the temperature being 103.2° at 4 p. m. Five grains of antipyrine were administered, which reduced the temperature to 102° at 7 p. m. In order to relieve constipation, half a grain of calomel was given every hour until two grains were taken. On the 21st his temperature was normal until 4 p. m., when the thermometer registered 103.6°. The antipyrine was repeated at 4 p. m. and again at 5 p. m. At 7 p. m. his temperature was 103.4°. On the following day the temperature had again risen to 103.8° at 7 a. m., at 12 m. to 104°, reaching its maximum at 4 p. m., 104.4°. He had received a cold bath at 12 m., and one at 2 p. m., also five grains of antipyrine at 5 p. m. On the 24th his temperature was 101.4° at 7 a. m., 102.3° at 12 m., and 104.4° at 4 p. m. Two cold baths were given, reducing the temperature to 102° at 7 p. m. The following day the temperature remained normal. As the patient was somewhat constipated, calomel in divided doses was given with good result. On the 26th the temperature was 99° at 7 a. m., 100° at 12 m., and 101° at 4 p. m., falling somewhat after a cold bath. On the 27th the temperature was normal. On the morning of the 28th the temperature had again risen at 7 a. m. to 100°, dropping to 99.2° at 4 p. m. On the 29th it was 99° at 7 a. m., but remained normal during the entire day, and until the 30th, when it rose to 101.6° at 7 a. m. At 12 m. it had dropped somewhat, being 100.6°, but had risen again to 102° at 4 p. m. On the 31st, at 7 a. m., it was 100°, and continued so until November 2d, at 12 m., when it dropped to 99°. At 4 p. m. it was 99.2°. On the 3d, at 7 a. m., it was 102.6°. At 12 m. it was 102°, and at 4 p. m. 100°. On the 4th it remained normal, and continued so till the 5th, at 7 a. m., when he had a chill, followed by a rise in temperature to 101°, gradually dropping to normal. On the 6th the temperature fluctuated between 98° and 99°. On the

7th it rose again to 100° at 7 A. M., at 12 M. it was 99° , and at 4 P. M. 99.4° . On the 8th, at 7 A. M., it was 98.4° , at 12 M. 99.8° , and at 4 P. M. 99° . On the 9th it was normal. On the 10th it rose to 99.4° at 4 P. M. On the 11th, at 5 A. M., he had a chill, followed by a temperature of 100° at 7 A. M. At 12 M. it was 99° , and at 4 P. M. 101.6° . From the 11th to the 21st he was entirely free from fever, but was then taken again with a chill at 12 o'clock, followed by a temperature of 101.6° at 2 P. M. At 4 P. M. it had dropped to 100° . He was given five grains of antipyrine. Now follows another period of intermission, when his temperature was normal and he appeared comfortable until December 1st, when he contrived to overload his stomach, and he became very much constipated, the temperature rising to 102.2° at 7 A. M. and 104° at 12 M. He was given an emetic and an enema with very good result. This was followed by a drop in the temperature to 99.4° at 7 P. M., without any further medication. From this time on, until the 20th, the patient was entirely free from fever, and was finally transferred to duty, fully recovered.

There can be no reasonable doubt that the cases given were all of malarial origin, although clinical data are defective, and microscopical tests were impossible, for lack of a pathologist or facilities for making the necessary examination. The cases cited above were placed in charge of Acting Assistant Surgeon, United States Army, Milton Vaughan. He was also in charge of the typhoid fever and dysentery ward, where he was kept very busy, and consequently neglected to obtain more data in these cases, and he did not regard them as of equal importance with those of his other patients.

The conclusion that may be drawn from these cases is that, in cases of mild malarial poisoning, the patients who received no quinine convalesced more rapidly and the recovery was far more satisfactory than in cases of the same class which had been treated in this hospital with quinine *ad libitum*. I am referring to cases of which I have personal knowledge, some of the patients being still in this hospital, where the average length of their stay had been about three months and quinine was given in large doses long continued. They are still anæmic, with capricious appetites, and their convalescence is very tardy and unsatisfactory. Their sense of hearing and nerve centres are at least temporarily impaired, with a tendency to recurrence of malarial paroxysms.

There are some cases of more profound malarial intoxication which have been treated with quinine not to exceed eighteen grains daily, and this amount not continued longer than three days. Daily tests of the blood have been made by Acting Assistant Surgeon, United States Army, F. W. Fabricius, pathologist at this hospital. Three of these cases are completed, but others are still under observation; and when ten or twelve cases have been completed a further report will be made. Observations will also be continued in the milder form of malarial poisoning along the lines indicated in the paper.

The fact that many of the subjects of sickness occurring during August, September, and October recovered under treatment other than the use of quinine was used by some of the physicians sent here as an argument that all such cases were yellow fever. I mention this circumstance simply to show that the reports of the yellow fever epidemic here in the summer could have been greatly exaggerated if the fact above mentioned had been taken as confirming a diagnosis of yellow fever.

I am under obligations to Acting Assistant Surgeon, United States Army, F. W. Fabricius, pathologist at this hospital, for assistance in collating these cases.

Very respectfully,

[Signed.]

L. C. CARR,

Major and Brigade Surgeon, United States Volunteers, Commanding General Hospital.

Letters to the Editor.

A "PSYCHOPATHIC" HOSPITAL.

44 EAST TWENTY-SIXTH STREET, March 4, 1899.

To the Editor of the New York Medical Journal:

SIR: The establishment of unneeded hospitals and dispensaries in this city and elsewhere has been so frequent in the past that one is tempted to question the motives of the proposers of new schemes. In a daily newspaper a few weeks ago, and again in your journal, the project of inaugurating what is somewhat pedantically and erroneously called a "psychopathic" hospital for the treatment of acute cases of insanity is exploited. Your contributor, Dr. Lyon, the medical superintendent of Bloomingdale Asylum, is the head of an institution which has repeatedly announced its desire to receive only acute cases, and its refusal as far as possible to take those of a chronic nature. It is, or ought to be, in every sense a charitable institution, for it pays no State tax, is richly endowed, and, though it is somewhat inaccessible, because for economic and other reasons it was moved to White Plains, its laudable existence as a hospital for acute cases should fully satisfy those physicians who demand improvements. The State should very properly have nothing to do with the local treatment of the insane poor of New York, any more than it should with the control of the Bellevue, Roosevelt, Presbyterian, Mount Sinai, or St. Vincent's Hospital. What is really needed is an observation and detention hospital, which should be an amplification of the existing pavilion at Bellevue, with certain reforms in management now most urgently needed, including the abolition of the fee commitment system and the severance of any connection between the city institution at the foot of Twenty-sixth Street and private asylums, to which it is often a feeder. The resident and consulting physicians should be chosen after competitive examination, holding their place for a definite term, and all commitment papers should be sent to the Bellevue board. If this were done, one of the objects might be corrected, and the danger of the patients being placed upon such a plan as to be unable to leave, and afford a field for satisfactory chemotherapy.

If conducted on these lines, without the blight of politics, we should not need a "psychopathic" hospital, which under any circumstances is out of place in a noisy city.

ALLAN McLANE HAMILTON, M. D.

ANAPHORIA AND CATAPHORIA.

1427 WALNUT STREET, PHILADELPHIA, March 6, 1899.

To the Editor of the New York Medical Journal:

SIR: With a desire for accuracy, and that credit should be given to whom it is due, I address your columns. In Dr. Ranney's book entitled *Eye Strain in Health and Disease*, on page 35, I note the following: "Terms relating to the muscles which move the eyes" (muscular terms). "These were first suggested by George T. Stevens." I refer especially to the one term, *anotropia*, an actual turning of both eyes upward." Again, on page 59, he says: "Within the past two years the attention of oculists has been drawn by my friend Dr. G. T. Stevens, of New York, to certain abnormal conditions of the orbit in which both eyes simultaneously tend to assume too high or too low a plane in the orbit." If I am not mistaken, Dr. Chalmers Prentice, of Chicago, was the first to call attention in medical literature to the fact that both eyes might tend upward or downward. In *The Eye in its Relation to Health*, page 166, beginning at the fifteenth line, he says: "By considering only the relative position of the two eyes, we are likely to overlook some grave defects in the ocular muscles, for it is possible for both of the superior or inferior muscles to be short, in connection with a relative deviation or relative balance." I do not recall the exact date of Dr. Stevens's article in the *New York Medical Journal* in which he mentions the fact that both eyes may turn upward; I think it was between one and two years after the publication of Dr. Prentice's book. If I am correct in this, Dr. Prentice should be credited with first calling attention to the condition, although he did not give it a name.

SAYLOR BROWN, M. D.

BRONCHOPNEUMONIA FROM THE INHALATION OF A FOREIGN BODY.

SLAYTON, MINN., March 1, 1899.

To the Editor of the New York Medical Journal:

SIR: In a late number of the *New York Medical Journal* there is recorded a case of Bronchitis and Pneumonia following the Inhalation of a Foreign Body, by C. E. Coon, M. D.

I wish to add to the record the following, which occurred in my practice: On December 25, 1897, I was hastily summoned to attend a child eight months old in a paroxysm of coughing, which was caused by a piece of peanut being inhaled. The parents were feeding the child with peanuts, and a part of one was inhaled involuntarily. The child was cyanotic, with increased rapidity of respiration, and in twenty-four hours she had all the symptoms of broncho-pneumonia, with high fever and with sibilant and subcrepitant râles over the left side of the chest. These symptoms persisted for three or four days, when the patient seemed to improve, with slower respirations, lower pulse, and less cyanosis. No further advance toward health was made; the disease was stationary, and the left side of the chest did not clear up. The child was very much emaciated and growing slowly weaker until six weeks after, when,

during a paroxysm of coughing and vomiting, a segment of a peanut was expelled, flat on one surface, convex on the other, and measuring a half by one centimetre. The child was in excellent health in about ten days, and is strong and robust at this time.

HARRY MORELL, M. D.

AN AUTHOR'S COMPLAINT.

1504 PINE STREET, PHILADELPHIA, February 17, 1899.

To the Editor of the New York Medical Journal:

SIR: In your review of my book in the issue of January 7th, your reviewer departs from the recognized custom of expressing more or less correct opinions and loses himself in a series of misstatements of fact to which I courteously call your attention.

1. He says the book is made up largely of quotations from three named text-books on the subject of pædiatrics, of which one is by Starr. Neither my colleague Dr. Wells nor I have seen this work. There is a text-book edited by Starr to which I am a contributor.

2. That these quotations are oftentimes "whole pages in length."

3. That the book "abounds in coined words."

A casual glance at the volume will show the statements to be false.

J. MADISON TAYLOR, M. D.

Book Notices.

Die Krankheiten des Mundes. Von J. MIKULICZ, Direktor der chirurgischen Universitäts-klinik, und W. KÜMMEL, Leiter der Universitäts-poliklinik für Ohren-, Kehlkopf- und Nasenkrankheiten, in Breslau. Mit Beiträgen von A. CZERNY, Direktor der Universitäts-kinderklinik, und J. SCHAEFFER, Privatdozent für Dermatologie in Breslau. Mit 2 lithogr. Tafeln und 62 Abbildungen im Text. Jena: Gustav Fischer, 1898. Pp. ix-253.

It is a pleasure rarely vouchsafed to the reviewer to read and pass judgment upon so satisfactory a volume as the one before us. In the writing of it the general knowledge of an operating surgeon has been combined with that of a specialist devoted to a daily study of the mouth and throat. The senior author regrets the lack of special study of this portion of the human anatomy, and points out that, while we may have throat and nose specialists and dentists, yet no one thinks the tongue and mouth worthy of undivided attention. To fill this blank in medical science and to form the complement of another work by Mikulicz (*Atlas of the Diseases of the Mouth and Pharynx*) are the functions of the present volume. It is divided into a general part, devoted to an anatomical introduction, with suggestions for the routine examinations of the mouth and the general symptoms to be expected in oral diseases, and a special part, in four divisions, allotted respectively to those conditions which involve the mouth as a whole, to conditions localized in a particular part of the mouth, to tumors, and to those diseases especially noticed in children. The first division is chiefly taken up with syphilis and oral tuberculosis. Under leucoplakia we note that the syphilitic origin of the disease is still recognized, or, rather, the disease is now considered a parasyphilitic process, to be more accurate, just as tabes is now classified.

The remainder of this section includes the rarer conditions which may give rise to well-marked lesions in the mouth, among them glanders, leprosy, and actinomycosis. The portion devoted to tumors is, however, the most interesting and instructive. With the exception of the epitheliomata of the lip and tongue and epulis, tumors of this region are comparatively rare, and yet we find seventy-six pages devoted to this subject, every point of which is illustrated by suitable cases from the authors' experience and embellished with many photographs and drawings.

An appendix at the end of the book gives formulae which the authors have found useful for the treatment of the diseases of the mouth. This volume as a whole is a credit to German scholarship and patient research, and as a mere example of the value and methods of recording personal observations should inspire similar results in this country, where they are, unfortunately, altogether too rare.

Leçons de clinique chirurgicale faites à l'Hôtel-Dieu (août-septembre, 1897). Par PIERRE DELBET, Professeur agrégé à la Faculté de médecine, etc. Avec 31 figures. Paris: G. Steinheil, 1899. Pp. 376. [Prix, 8 fr.]

THESE lectures on clinical surgery cover a considerable variety of subjects, from otitis media to contraction of the plantar fascia. The first is devoted to the methods used in the restoration of the congenital defects of the hard palate, and a large part of the article is given up to the discussion of the best age for the carrying out of the operation. Delbet inclines strongly to a late operation, even at the age of six or seven years, but insists that good results are more easily obtainable if the child has had a careful preliminary training, so that it may speak as well as possible before the operation.

An especially interesting presentation is given of the rather hackneyed subject of varicose veins, and the methods of determining the efficiency of the valves in the saphenous, a point of prognostic as well as of diagnostic value, are well described and illustrated. The recent investigations on the congenital absence of these valves as the real exciting cause of the varicosities, appearing perhaps only late in life, are not mentioned. Enough has been said, we think, to show the valuable nature of these recent contributions to surgical literature.

BOOKS, ETC., RECEIVED.

The Retrospect of Practical Medicine and Surgery. A Half-yearly Journal containing a Retrospective View of Every Discovery and Practical Improvement in the Medical Sciences. Edited by James Braithwaite, M. D. Lond., Obstetric Physician and Surgeon to the Leeds General Infirmary, etc., assisted by E. F. Trevelyan, M. D. Lond., B. Sc., M. R. C. P., Assistant Physician to the Leeds General Infirmary, etc. Volume CXXIII. January, 1899. Uniform American Edition. New York: G. P. Putnam's Sons, 1899. Pp. xvi 435. [Price, \$1.50.]

Gout: its Pathology and Treatment. Founded on the Goul-toumian Lectures on *The Chemistry and Pathology of Gout*, delivered by the Author before the Royal College of Physicians of London in 1897; with the Addition of Some Recent Investigations concerning the Treatment of Gout, and a Detailed Account of the Treatment of the Various Forms of Gout. By Arthur P. Luff, M. D. Lond., B. Sc., F. R. C. P., Physician in

Charge of Out-patients, and Lecturer on Forensic Medicine at St. Mary's Hospital. New York: William Wood & Co., 1899. Pp. viii-248.

An Experimental Research into Surgical Shock. An Essay awarded the Cartwright Prize for 1897. By George W. Crile, A. M., M. D., Ph. D., Professor of the Principles of Surgery and Applied Anatomy in the Cleveland College of Physicians and Surgeons, etc. Philadelphia: J. B. Lippincott Company, 1899. Pp. 5 to 160. [Price, \$2.50.]

Behandlung der Lungentuberculose mit subcutanen Injectionen von Oleum camphoratum oleumale Pharm. Germ. Von Dr. Bruno Alexander, Nervi und Beidenhüll. [Sonderabdruck aus der *Berliner Klinische Wochenschrift*.]

Miscellany.

Subcutaneous Administration of Egg Yolk in Malnutrition. According to Mergel's *Prescriptions for Pharmacy*, A. Muggia (*Scienze e Arti*, xv, 1898, 270) states that egg yolk may be advantageously substituted subcutaneously, instead of feeding, in case of malnutrition in children. For the preparation of the injection, the egg yolk,

obtained from a fresh, carefully washed egg, is mixed with one third of its weight of physiological sodium-chloride solution in a sterilized glass by stirring with a glass rod, and the mixture is then strained through absorbent gauze. The initial dose of the solution is a cubic centimetre, and the injections are to be made in the buttocks or lumbar region. There is no manifestation of local or general reaction, provided that the usual aseptic precautions are taken, and that a light massage is practised after the injection. The quantity injected each time may be increased up to but not beyond ten cubic centimetres, and the duration of treatment depends on the condition of the patient. The number of injections should not, however, be less than twenty. This treatment, it is asserted, rapidly increases the weight of the atrophic child, as well as the hæmoglobin content and red corpuscles of the blood, and much more rapidly than lecithin does when administered similarly.

The Medical Treatment of Appendicular Inflammation.—Dr. Herman B. Allyn (*Therapeutic Gazette*, January 16th) says:

"But even the most enthusiastic advocates of operation decline to operate in certain cases. I very well remember on one occasion calling a surgeon in consultation over a case of appendicitis. There was extensive tympanites but only slight fever, and the pulse was under 100. The aspect of the patient was, however, bad, and the surgeon declined to operate then, believing that if the abdomen were opened the patient would go into collapse and die on the table. He advised the use of Epsom salt until the bowels were freely moved. This suggestion was carried out, and in twelve hours the patient was so much better that it was decided to wait still longer before operation. To make the story short, the patient fully recovered, and then declined operation, until another attack made him again change his mind. It may appear to others, as it seemed to me, that if the moderate use of salines will rescue a patient who is deemed so far gone by a surgeon that he would not survive an operation, it should also be a good treatment for milder cases in which the question of operation is never urgent."

The Pulse and the Blood Pressure.—Dr. George Oliver (*Clinical Journal*, February 1st) thus epitomizes the leading signs of increased and diminished arterial blood pressure. In increased arterial pressure—1. The artery is felt to be full, and can often be rolled under the finger. 2. The tetus or beat of the pulse is prolonged, a quality which is not recognized under a light touch, the swell and duration of the pulsation increasing with the compression. 3. The pulse is only obliterated under increased pressure, the finger, however, very frequently failing to recognize this fact when the calibre of the radial artery is reduced. 4. The hæmodynamometer amplifies all these tactile signs of the pulse, and defines the blood pressure with certainty and accuracy. 5. The blood pressure, arterial and venous, is frequently uniform, or alters but little on changes of posture, and the radial pulse is well sustained when the wrist is elevated above the head (the gravity test). 6. The venous blood pressure may be normal, or may be increased when the peripheral resistance is compensated; or it may be subnormal, or even so low as to be immeasurable when the peripheral resistance is so excessive as to reduce the high arterial pressure to a minimum or to zero in the veins. 7. The second aortic

sound is generally accentuated. 8. The apex-beat is frequently moved to the left of its normal position. 9. The breathing is easily disturbed by slight exertion.

In diminished arterial pressure we have the following signs: 1. The artery is flaccid and can not be felt. 2. The beat of the pulse is short and full, a quality easily recognized under the lightest touch—that is to say, with little more than the mere weight of the finger upon the artery. 3. The pulsation is obliterated under slight compression. 4. On applying the hæmodynamometer the index begins to pulsate under a low pressure, and soon attains its maximum excursion. 5. The blood pressure, arterial and venous, always varies considerably with changes of posture, generally falling with recumbency, but sometimes rising for a time with the assumption of that posture when the arterial tonus is greatly reduced and the radial pulse is greatly lessened, or may even vanish when the wrist is raised above the head. 6. The venous pressure is generally normal, or may be in excess of normal, but is sometimes reduced from diminished *vis a tergo*, and not from obstruction of the peripheral vessels.

The Penalty of being Before the Age.—Dr. Priestley Leech (*Quarterly Medical Journal for Yorkshire and Adjoining Counties*, January) delivered a most interesting presidential address before the Halifax (England) and District Medical Society on The Influence of the Provinces on the Progress of Medicine and Surgery. He quotes Watson Cheyne as saying, in an article on The Progress of Surgery during the Queen's Reign, that three things rendered progress in surgery possible, and these were anaesthesia, asepsis, and a knowledge of surgical pathology. He asks, When did anaesthesia first see the light of day? and answers the question with the names of "Morton and Wells, two provincial Americans, and Sir J. Y. Simpson." "Antiseptic surgery, or its offspring, the modern aseptic surgery, had its birthplace in Glasgow, where Professor Lister (now Lord Lister) was professor of surgery." As to surgical pathology, the author points out how much it owes to a German provincial doctor, Robert Koch.

The author concludes, after lamenting the fact that the country of Jenner should be the first to cast discredit on his immortal work, as follows:

"Before closing this address I should like to say a few words on two thoughts that have struck me during its preparation—namely, the treatment that has often been doled out by the public, and even by members of our own profession, to those who have suggested some new thing, and the immense thanks the public owe to men whose names never appear on the roll of fame. Wells, who first tried ether in 1846, died in prison in New York, and Morton died in poverty, stricken with apoplexy. Sir J. Y. Simpson had to suffer an amount of slander and attacks of all kinds when he introduced chloroform that would have overwhelmed any ordinary man, and one can scarcely conceive that it is not fifty years ago that Spencer Wells was greeted at a London medical and surgical society with shouts of 'Down with the belly rippers.' Since then belly ripping has become quite a popular operation. One is reminded of Heine's words in an introduction to an edition of *Don Quixote*. He says: 'I used formerly to suppose that the laughable character of Quixotry lay in the fact that the noble knight was led to recall to life a long-buried past, and that his poor limbs, or rather his back, came

into painful collision with the actualities of the present. Alas! I have learned since then that it is just as thankless a piece of folly to try to bring the future prematurely into the present, and that any such antagonism to the substantial interests of the day is mounted on an exceedingly sorry nag, and is provided with very rusty armor and a body as easily shattered. A wiseacre will shake his head over one form of Quixotry as much as over the other.* Many a man has learned the truth of these words by bitter experience. The courage which is needed by the pioneers in surgery, more so than by those in medicine, is much greater than the public know. In fact, I think it needs more courage, and that of a higher stamp, to go dead against authority and one's professional brethren than to take part in war. The amount of work which has been done and the number of lives which have been saved by general practitioners is not recorded on the tablets of fame, and one may call them the lost legion of medicine."

Poisonously Pure Water.—The *Medical Register* for February 15th has the following editorial:

"No more startling proposition could well be conceived than the fact, which has long been known to physiologists, that the drinking of chemically pure water—i. e., water containing no dissolved salts or gases—is actually poisonous to the animal organism. The subject is fully discussed by Hans Koeppé in the *Deutsche medicinische Wochenschrift* for September 29, 1898. The purity of water is determined by testing its electric conductivity, and it is found that it is almost impossible to secure it absolutely pure. According to this writer, ordinary spring water has a conductivity of five hundred to six hundred or more on the scale employed, while commercial distilled water has a conductivity of over forty-nine. It is exceedingly difficult to prepare water of less than 2.13. Distilled water is an active protoplasmic poison, due to its property of extracting salts from animal tissues and causing them to swell up by imbibition. When taken into the stomach, it causes a swelling of the gastric epithelium, which is followed by desquamation and the production of a catarrhal inflammation. The practice of washing out the stomach with distilled water is condemned, but were it possible to obtain a really pure water the procedure would be even more injurious. The remarkable fact is brought out that there occur in Nature waters purer than ordinary distilled water. Such, it is asserted, is the water from clear natural ice, and it is to this fact that the gastritis produced by giving patients 'ice pills' to allay nausea is said to be attributable. In the guidebooks it is customary to warn tourists—against quenching their thirst with melted snow and the ice of glaciers. It has been supposed that the danger lay in the temperature of the water from these sources, but, according to Dr. Koeppé, its great purity is the cause of its injurious effects. Melted artificial ice is said to be less harmful. In practical proof of the poisonous qualities of pure water, the writer cites the instance of a spring at Gastein which has for centuries been known as the *Gitterthurnen*, or 'poison spring.' All chemical analyses of this water—and hundreds have been made—have failed to show the slightest trace of any injurious substance, yet it has well merited the name it so long has borne. It now appears that its poisonous qualities are due to its extreme purity! Its electric conductivity is only 3.12, far less than that of ordinary distilled water.

"In view of the facts brought out in the article re-

ferred to, a most pertinent question suggests itself: Within recent years the recognition of the danger lurking in water obtained from natural sources has led to the rather extensive introduction of distilled water for table use, and domestic stills are widely advertised in both medical and lay journals. Now it seems as if the use of such water, while avoiding the danger of imbibing disease germs, exposes the drinker to the equally undesirable alternative of consuming an actual poison. Practically, however, where such water is taken at mealtime, it would, we imagine, be free from danger, as it would at once be mixed in the stomach with food rich in salts. For use at other times it would be a simple matter to add to it a sufficient amount of saline material, and, judging from the published analyses of some celebrated 'mineral waters,' the drinking of which is at least not injurious, this addition need be very insignificant in amount."

Commenting on Koeppé's conclusions, the *Druggist's Circular* for March adds that "any one who has had occasion to wash his eye with the ordinary water knows that the operation is disagreeable, a certain degree of irritability being developed; and if he has also performed the same operation with the same water after adding thereto enough common salt to impart a distinct taste to the liquid, he knows that in the latter case there is little or no disagreeable sensation. That this fact has a bearing on the question at issue seems plain enough."

The Teaching of Physiology in Public Schools.—We have had a good deal to say upon the enforced teaching of so-called physiology in public schools as a mere matter of propagandism among children of the fads of innumerable cranks. The following letter by Mr. S. W. Williston, of the University of Kansas, published in *Science* for January 20th, will give some sort of idea of the value of such "physiology" from the point of view of valuable information:

"At the last biennial session of the Legislature of Kansas there was passed what is known as the State uniform text-book law. A commission was appointed whose duty it was to select the text-books of all grades used in the public schools of the State, which were to be furnished at a stipulated price to all pupils. No other texts than the one selected may be used by any school under pain of severe penalties. The law has now been in force for two years and these books are being used by several hundred thousand pupils. So far as I can learn, specialists or experts were not consulted in the choice of the texts. Wide latitude was given to the commission, the one important stipulation being that the books should be cheap! Protests have been made, but in vain.

The books must be used in every case where prior contracts are not in force. Let us examine the wisdom of the Kansas Solons in one case; I am told that others are like it.

"The text in physiology used in all grammar grades is one by a C. L. Hoxie, whoever he may be. As he is the author of text-books in physics, doubtless his name will be familiar to the physicists of the country. The work had the benefit of revision by two high school teachers of St. Louis. The part of the book on the revision ought certainly to elevate them from obscurity.

"We can sympathize, therefore, with the satisfactory statement by the author that 'it is evident that a thorough knowledge of physiology on a scientific basis can scarcely be estimated. If one has a knowledge of physiology will keep him so. I can be sure the same

knowledge will enable him to regain that priceless treasure—good health.' One must suspect that the author is a confirmed invalid! His definition of physiology is certainly unique:

"Physiology proper naturally divides itself into three departments—anatomy, physiology, and hygiene.' 'Bones, like all other organic structures, consist of cells; the cells are more or less of a hexagonal form.' He seems especially hazy about the lymphatic system: 'The lymphatics perform the office of absorption, chiefly in the skin.' At one time he has the lymph 'poured into the blood through the thoracic duct into the *vana cava* in the neck,' but farther on he modifies this by saying that the lacteals 'terminate in two ducts, which open into the large veins, and finally into the heart,' one on the right side and the other on the left side of the chest! 'The liver performs the double office of separating impurities from the blood and secreting bile.' The 'bile acts as a solvent of the fatty portions of food,' while we are informed that 'fat is an oily concrete substance, composed of stearine and elaine!' One of the chief functions of the saliva is to 'quench thirst,' and the 'epiglottis serves to decaden sound!' Among other 'important facts' the author says that the 'heart of quadrupeds lies in the middle line, and not to the left, as in man.' 'All reptiles have two auricles and one ventricle.' From the fact 'that coagulation is greater in the lower animals' he derives the very interesting conclusion that 'this seems to be a wise provision, since these animals can not stop a flow of blood from a wound by artificial means.'

"But enough. These few examples are chosen almost at random. The book contains more poor English, wild and loose statements of fact, errors, and absurdities than I ever saw before in a text-book of modern times. One might be amused at such stuff, published as 'science,' were it not that tens of thousands of children in this State are compelled to learn it, usually taught by teachers whose ignorance of the subject is greater than that shown by the author himself.

"Everywhere that a moral can be lugged in by the ears or tail the baneful effects of the poison alcohol are urged. Can such a book be expected to serve any useful purpose in teaching the principles of temperance?

"And this is what politics may do for science in the public schools!"

The Germicidal Properties of Blood Serum.—Dr. Franklin Warren White thus sums up his paper based upon a series of experiments conducted in the pathological laboratory of the Massachusetts General Hospital, which experiments are recorded in detail in the *Boston Medical and Surgical Journal* for February 23d:

"1. Human blood serum differs greatly in its germicidal action upon various kinds of bacteria. 2. Our experiments indicate that normal human blood serum is not actively germicidal for the *Staphylococcus pyogenes aureus* or the *Streptococcus pyogenes*. 3. Human blood serum does not lose its germicidal power for typhoid and colon bacilli, even in the late stages of chronic wasting disease. 4. Human blood serum in fatal disease occasionally loses part of its germicidal power for the colon bacillus shortly before death, but more frequently retains the germicidal power for this bacillus for several hours after death. 5. A weakening of germicidal power of the blood serum shortly before death undoubtedly favors an agonal invasion of the body by the colon bacillus."

Death from a Tooth in the Left Bronchus.—Dr. James S. Warrack (*British Medical Journal*, February 18th) records the case of a woman twenty-six years of age who drew in by a forced inspiration a tooth which had just been extracted under gas. Cyanosis, dyspnea, cough, etc., followed, and she had a sensation as of something fixed inside the chest. Complete functional obliteration of the left lung, with exception of some tubular breathing accompanied by a few moist râles at the apex, ensued. Hectic fever set in, and thirteen days after the accident there were marked signs of gangrene of the left lung. She died three days later. At the autopsy the missing tooth was found tightly wedged in the left bronchus, point downward and crown upward, thus acting apparently as a "ball valve." There was no bronchiole given off above the site of the tooth, so that entire obstruction ensued. The whole lung was gangrenous. The right lung was congested and oedematous, with beginning consolidation at the base.

Chancre of the Tonsil.—Professor Dieulafoy (*Bulletin de laryngologie, d'otologie et de rhinologie*, December 31, 1898) concludes a paper on this subject as follows: 1. Chancre of the tonsil is of frequent occurrence, polymorphous in character, and indured with manifold aspects; it is sometimes accompanied by herpes. 2. At times it simulates acute amygdalitis. The analogy between chancre of the tonsil and acute amygdalitis is all the greater from the fact that the symptoms are nearly identical. Sore throat even to the extent of accentuated dysphagia, rigors, fever, and extreme lassitude are symptoms common to both diseases. 3. Whatever be the appearance of chancre of the tonsil, whether it presents the appearance of a large follicular amygdalitis, is erosive, ulcerative, vegetating, diphtheroid, whether it is accompanied or not by rigors, fever, malaise, etc., symptoms not noticed as occurring in chancres of other regions, there are three signs which justify a diagnosis of chancre of the tonsil. These three signs are: (a) the unilateral nature of the lesion; (b) the induration of the tonsil; and (c) the presence of the characteristic glandular induration. In face of a lesion of the tonsil which appears suspicious—eroded, excrecent, or ulcerated—in face of an acute amygdalitis whose characters are any way unusual, we should always think of a syphilitic chancre of the tonsil if we wish to avoid a serious error of diagnosis. 4. The diagnosis is definitely confirmed by the appearance of the roseola and mucous syphilides.

The Theory of the Action of Lysins.—According to Dr. Carl Fisch (*St. Louis Medical Gazette*, February), P. Ehrlich and F. Morgenroth (*Berliner klinische Wochenschrift*, 1889, No. 1) say that, as is well known, the so-called Pfeiffer's phenomenon consists in the fact that cholera or typhoid germs, when introduced into the peritoneal cavity of animals, immunized against the respective infections, are immediately agglutinated and very soon transformed into minute granular bodies, which become a prey to the phagocytes or otherwise disappear. The same effect is obtained when the germs are injected into fresh animals, if some immune serum is added to them. *In vitro*, too, this dissolution of the bacteria can be observed, provided that the serum is quite fresh. Pfeiffer's explanation is this: The bactericidal substances in an immune serum are, as a rule, in an inactive condition, and need for the displaying of their potency a certain something that makes them

active and that is contained in the fresh serum and fresh body juices. Pfeiffer conceived the idea of comparing this process with digestion. Later, Bordet reported experiments with the blood of guinea-pigs treated with rabbit's blood, which had the property of dissolving the red blood-corpuscles of rabbits, a property not possessed by normal guinea-pig blood.

The author of this article utilized the blood of a goat, which had been treated for some time with blood serum of wethers, for a series of exceedingly fascinating experiments. This serum dissolved rapidly the erythrocytes of wethers' blood. Heated to 50° C. for half an hour, it lost this faculty and became inactive, but was rendered active again by the addition of a little fresh serum (from goat or wether). It was seen that this hemolysis, too, was due to the action of two substances, the one called "immune body," the other called "addiment" (addition). In accordance with Ehrlich's toxine-antitoxine theory we must conclude that the immune body dissolved in the goat's serum was being combined with the red corpuscles of the wether's serum. A number of experiments, to enter into which would lead too far here, made to establish this proposition showed absolutely positive results and made it clear that the immune body possessed a haptophorous group, which bound it to the wether's erythrocytes. Similarly it could be demonstrated that the "addiment" had no affinity whatsoever to the red cells, and did not combine with them under any conditions. Further investigation finally led to the assumption that the immune body contained two different haptophorous groups; one, which had a very great affinity to the corresponding haptophorous group of the red corpuscle, and another one of very slight chemical energy, which was able to take hold of the addiment present in the serum.

Since it is possible to demonstrate the same conditions in the construction of some enzymes (chymosin), and since the bacteriolysis as well as the hemolysis remind one very strongly of digestive processes, we are justified in concluding that the addiment is a digestive enzyme. We know that digestive ferments are normally present in any serum; owing to their slight amount they can not exert any effect, which, however, it becomes possible for them to do when, by the action of an immune body, they are brought into direct contact with a bacterium or an erythrocyte. The question, how many different ferments we ought to assume, is open, yet it would be sufficient to assume only one, while the number of the different immune bodies may be endless.

By looking at the phenomena described from this point of view the very obscure formation of lysins or bacteriolytic substances is at once transparent. It is nothing else but another form of "seithenketten" (lateral groups) production; while for the binding and assimilating of the comparatively small toxine molecule one haptophorous group (the antitoxine *seithenketten*) is sufficient, the conditions are different whenever large protein molecules or even whole cells (bacteria, red corpuscles) are to be digested (to be assimilated, to be made innocuous, etc. all these different expressions mean the same thing). These bodies as such are unavailable for the use of the body cells on account of their size; they must be first split up by fermentative processes. It is a very ingenious method, therefore, that the "lascos" of the protoplasm (the mucous bodies, etc.) at the same time are lascous ferment molecules, bringing them in intimate relation with the prey to prepare it for the final use of the protoplasm. It is

a wide view, again, that opens up before us through Ehrlich's genius; a hitherto perfectly inaccessible territory has been opened by it for cultivation.

The Uses of Apomorphine.—Dr. G. B. Malone (*Memphis Medical Monthly*, January) reports the efficient use of apomorphine in spasmodic asthma, the dose being one twentieth of a grain *per os*; in hysterical convulsions, one tenth of a grain hypodermically; in the convulsions of childhood, one twentieth of a grain being given to a child two years and a half old; and finally, in puerperal eclampsia, using an initial dose of one tenth of a grain.

The Relation between Chronic Appendicular Inflammation and Movable Right Kidney.—Dr. George M. Edelblom (*Post-graduate*, February) thus sums up his conclusions on this subject:

"Chronic appendicitis, as proved by the writer's clinical and operative work, is present in from eighty to ninety per cent. of women with *symptom-producing* movable right kidney. This frequency constitutes chronic appendicitis one of the chief, if not *the* chief, symptom of movable kidney. Chronic appendicitis, by reason of its frequency, the protracted suffering and serious impairment of health which it entails, and the dangerous possibilities of implanted acute attacks of appendicitis, may be considered the most important complication of movable right kidney. The writer's statistics show that twenty per cent. of all women have movable kidney or kidneys; that four per cent. of all women have *symptom-producing* movable kidney or kidneys; that four per cent. of all women have appendicitis; that, while three and a half per cent. of all women have both *symptom-producing* movable kidney and appendicitis, only one half per cent. of all women have appendicitis and well-anchored kidneys. The startling nature and importance of the conclusions to be drawn from these statistics does not invalidate the latter. Satisfactory investigation of the relations of movable kidney and appendicitis became possible only after the discovery and elaboration of the writer's method of palpation of the vermiform appendix. It remains impossible to those not practically familiar with the method. Chronic appendicitis may be the *only* symptom of movable right kidney. Some of the symptoms commonly ascribed to movable kidney are often in reality due to the concomitant appendicitis. The relations existing between movable *right* kidney and chronic appendicitis are those of cause and effect, for reasons detailed in the paper. A movable *left* kidney never produces appendicitis. Movable *right* kidney probably produces chronic appendicitis by indirect pressure upon the superior mesenteric vein, the return circulation of the appendix being hampered by compression of the vein between the head of the pancreas and the superior mesenteric artery. Appendicitis associated with movable kidney has a tendency to resolution or spontaneous cure, with the formation of a normal appendix, while the same is not true of movable. The only reason for this is that, under these conditions, is by slow process and in a small percentage. In twelve of the writer's cases, the movable right kidney and appendicitis were cured by the operation, only ended in resolution of the appendix. In twenty cases, after right or bilateral nephrectomy, the movable kidney attention to the appendix. Resolved spontaneously after right nephrectomy, but the expected cure occurred, which the associated chronic appendicitis was of comparatively recent origin. In a majority of cases, even of asso-

ciated movable right kidney and chronic appendicitis will either nephropexy alone, or appendectomy alone, meet all the indications. The majority of patients require both operations to restore them to full health. Both operations, right nephropexy and appendectomy, may be simultaneously performed through one and the same lumbar incision extending along the outer margin of the erector spinae muscle from the twelfth rib to the crest of the ilium."

A Hydatid Cyst of the Parotid.—M. Morestin (*Gazette hebdomadaire de médecine et de chirurgie*, February 16th) recently showed to the French Anatomical Society a hydatid cyst of the parotid which he had removed from a woman fifty years of age. The clinical evidence was that of a mixed tumor, but the removal of the tumor demonstrated its real nature.

Discharge of Large Vesical Calculus without Pain.—Dr. H. B. Stewart (*Georgia Journal of Medicine and Surgery*, February; *Virginia Medical Semi-monthly*, February 24th) reports the spontaneous expulsion of a stone weighing two hundred and twenty grains from the bladder of a white lady, aged seventy-six years, without any pain being complained of. The only trouble she experienced was a frequent desire to be over the chamber for about one week beforehand. The doctor has the stone in his possession. It measures an inch and three quarters in length and an inch and a half in circumference.

Acetanilide in Surgery.—Dr. M. D. Schmalhorst, of St. Louis, writes to us as follows: "At a boiler explosion two boys received numerous minor injuries, besides two very severe ones. On one there was a six-inch scalp wound, with fracture and depression. Hair, straw, and all sorts of dirt were carried down and pinched between the bones. The skull had to be removed to the extent of two inches by two inches and a half in diameter. The scalp wound was very ragged and turned back on each side for two inches. A branch of the meningeal gave considerable trouble. Some gauze was used here, packed against the bleeding point. Otherwise acetanilide was the dressing. The whole wound was kept literally stuffed full, about two ounces being used at each dressing. The result was all that could be hoped for.

"A compound, comminuted fracture of the leg came out most beautifully with the same dressing.

"I have used it exclusively for three years. It is very cheap, it is non-toxic, and it can and should be used bountifully to get its absorptive qualities. It will clear up an infected wound quicker than anything I have ever used either in hospital or in private work."

What is Fame?—The *Gazette médicale de Paris* for February 14th speaks of Dr. S. Weir Mitchell as "Dr. Weir Mitchell" and "Dr. Weir Michel," and of one of his stories as entitled "*Hugh Wynne*."

The Western Ophthalmological, Otological, and Laryngological Association. At the annual meeting, held in New Orleans on February 10th and 11th, the following officers were elected for the ensuing year: President, Dr. William Schipperell, of New Orleans; vice-president, Dr. M. A. Goddard, of St. Louis, and Dr. H. V. Wurdemann, of Milwaukee; secretary, Dr. F. C. Ewing, of St. Louis; and treasurer, Dr. W. L. Dayton, of Lincoln, Nebraska. The new members elected were as follow: Dr. J. A. Caldwell, of McKinney,

Texas; Dr. O. Joachim, of New Orleans; Dr. W. H. Baldinger, of Galveston; Dr. J. S. Mott, of Kansas City; Dr. J. S. Lichtenberg, of Kansas City; Dr. J. W. Bettingen, of St. Paul; Dr. J. W. Chamberlin, of St. Paul; Dr. H. M. Starkey, of Chicago; Dr. R. Brunson, of Hot Springs, Arkansas; Dr. Max Thorne, of Cincinnati; Dr. J. W. Scales, of Pine Bluff, Arkansas; Dr. E. M. Singleton, of Marshalltown, Iowa; and Dr. F. C. Ewing. The following names were added to the list of honorary members: Dr. George E. Stevens, of New York; Dr. St. Clair Thompson, of London; Dr. R. Coen, of Vienna; Dr. E. J. Moure, of Bordeaux; Dr. J. Sendziak, of Warsaw; Dr. Marcel Natier, of Paris; Dr. C. Ziem, of Dantsic; and Dr. A. A. Guye, of Amsterdam.

The National Guard of the State of Pennsylvania.—We learn from the *Medical Bulletin* that its editor, Dr. John V. Shoemaker, has been appointed surgeon-general of the guard.

A Lawyer on Medical Expert Testimony.—Mr. Henry Wollman, of the Kansas City Bar, recently delivered a notable address before the Kansas City Academy of Medicine. In the course of his remarks he said:

"The most important thing for a witness is to impress the judge and jury with his absolute sobriety of thought, his earnestness of purpose, and his unquestioned sincerity. The average physician permits himself, on the witness stand, to be drawn quickly into a fencing match with shrewd counsel, and, while it is true that the doctor often gets away with the lawyer, because he knows more about what he is talking about than the lawyer, and is often able to crack an exceedingly biting, bitter, and galling joke at the lawyer's expense, still every time he does it he has weakened himself with the jury. They regard him as a sharp man, and, as a rule, people do not readily trust sharp men."

"When the temptation is on you to crack a joke on the witness stand, remember that, as a rule, we laugh at jesters when that becomes their predominant characteristic, but we do not have any great amount of faith in them. Take the clown in the circus, take the comedian on the vaudeville stage; he makes you forget your troubles, your trials, and your tribulations; he makes your very sides split with laughter, but you don't care to associate with him. You rather pity him."

"Naturally and necessarily lawyers understand human nature thoroughly. Next to their knowledge of the law, their knowledge of human nature is their most important stock in trade, and they know that if they can provoke a doctor into saying sarcastic, sharp, savage things, or cracking jokes, they have robbed his testimony of its most important qualities, and have destroyed its influence with the jury."

"The witness, testifying as an expert, must be cautious, careful, serious—old-fashioned, you might say—about what he says, and he will carry conviction. Let the jury think you are a little slow, if they only think you are honest and sincere and know what you are talking about.

"The next objection that I would urge to a great deal of testimony is the unfortunately vain desire of many of the younger professional men to show off. They allow their desire for ostentation to get away with them. They answer questions by delivering essays, when a short 'yes' or 'no' would do just as well. They use big words; they endeavor in any and every way to impress upon the jury that they are the real thing, and

erful within and of themselves that the Golden Rule is recognized by even their worst member as an absolute necessity, if he wishes to stay in. Of course, you can not be as powerful as they are, because a man can practise medicine without being a member of a recognized medical society, but you can do much more than you now believe."

"Whatever legal measures are passed by legislatures will be evaded as easily as our present method of having the court appoint an examiner. The remedies must come from within societies like yours. Let me suggest this—that each of your medical societies appoint five or six members who shall act as experts, say, for a term of six months, and none of whom shall ever see anybody with a view to becoming an expert witness, except when he is acting as a member of your committee, and then say that three members of the committee shall go together to make the examination. Require the party who wishes the expert testimony to deposit a reasonable sum with your treasurer, and let that money be the sole compensation of the committee for making the examination, except what the law allows them as ordinary witness fees, and then let every other member of your societies refuse positively and unequivocally to do anything with a view to becoming an expert witness. The parties will then be driven, if they want eminent experts, whose worth will be recognized, to get them through your societies. The party who applies to you for the services of your experts must be exceedingly sure of his case, for your committee, being absolutely fair and impartial, will not have any reason or motive for favoring him, and will not do so. The man pays just as much for an unfavorable as for a favorable decision. The committee will have nothing to gain by going on the stand. Their pride and honor can be relied upon not to turn a man down just to get out of going on the witness stand. A man will always be sure he can get the best quality of expert testimony in a straight case. In a crooked case he will be unable to buy it from physicians of recognized standing.

"The courts undoubtedly, when application is made to them to appoint medical experts to make a physical examination of a witness, under our present practice, would recognize your committee. The courts fully recognize bar associations, although seldom incorporated, and when a man applies for admission to the bar the court appoints the examining committee for the bar association to conduct the examination. I have never known of a case where the court has admitted a man whom the bar association committee reported unfavorably, or refused to admit one whom this committee reported favorably. So I think that there will be no trouble in getting all the courts to say that they will never appoint any physician to conduct these examinations unless he is a member of the regular committee of a recognized medical society, and, as this matter as to who shall be appointed lies in the discretion of the court, the courts could legally make and enforce such a rule. Even if the courts didn't recognize your committees, as I am quite sure they will, still, they couldn't force any member outside of your committee to look at a case with a view to becoming a witness.

"As a business proposition, it has always seemed to me that a busy physician really lost money by becoming an expert witness; that is, the length of time that he put in in visiting the case, consulting the lawyers, waiting around the court room, and testifying, did not make it at all profitable for him; so that I think there will be

no loss of money to you by your failure to become expert witnesses, and it seems to me that the proposition I have just advanced, if your societies would be rigid, and your members would recognize their authority, as they undoubtedly will, would be a great cure for the evil that is certainly disgracing your profession."

"Now, shall it be said that a learned profession like yours, composed of cultured, educated, refined gentlemen, in this age of commercialization, has become commercialized to the extent that it itself has become the object of barter and its members the subjects of purchase and of sale? No. Let it be the constant aim of every member of the profession to stop this thing, and to make it impossible for any one to get any physician to go upon the witness stand, not as the impartial, judicial narrator of what, because of his learning and skill, he is able to see where the eyes of the less experienced and more unlearned can discern nothing, but as the paid, partial, and biased advocate of one, who thus puts a price upon his honor."

Abdominal Section under Cocaine Anæsthesia.—

Dr. Hunter Robb (*Cleveland Medical Gazette*, February) records the following case, which is of interest for several reasons. Quite an extensive operation was performed under cocaine anæsthesia; the abdomen was opened, the adherent retroverted uterus was released, brought forward, and stitched to the abdominal wall. As a result the patient was entirely relieved of the local symptoms—namely, the backache and pelvic discomfort of which she had complained for over a year. At the same time her general condition improved, the cardiac symptoms became less pronounced, and the goitre diminished considerably in size.

In order to relieve the pelvic condition it was decided to release the adherent uterus. The operation was performed on October 10, 1898, at Lakeside Hospital. Owing to the general condition of the patient, who suffered from cardiac trouble associated with goitre, it was thought better to employ local anæsthesia. Eight minims of a five-per-cent. solution of cocaine having been injected beneath the skin, an incision was made in the median line down to the muscle sheath. Eight minims more were injected at different points along the median line into the muscular structures, and the incision was then carried into the peritoneal cavity. The adhesions binding the uterus down to the rectum were separated without any apparent discomfort to the patient. It is to be noted, however, that even slight traction upon the ovaries seemed to produce considerable pain. The uterus was brought forward and stitched according to the ordinary suspension method. The peritoneum was closed by means of a continuous catgut suture; chromicized catgut being used for the fascia and a continuous subcutaneous catgut suture for the skin incision. The patient made an uninterrupted convalescence and left the hospital November 8, 1898, twenty-nine days after her admission. At the time of her discharge she was entirely free from backache and from all pelvic discomfort. The circumference of the goitre on October 20th was thirty-three centimetres (thirteen inches) and on October 25th 31.8 centimetres (twelve inches and a half). When she left the hospital on November 8th, it measured twelve inches, a reduction of one inch in twenty-nine days. The pulse at the time of her admission varied between 106 and 150. After the operation the rate gradually diminished and at the time of her discharge it averaged about 101.

Original Communications.

ON A POLYMORPHOUS CEREBRAL TUMOR

(ALVEOLAR GLIOMA?)

CONTAINING TUBERCLES AND TUBERCLE BACILLI

By CLARIBEL CONE, M. D.,

PROFESSOR OF PATHOLOGY, WOMAN'S MEDICAL COLLEGE, BALTIMORE

[From the Pathological Laboratory of the Johns Hopkins University and Hospital.]

(Continued from page 336.)

THE case about to be reported occurred in the service of Dr. Cohen, of Bay View Asylum, and was brought to the pathological laboratory of the Johns Hopkins University by Dr. Henry J. Berkley, to whom I am indebted for the brief clinical notes and the autopsy record.

Clinical History.—X. Y., aged approximately sixty-five years, was admitted to the W. F. H., Bay View, November, 1897, and died three days after. When admitted the woman had full consciousness, but was totally unable to enunciate, nor was there any history that accompanied her. She gradually became comatose, and died in the coma.

Autopsy Record.—The autopsy was negative, except as regards the brain. In the left temporo-sphenoidal lobe was found a tumor, deeply situated (Fig. 1). It was about three by four centimetres in size, and had an area of necrotic tissue surrounding it about half a centimetre in width. The tumor occupied about two thirds of the left temporo-sphenoidal lobe, corresponding with the second, the lower portion of the first, and the upper portion of the third temporal convolutions.

FIG. 1.—Diagram of brain with tumor in situ.

It extended inward, pressing upon the convolutions of the island of Reil. Only at one point did the tumor protrude the surface. The necrotic area was more appreciable toward the upper portion of the lobe toward the interior region. There were no metastases in the brain or other organs, nor was there any evidence of tuberculous.

Naked eye.—*Appearance of Alcohol hardened Specimen.*—The tumor is an irregularly lobulated mass of smooth surface, and covered by a membrane from which project numerous filamentous processes. The

color is grayish white, its consistence is firm and elastic. On section through the mass the cut surface presents an opaque yellowish-white color, dotted and streaked with fine lines of translucent gray (Fig. 2). This gray substance finds a marked development in the centre, where it forms a trabeculated network. Within the gray substance are several small circumscribed areas of necrosis (Fig. 2, N). At one point the tissue is

FIG. 2.—Cross section of tumor after alcohol hardening. Enlarged four times. S, C, area resembling simple carcinoma; C, C, area resembling carcinoma with large branching alveoli; S, area resembling simple carcinoma; E, G, and G, areas resembling glioma; E, area resembling endothelioma; N, area of necrosis.

soft and spongelike, despite alcohol hardening. From this spongelike tissue the capsule can be removed with moderate ease, but at other points it is firmly adherent.

Histological Examination.—Serial sections were made, and many slides were stained by the following method: 1. Haematoxylin and eosin. 2. Mallory's phosphotungstic-acid-haematoxylin. 3. Mallory's phosphomolybdic-acid-haematoxylin. 4. Van Gieson's picric-acid-fuchsin. 5. Weigert's iron stain. 6. Gabbet's carbol-fuchsin. Unstained specimens were also examined in glycerine. The sections stained with haematoxylin and eosin are most satisfactory as presenting the greatest variety of lesions. The following description, however, is the result of the examination of many sections stained by the different methods.

With low magnification the capsule extending completely around the tumor, dipping down between its convolutions, and sending processes into the mass, whose structure is thus broken up into more or less imperfect lobes. The capsule is closely connected with the tumor in one place, quite separated in another, but for the most part it is very lax. In some places it is more or less honeycombed, and is completely fibrillated at other points. Here and there it tapers off to a minute strand. At one point it is split in the center, and contains a few strands of lamellar tissue.

Of the numerous small nodules scattered throughout the periphery of the tumor, only a few are seen. They have the appearance of small, rounded, or oval, necrotic foci.

The tumor is composed of two main parts. The outer part is a thin, translucent, yellowish-white, and the type of the tumor is the same. The inner part is a thick, opaque, yellowish-white, and the type of the tumor is the same.

type of growth to another. Where the lobular character is lost these transitions are most marked.

Of the lobules, the structure in some places resembles that of simple medullary carcinoma (Fig. 3). It is made up of alveoli containing many hundred cells and surrounded by a very cellular stroma, which is continuous with the processes extending in from the

times they are lined by high cylindrical cells, at other times by low cuboidal or polyedral forms.

One nodule imbedded in the tumor is made up of a sarcomalike tissue containing giant cells (Fig. 5, *a*). It is diffusely cellular in the centre, but this diffuse cellular growth can be traced as a transition from alveoli in the periphery of the nodule.

FIG. 3.—Alveoli and fine simple medullary carcinoma. Hematoxylin and eosin stain. Zeiss objective A A, ocular No. 3.

capable. The alveolar structure is made conspicuous because of the difference in the character of cells in alveoli and stroma. In some places this structure is emphasized by a distinct peripheral border of high cylindrical cells.

In other lobules the type of growth is that of tubular carcinoma or of adenoma (Fig. 4, *a*). The tubules sometimes contain a lumen, at others not. Some-

This nodule is partly surrounded by a wedge of tissue, made up of large branching alveoli which are lined by close-set cylindrical cells and are distinctly marked out by a fibrillated stroma (Fig. 5, *b*).

Toward the centre of the specimen, where the lobular arrangement is lost, are numerous blood-vessels, each surrounded by a distinct collar of cells which extend inward as far as to the intact intima (Fig. 6). These

stand out conspicuously against a loose-meshed reticulum and give the impression of perithelial angiosarcoma or endothelioma. There are also vessels not so surrounded, and the cell groupings may extend away from the vessels into the tissues, where they become continuous with the tubular alveoli above described or resolve themselves into a diffuse cellular tissue.

with the cells, nor, indeed, do typical neuroglia cells occur.

Thus, of the many histological types of which this tumor is composed each one may be traced as a transition from some other. There are focal areas of necrosis and other features which can be best studied with greater magnification.

Fig. 1. *a*, Area resembling tubular carcinoma. *b*, blood vessel with red-stained endothelium. *c*, double row of cylindrical cells. H. & E. stain. Counterstain: blue. Magnification: $\times 100$. A, color No. 5.

In other areas there is a diffuse arrangement of small polyhedral cells mingled with highly refractive fibres. The high refraction is especially noted in unstained sections mounted in glycerin, and is sometimes seen in these sections stained with hematoxylin and eosin. This appearance is suggestive of fibrin fibres, and gives the impression of ghema formation. But at no time are the fibres found to be continuous.

Under the high power the tumor was found to be made up of fibrillated connective tissue arranged in parallel lamellae, between which were many small round cells. These cells extended in a row along the fibrous processes that divided the tumor lobules. Thence they extend into the interlobular stroma about the alveoli. They extend into the alveoli at times, producing a diffuse infiltration with tumor cells.

(Figs. 3 and 4). Accompanying the lymphoid cells are sometimes epithelioid cells, and an occasional giant cell with homogeneous protoplasm and peripheral arrangement of its nuclei.

These cells are sometimes grouped into discrete microscopic tubercles, which are mostly confined to the stroma, but at times involve the alveoli. When within

necrosis. Pyogenic cocci could not be found (Weigert's fibrin stain). Within the blood-vessels are many polymorphonuclear leucocytes and thrombi. When the thrombi completely plug the lumen they are often surrounded by circumscribed areas of necrosis at times of considerable extent. These necrotic areas show either the faint outline of the original tumor structure or a

FIG. 5. *a*, Areas resembling simple sarcoma; *b*, margin of large branching alveolus. Hematoxylin and eosin stain. Zeiss objective A X, ocular No. 5.

an alveolus the tubercles often include the tumor cells within their structure. By the use of Gabbet's carbol-fuchsin stain tubercle bacilli were demonstrated.

Infiltrating the tumor in places are also polymorphonuclear leucocytes. These are not numerous in the stroma. They accompany the small round cells in certain areas, and greatly predominate in others. Where they infiltrate the alveoli the alveolar structure is blurred. They are often associated with fibrin and

granular texture with peripheral radiation of epithelioid cells.

That portion of the capsule which under the low power appeared homogeneous and highly refractile is found with greater magnification to be made up of a fine meshwork of fibrils, including small round cells. It resembles embryonic brain tissue where stained with hematoxylin and eosin, but is found to contain fibrin where Weigert's fibrin stain is used. The loose-meshed

reticulum in the centre of the specimen is composed of oedematous fibrous (perhaps mucoid) tissue likewise infiltrated with fibrin and containing isolated tumor cells. The latter show different degrees of atrophy and various kinds of degeneration, for the most part fatty.

The individual tumor cells show many different forms. Where the structure conforms to the type of the simple medullary carcinoma the cells of the alveolus

carcinoma the cells are high cylindrical or low cuboidal. But when the tubules suffer from compression the lumen of the tubules is lost and the lining cells become small and polyedral or flat. The tubular texture therefore passes over into mere lines of cells, which soon break up until all appearance of organoid structure is lost.

The nodule which contains a carcinomalike periphery and sarcomalike centre shows every transition

FIG. 1. A carcinomatous nodulus. H. = Hematoxylin and eosin stain. Z = zone of transition.

also conform to the type, being large, most in form of a cylinder, and containing much protoplasm and large round or oval nuclei. When the periphery of the alveolus is polyedral or cuboidal cells the number of rows is reduced within the protoplasm at its base, and the stroma.

Where the structure of the tumor is of the

from the most common type of the tumor, the cells are high cylindrical or low cuboidal. But when the tubules suffer from compression the lumen of the tubules is lost and the lining cells become small and polyedral or flat. The tubular texture therefore passes over into mere lines of cells, which soon break up until all appearance of organoid structure is lost.

The giant cells of the tumor may be of any size and shape, but are usually many times larger than the average tumor cell. They contain one or several large nuclei or many small ones. The small nuclei are usually round and vesicular. The large nuclei are round, oval, or irregular in shape, and usually contain coarse chromatin granules which take a deep hematoxylin stain. Sometimes the nucleus is occupied by one or more hyaline-looking bodies, and the nucleolus itself may have undergone the hyaline change or may be distended with vacuoles or fat. Large budding nuclei and atypical nuclear figures, such as giant mitoses, multipolar mitoses, and forms showing karyorrhexis, are numerous. In the giant cells the nuclei are usually near the centre and are surrounded by a broad zone of granular protoplasm. But sometimes degeneration products distend the cell, push the nucleus to the periphery, and give the signet-ring effect.

The wedge of tumor tissue, made up of large branching alveoli, lies next to the last-mentioned nodule and contrasts sharply with it (Fig. 5, *b*). In the periphery of the alveolus the cells are uniformly high and cylindrical. In the interior they are small and polyedral.

In the centre of the tumor, where the structure resembles perithelial angiosarcoma, the collars of cells surrounding the blood-vessels are made up for the most part of groups of tubules bound together by connective tissue, and lying parallel with the long axis of the vessel or oblique to it. Like the simple tubules described above, the individual tubules of these perivascular collars possess a lining of cylindrical, cuboidal, or polyedral cells. They also lose their tubular character in places and surround the vessels as a diffuse proliferative growth. Sometimes single rows of high cylindrical cells sit upon the vessel walls, with their free ends turned outward and the nuclei located in the basal portion of the cells. Occasionally a double row of such cells is seen, always with the nuclear end toward the vessel wall (Fig. 4, *b*).

The protoplasm of the tumor cells is usually coarsely granular, but various forms of degeneration may cause it to appear hyaline and homogeneous; fatty, pale, and trabeculated; vacuolated, or distended with single large droplets of fat. Besides these, cellular inclusions often exist.

(To be concluded.)

A REMARKABLE CASE OF EPILEPSY IN WHICH FIVE HUNDRED AND NINETEEN SEIZURES OCCURRED IN FORTY-NINE HOURS. NOTES ON TREATMENT, DEATH, PATHOLOGICAL FINDINGS.

By WILLIAM P. SPRATLING, M.D.,
SUPERINTENDENT OF CRAIG COLONY, SONTEA, N. Y.

My object in reporting this case is to call attention to two facts already well known by every physician who is brought much in contact with epilepsy, and who, sooner or later, must be made to feel the weight of such facts too heavily. They are:

1. The remarkable obstinacy with which epileptic seizure manifests them elven in spite of all efforts known to the science and art of medicine to suppress them.
2. The complete failure, either of the naked eye or

of the highest objective of the microscope, to reveal anything in the brain, under post-mortem examination, that might be held accountable as causing the convulsions in a case even in which such convulsions had occurred hundreds of times and with great violence during so brief a period as forty-nine hours.

J. M., woman, aged twenty-two years, was admitted to the colony July 22, 1896. She developed epilepsy in infancy. Her attacks at first were of the *petit-mal* type, but later changed to the *grand-mal* type. On admission to the colony it was noted that her intelligence was of a low order, due to the destructive influence of the seizures operating since infancy. It was also noted when she was admitted that her attacks occurred once a day on an average, but after some months' treatment at the colony they were reduced to one half their former frequency, so that just prior to her death they averaged from fifteen to eighteen a month. She was employed in the laundry and did good work. Notwithstanding the frequency and severity of the seizures, she suffered no appreciable physical impairment, though it was noted that her mental faculties became constantly less acute.

She retired on the night of July 31, 1897, apparently as well as usual. Her regular attending medical officer was absent on vacation, and I was called to see her at one o'clock the following morning. She had just had three seizures, all severe in type.

Having learned by experience the usually fatal significance of *status epilepticus*, and having learned to regard such isolated groups of seizures or serial attacks as frequently being the forerunner of that fatal condition, I at once gave her a special preparation that is usually efficient in checking such manifestations. The preparation is as follows:

R Tinct. opii deod. ℥ v;
Potass. bromid. gr. xxx;
Chloral. hydrat. gr. xx;
Liq. morph. (U.S.) ℥ jss.

To be given as a single dose, and it was so given in this case.

It was effective. She had no further seizures until 6.40 o'clock the same morning, a period of nearly six hours. At that hour they recurred, and by 8.20 o'clock she had had seventeen more. A dose of the above was repeated, and again its action was good, checking the seizures until 4.25 o'clock the same afternoon. At that hour they recurred, when, for the third time, the special preparation was again administered. This time it had no effect whatever, as will be noted by the following record of seizures that occurred between that hour and 6.45 P. M. the same day, a nurse in constant attendance making a note of each seizure, its hour of occurrence, duration, and character: 1.25 P. M., 4.10 P. M., 4.45 P. M., 4.50 P. M., 4.55 P. M., 5 P. M., 5.10 P. M., 5.20 P. M., 5.25 P. M., 5.30 P. M., 5.45 P. M., 5.50 P. M., 5.55 P. M., 6 P. M., 6.05 P. M., 6.15 P. M., 6.20 P. M., 6.25 P. M., 6.30 P. M., 6.35 P. M.

And just here let me digress a moment from describing the further treatment of the case, to give the remarkable features of the fits themselves.

Their order of origin and progression was as absolute and as fixed as were the time periods that marked the intermission, the beginning and ending of each convulsion.

1. The first visible contraction, five hundred and nineteen times in succession, was the bending of the first

joint of the right thumb at right angles to the thumb (Fig. 2). (Fig. 1 shows hand and thumb in normal position.)

2. The second step in the order of progression was the drawing of the bent thumb into the palm of the hand (Fig. 3).

FIG. 1.

FIG. 2.

FIG. 3.

3. The third step in the order of progression was the bending of the four fingers, held still together, at the third joint at right angles to the palm of the hand (Fig. 4).

4. The fourth step in the order of progression was the imbedding of the ends of the four fingers in the palm of the hand over the contracted thumb (Fig. 5).

5. The fifth step in the order of progression was the bending of the now closed fist forward at right angles to the forearm (Fig. 6).

6. The sixth step in the order of progression was the bending of the hand and forearm upward in such a manner as to closely approximate the same to the upper arm.

Then the entire arm was drawn up and out at right angles to the body, the right side of the face contracted, and the head drawn to that side, while the right side of the body and the right leg were next involved.

Now comes an interesting point. As long as the patient was kept under profound chloroform narcosis, which was the case for nine consecutive hours out of the forty-nine the convulsions lasted, during which time she did not miss a seizure, the right side only participated in the convulsion; but when not under the chloroform the contractions, after attacking the right side, as above described, then passed rapidly to and involved the entire left side in a quick general spasm. And let me repeat the fact once more that this particular order of origin and invasion occurred five hundred and nineteen separate and distinct times, not varying in any way whatever; and that the periods between the seizures were markedly uniform, the intervals never less than ten and never longer than fifteen minutes in duration.

In the further treatment of the case the specific preparation was repeated again at 5.20 p. m., but with out effect. The lower bowel was then thoroughly cleaned by liberal douching and the same medicine administered by enema, but without effect. Half a grain of morphine sulphate was then hypodermically administered, but at the end of two hours it had produced no effect so far as could be seen.

At nine o'clock it was decided to resort to chloroform, and she was kept profoundly under its influence for two hours, the only result being that during the condition of narcosis the contractions did not extend to the left side, so at 11 p. m. its use was abandoned.

There was not at any time any cessation of the fits. The patient remained conscious between them until she had passed through about two hundred; and during the brief moments between seizures up to that time she was able to take small quantities of liquid nourishment.

In the meantime all known measures that might have some influence in checking the seizures were tried in succession, but none were effective. She had hot packs and cold packs; she had the most powerful sedatives and motor paralyzants, administered by mouth, by enema, and under the skin; the remedies by inhalation, chloroform and nitrite of amyl; the bandaging under tight compression of the entire right arm, with a rubber bandage, from the finger tips to the shoulder, as recommended by Trousseau in similar cases, and when the contractions begin in a single extremity; in short, all known drugs and forms of treatment that offered the slightest hope of relief were tried and repeated many times, but all to no avail.

Just after the one hundredth seizure she was bled from the left arm, but it did no good. The blood was saved, defibrinated, and sent to Dr. C. A. Herter for examination, but he was absent from home, and it did not reach him in a week, and in the meantime was spoiled.

After the two hundredth seizure it was decided to trephine. The head was shaved, scrubbed with soap and water, and the usual routine antiseptic precautions observed prior to such an operation, but it was not performed. Just as all arrangements were completed her temperature began to rise, and went by rapid strides up to 104°, 105°, 106°, and finally to 106.5° F. She became continuously unconscious, was unable to take any nourishment; the entire body was bathed in profuse perspiration, so much so that it was necessary to change the sheets every two hours. Her face became blue, cyanotic; breathing, labored, stertorous; hands and feet

FIG. 4.

FIG. 5.

FIG. 6.

cold, and the force of the contractions gradually became progressively less severe. As the doctor says that the decline in vitality was evident in this way—that is, in the loss of force of the contractions. Since the time of this case I have met another case very similar, in which originally the number of

two hundred occurred in one day, and I was able to measure the force of the contractions in the hand by placing a dynamometer in the same and gently holding it in place in such a way that all the force of the contraction was exerted on it. There was a difference of eight points between the right and left hands, and it is a singular fact that the power exerted by the morbid contraction of the muscles during a fit was much greater than could be produced by the patient at pleasure, after having fully recovered from the exhausting effects of the severe series of attacks. This is a measurable instance of superhuman force.

Reverting to the case in question, all operative interference was abandoned after this condition of affairs was established. And there is little more in detail to be said, except that once again chloroform was tried, and kept up this time seven hours, thereby, I am confident, prolonging her life to some extent, for immediately upon its withdrawal the attacks increased greatly in violence, and after shorter intervals, and she died after the five hundred and nineteenth seizure, all of which occurred within forty-nine hours.

The brain was removed four hours after death, great care being taken that it suffered no mutilation or the slightest injury of any kind. On inspection nothing abnormal was revealed, not even the blood-vessels of the coverings being engorged to any extent; in fact, the superficial aspect of the entire brain, as to color, was rather pale. Naturally the opposite was expected. The convolutions covering the right hand and thumb centres were especially studied, but with entirely negative results. Without cutting it in any way it was carefully packed and shipped the same day to Dr. Ira Van Gieson, director of the New York State Hospitals Pathological Institute, New York city.

It was injured in transit, a fact always to be regretted, and one that emphasizes the necessity for such an institution as the colony having on the premises the needed facilities for scientific work at such institution and by such institution. The blood drawn after the one hundredth seizure likewise was spoiled through shipment, being delayed so that it did not reach its destination until the eighth day after; and this again illustrates the above point.

Under date of February 4, 1898, Dr. Van Gieson reported on the cases as follows:

"I have gone over the J. M. case, but its preservation is so defective that I can give no report on it. I can find no changes that I dare exclude from artificial ones, which with the Nissl method of study are many and complex, and not as yet generally known. I have cut from the motor zone of the affected side, and can report no changes which in view of the preservation we might justifiably associate with the symptoms. I should have expected at least focal neuralgia (subcortical), mainly in the hand centre. But to show this we have to use some special method, such as Golgi's or the carminate of sodium in the staining, which, of course, alcohol hardening will not observe. So much nowadays depends upon the great variety of methods of hardening and staining,

which all have to be used in the same case, especially epilepsy, that it is the all-important and primary factor in the study of such cases.

"After all, no one has yet discovered the changes due to epilepsy, and we can hardly expect to find it on the spur of the moment to-day. All that have ever been found, after eight years' work at the thing, are evidences of *premature aging of the ganglion cells in the motor cortex*, and this I can not formulate dogmatically."

For his kindness in making this study, and his later interest in scientific matters in connection with the study of epilepsy, and in the building of the colony laboratory, I thank Dr. Van Gieson most heartily.

PRELIMINARY REPORT ON EXAMINATIONS OF THE URINE IN THE INSANE.

WITH A REPORT OF TWO HUNDRED AND TWO CASES.*

By EDWIN G. KLEIN, M.D.,

MEDICAL INTERNE, WILLARD STATE HOSPITAL.

DR. REGIS says: "The most important of the secretions in the insane, as it is in the physiological condition, is that of urine." Much has been written on this subject, and investigators seem to agree upon most points; yet wide differences of opinion exist as to the presence or absence of certain and important abnormal ingredients. Especially is this true of glucose. But before going into some of these it might be well to first consider the subject in a general way.

One of the most difficult things to ascertain in the insane is the amount of urine excreted in any given time. What these difficulties are are so well known that they need no repetition here. But with the assistance of several nurses, afforded me through the kindness of Dr. T. J. Currie and Dr. R. E. Doran, I was able to arrive at the following:

The average quantity passed in twenty-four hours, in one fourth of the above number, by male patients was, approximately, 1,125 c.c., and by females 1,020 c.c. These results at first seemed somewhat low, and the causes assigned were many. However, on referring to some late statistics given by Simon, the above figures are nearer normal than at first supposed. Dr. Simon gives from 1,000 to 1,200 c.c. for males, and from 900 to 1,000 c.c. for females, as being the normal daily amount in the United States; while in Germany and Austria, countries where much beer is drunk, he gives the daily average as being from 1,500 c.c. to 1,700 c.c. The corrected average specific gravity in the same number of cases was 1.019. The lowest was 1.005, occurring in a case of polyuria, and the highest was 1.035, and in which glucose was found. The reaction in the whole number was invariably acid.

* Read before the Willard State Hospital Medical Society, January 11, 1899.

Frequently, however, an apparent alkaline reaction was found, but in only one case—a case of cystitis—was this reaction permanent. An amphoteric reaction was seldom observed. There was nothing remarkable about the odor. Many of the specimens, however, especially those obtained from general paralytics, readily underwent decomposition and soon became foetid. The amount of total solids was, as a rule, under the normal. Urea varied with the specific gravity, as it does in all normal urines, but on the whole it was decreased.

Dr. Johnson Smyth (1) says that the urea is in excess in all cases except dementia. But a number of authorities consulted gainsay this. I might incidentally mention here a point in the diagnosis between a true epileptic paroxysm due to neoplasm and that of hysterical epilepsy, as observed by M. Gilles de la Tourette and M. Cathelineau in Charcot's clinic (2), which is: that in the true variety, due to new growth, there is always a notable increase in the fixed residues of urea and phosphates at the time of the paroxysm, while in the hysterical form there is a perceptible decrease in the same elements at the same time. Occasion was not afforded to observe this, but in the examinations which are at present contemplated, notes will be made.

Phosphates were somewhat decreased in almost all the excited patients, while in most of the depressed patients the reverse was true. From the studies of Mendel and Mairet (3), it appears that the phosphates, especially the earthy ones, are increased in the excited periods of insanity. Lombroso, Dr. McDowall (4), and Dr. Addison (5), whose observations, however, are not so recent, hold to the opposite view.

Oxalates in excess were observed in six of the depressed patients. The subject of phosphaturia and oxaluria is dwelt on at some length by Dr. Clouston in his recent excellent work (5a), and I think it might be well to quote a few of his remarks: "All writers on the urine," he says, "have noticed the hypochondriacal depression of mind, want of energy and originating power, and the irritability that so often go along with the presence of much oxalate of lime and phosphates in the urine.

"Dr. Prout (Prout, p. 176, second edition) thought that the mental state was probably the cause of these abnormal products in the urine.

"Golding Bird (G. Bird, pp. 350-307) says the persons affected with oxaluria are generally remarkably depressed in spirits, hypochondriacal, extremely nervous, painfully susceptible to external impressions, and, in many cases, labor under the impression that they are about to fall victims of consumption.

"The late Dr. Begbie showed that the nervous symptoms are apparently a result of the oxaluria, and disappear under the treatment which cures it.

"There is, on the other hand, no doubt of the fact that oxaluria may be found in a very great number of persons in good health. Lehman, Bence Jones, Gar-

rod, and many others, direct special attention to this fact."

Dr. Clouston concludes by saying: "I think there is scarcely enough evidence to show whether the condition of the urine is a cause or an effect of the brain state. But no matter which, treatment directed to the removal of the same seems to have a beneficial effect in my cases."

On the other hand, Dr. D. G. Stabley (6) reports having treated eleven cases in which oxaluria existed on admission, and only one patient was convalescent at the time of his writing. However this may be, yet the hint given by Dr. Clouston is well worthy of a good deal of attention. In the several cases of oxaluria previously mentioned, treatment was directed to the removal of the same. Two of the patients recovered their mental stability, or at least were able to leave the hospital. I do not wish it to be inferred that the oxalates were the cause of the melancholia or hypochondria, and that their removal brought about the recovery. But I do believe that the special treatment given in these cases, combined with the moral and tonic treatment, very possibly had some influence in hastening the much-hoped-for results.

The observation made by Dr. McDowall, that the chlorides are increased after an epileptic seizure, was noticed in three of the four cases examined. It was also noticed in one case of general paralysis following a convulsive attack.

Uric acid in excess was frequently observed in dementia, and several times in general paralysis. This is but in keeping with what one might expect in these conditions. Urates when in excess were usually associated with a dyspepsia.

Dr. Marro (7) says that he constantly found peptone in the urine of twenty general paralytics. The amount usually was very small—greater in cases following an acute course—and required as much as from eight hundred to a thousand cubic centimetres of urine to give Hofmeister's reaction. Dr. Marro quite concludes that the absence of peptone excludes general paralysis. Kippel (8) says that peptone is very frequently present in the second stage of this disease.

In twelve cases of general paralysis—all in the third stage—which I examined, peptone was present twice. I will state, however, that the tests applied were not very delicate, and that if they had been the findings might have come nearer to those obtained by Dr. Marro.

With regard to albumin, authorities in the main seem to agree. Dr. Barnett (9) says albumin is rarely found in insanity. Dr. Raban (10) agrees with Dr. Richter that albumin is not frequently present, and if it is present, is not connected with the cerebral disease.

Dr. Savage (11), after examining several hundred specimens, says that albumin is not common in acute cases of insanity. Kippel states that small quantities of albumin are often present in the second stage of general paralysis. And Kappan (12) says albuminuria is

especially frequent in insanity where there is chronic Bright's disease, or arteriosclerosis, in acute delirium, epilepsy, and general paralysis. In the two hundred and two specimens examined I found albumin four times, or in about two per cent. of the cases. In one of these it was transient, while in the remaining three it was more or less permanent. None of these patients were general paralytics. In all these cases, however, albumin *per se* was tested for, though it may have been present as globulin, propeptone, etc.

No doubt the previously mentioned writers are correct in saying that albumin is rarely found in insanity, yet in the majority of cases coming to autopsy chronic kidney disease is shown to have existed. But why such a great disproportion should exist between the urinary and autopsy findings does not seem altogether clear. The writer would venture that in most cases albumin in one form or another would eventually be found if sought for often enough.

The question of glucose in the urine of the insane is one in which there seems to be a good deal of confusion. Thus Laillia, who has especially examined the urine of the insane for sugar, arrived at the conclusion that diabetes mellitus occurs more frequently in the insane than in the sane. "An assertion," Dr. McDowall says, "which has not hitherto received any support, and very probably never will, for it is certain that diabetics are very seldom found in asylums."

Dr. Dickinson, of Bethlem Hospital, a few years ago made a large number of observations, and in which he found traces of sugar in a considerable number of the cases. It may have been, as Dr. Savage points out in referring to Dr. Dickinson's report, that the reduction of copper was due to the presence of uric acid rather than to that of sugar. In the present cases there was often a reduction of copper due to the presence of uric acid. It need hardly be mentioned that the presence of albumin, earthy phosphates, etc., frequently leads to confusion in the copper tests. Arrayed against these two worthy observers we find an equal number of careful men who conclude that, broadly speaking, diabetes mellitus is not any more common in the insane than in the sane. In fact, Dr. Savage says, "I know of no direct relationship between diabetes and insanity." Confining ourselves more closely and taking up general paralysis, for instance, we find such remarkable results that it would and, perhaps, does offset the last-quoted opinion. Thus Laillia (12a), Modigan (13), De Wolf (14), and Kiernan (15) have shown and called attention to the relationship of general paralysis and glycosuria. Dr. Allan McLane Hamilton (16) examined the urine of twelve general paralytics at the Poughkeepsie State Hospital and found a varying quantity of sugar in all of them.

Referring to the cases included in this report, it might be stated that, generally speaking, glucose is not very much more frequent in the insane than in the sane. In these cases glucose was present six times, or a little

less than three per cent. Fourteen of the whole number were general paralytics in whom glucose was found twice, or in about fourteen per cent. of the cases.

In all the cases examined three tests for glucose were applied, and in the doubtful ones several in addition. It is not asserted that the tests and methods adopted were infallible, and that glucose never escaped detection, if present, especially in general paralysis, in which it may have existed as shown by the remarkable results obtained by that eminent observer, Dr. Hamilton. Yet, from a clinical standpoint, it seems safe to assert that glucose was not present oftener than has been stated. It was desired to show the curious relation that in true diabetes mellitus the amount of phosphates rises and falls in an inverse ratio to the amount of sugar, but, unfortunately for the object in view, no true case of diabetes mellitus presented itself. But in two cases of diabetes mellitus occurring in sane patients this relationship appeared to exist.

In the beginning it was stated that this report was but preliminary. It is intended to continue the investigations in a series of experiments in which I shall have the pleasure of assisting a member of this staff to determine the influence which certain classes of food have upon the urine and, incidentally, upon the mental as well as the general well-being of certain classes of patients here. We also hope to gather some information, if, as has been recently set forth by Strümpell and others, in those cases of temporary glycosuria in nervous diseases true diabetes is developed eventually, and if the glycosuria is due to nervous disease, or primarily and principally to digestive disorders which are so frequently associated.

Also the hint given by Haig, of St. Bartholomew's Hospital, and others, of the alliance of migraine and epilepsy due to excess of uric acid in the blood, and the errors of diet and digestion which bring about these excesses, as well as several other points already set forth, will be gone into so far as possible. In short, it may eventually be found in these experiments, as Hippocrates said in speaking of epilepsy—that this disease is formed from those things which enter into and go out of the body.

CHOLECYSTITIS.*

By JAMES E. MOORE, M.D.,

PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF MINNESOTA.

THE gall bladder is said to act as a reservoir for the bile, but inasmuch as its capacity is very small as compared with the whole amount of the bile secreted, it seems more rational to consider it a part of the excretory duct of the liver so situated that it acts as a safety valve during the active flow of bile into the duodenum. There is only one duct opening into it, so that the bile must come in and go out through the same opening. Physiologists teach us that the liver is constantly secreting bile, but every surgeon who has performed cholecystotomy knows that it is only at certain times after eating that the flow of bile from the fistula is profuse. It is evident, therefore, that the gall bladder does not act as a reservoir to accumulate the bile secreted between meals to be used later, but that it performs its function principally during the time of digestion. Patients with a biliary fistula learn from observation when to prepare for the flow. This all goes to prove that the gall bladder has no function to perform which differs materially from that of the gall ducts, and that it is only a diverticulum from the duct. Its mucous membrane is lined with the same variety of epithelium as the ducts, and it is composed of the same number of layers and tissues. The only difference between the bile in the gall bladder and that in the hepatic ducts is the presence of mucus and a larger percentage of cholesterol in the former. Physiologists are unable to account for the excess of cholesterol in the gall bladder because it contains only mucus-secreting glands. The horse, camel, and a number of other animals have no gall bladder. It has been removed from the human being many times without injury, and its only secretion is mucus; therefore, when it is inflamed, the danger is not from a retained excretion, but from the ravages of the inflammation.

We have another organ in one corner of the abdomen which has even less function than the gall bladder, but which, nevertheless, causes much suffering and many deaths.

While it is certain that the gall bladder is not so frequently the seat of inflammation as the vermiform appendix, I believe that it is more frequently affected than we are aware of. Richardson says that in his experience and that of the Massachusetts General Hospital cholecystitis is of more frequent occurrence than vulv-

lus, intussusception, or other forms of acute intestinal obstruction with which it is likely to be confounded. It is only a few years since we called appendicitis peritonitis, and extra-uterine pregnancy hamatocele. Is it not quite possible that we are calling cases of cholecystitis by some other name or names? The whole number of cases of inflammation in the right hypochondriac region is not so great as in the right inguinal region, but there are many cases of "cramps in the stomach," "colic," "liver complaint," "pleurisy," and "kidney complaint," accompanied by fever, that will be recognized in later years as inflammation of the gall bladder. Every physician and surgeon should become as familiar with Mayo Robson's point as he is with McBurney's point.

It is really remarkable how little literature there is upon cholecystitis. In most of our works on medicine and surgery the word is not found in the index, and in the vast majority of instances in which it is mentioned it is only an incident of cholelithiasis. I have gained the most information from an article in the June number, 1898, of the *American Journal of the Medical Sciences*, by M. H. Richardson, entitled *Acute Inflammation of the Gall Bladder*, and from an article in the July number of the same journal by J. M. Da Costa on *The Significance of Jaundice in Typhoid Fever*.

The cause of cholecystitis is infection, but the how and the why of the infection are not always easy to explain. The *Bacillus coli communis* is most common, but all of the pyogenic germs are found at times. It comes as a complication of typhoid, pneumonia, and all acute infectious diseases. Distention is a very frequent cause of cholecystitis. The gall bladder is then, like the distended urinary bladder, very prone to infection. The distention causes abrasions and circulatory disturbances, which offer a *locus minoris resistentiæ* for the ubiquitous germ.

Gallstones, as compared with their frequency, rarely cause an inflammation, because they are so light and smooth that they rarely cause an abrasion; but when they become impacted, causing distention, they are a frequent cause. It is when impacted in the common duct that they are most likely to cause cholecystitis, because when in the cystic duct they interfere with the entrance of the bile into the gall bladder and can not cause distention from bile. Malignant and other growths may cause cholecystitis by pressure upon the ducts and a distention. This fact will account for many of our excruciations in malignant disease of the upper abdomen, as in Case IV in this paper. The amount of distention surprising in some of these cases. In the case reported the gall bladder was fully enlarged to the size of a grape. It is reasonable to believe that distention is frequently caused by a closure of the ducts from inflammation or swelling of their own walls, but Richardson says that in practically all of his cases there was no inflammation of the ducts, no catarrh, no plugging of the common duct, and no general liver infection. Nature has so well guarded

* Read before the Minnesota Academy of Medicine, Minneapolis, January 4, 1899.

the opening between the bowel and the common duct that infection seems rarely to come that way. One of the recognized dangers of cholecystenterostomy, however, is from infection of the gall bladder through the opening, which in this case has no protection. Experiments on animals have demonstrated that ligation of the common duct is more apt to cause than to prevent infection.

It is probable that the most common channel of infection is through the blood. It is natural to expect that the blood in the portal vein, coming as it does from the intestines, would be full of bacteria, and Fütterer's experiments demonstrate that one of the functions of the liver is to excrete those bacteria. He demonstrated that germs introduced into the general or portal circulation are eliminated largely through the liver by way of the bile. Fütterer did not use the colon bacillus in his experiments, but Adami * did, and demonstrated to his satisfaction that the liver cells had a bactericidal action upon the bacillus. Adhesions between the bowels and gall bladder would offer a good channel of infection, but the adhesions found in operations in cholecystitis are usually recent and evidently secondary to the infection of the gall bladder.

The pathology does not differ from that of inflammation of any other organ of like structure. When the bladder is not greatly distended its walls will be somewhat thickened and the mucous membrane congested. The color will vary from a yellowish red to dark green. The serous surface will be congested and roughened, and recent adhesions to the bowels are often found. The contents are usually dark green in color and are composed of mucus, bile, and sometimes pus. When the contents are clear no inflammation is present.

The symptoms, when clearly defined, are those of an acute inflammation situated in the right hypochondriac region. Unfortunately, they are frequently obscure and misleading. When cholecystitis follows the passage of gallstones, or is due to the impaction of a gallstone in the common duct, the symptoms are those of biliary colic, together with those of an acute inflammation. A temperature of 102° or 103° F. is of not infrequent occurrence in an attack of bilious colic, but it is of comparatively short duration, and disappears promptly after the stone is passed. A chill, followed by a rise of temperature, pain, tenderness, and a tumor in the right hypochondriac region, will point to a cholecystitis. Vomiting is a very common symptom. Jaundice sometimes occurs.

The diagnosis in a typical case is comparatively easy, but many cases are atypical, and the diagnosis may be difficult or impossible. Every practitioner should remember that an acute inflammation of the gall bladder is one of the possibilities as a complication of typhoid, pneumonia and all acute infectious diseases. Since physicians and surgeons now realize that this disease

is not of infrequent occurrence, it is evident that we have often overlooked it in the past, for reported cases are comparatively few. Of the six patients whose cases are reported in this paper, one was called peritonitis, one was operated on for appendicitis, and one was treated for some time as typhoid. Three of Richardson's patients were operated on for appendicitis. It is most likely to be mistaken for appendicitis, because it resembles this disease very closely, and because at the present time we are inclined to call every inflammation in the abdomen appendicitis. It may be mistaken for acute obstruction of the bowels, and has, doubtless, many, many times been pronounced peritonitis.

In no case of acute inflammation in the abdominal cavity should we be satisfied with a diagnosis of peritonitis. The causes of inflammation formerly diagnosed as peritonitis are probably, in their order of frequency, appendicitis, salpingitis, cholecystitis, and acute obstruction of the bowels from various causes.

In doubtful cases of abdominal trouble in which it is a question between an obstruction, a tumor, or an inflammation, a blood count may show a leucocytosis, which is quite conclusive evidence of the presence of pus. This holds true in typhoid complications as well, because leucocytosis does not occur in an uncomplicated typhoid.

The diagnosis between this affection and appendicitis is often difficult and sometimes impossible. The gastric disturbance, pulse, and temperature are alike in the two affections. The diagnosis can be made only by distinct localization, but even this may fail, because each of these affections may extend into the territory of the other. When in doubt concerning these two affections, I would advise an exploratory incision in the appendical region, because appendicitis is of more frequent occurrence. Failing to find in the appendix a sufficient cause for the trouble, exploration should be made as far as possible with one or two fingers. Should it then be found necessary to explore the gall-bladder region, I believe that it is better surgery to make a second opening in that region than to extend the original opening, on account of the great danger of a subsequent hernia.

Cholecystitis has frequently been mistaken for obstruction of the bowels. The pulse is of no assistance in this diagnosis. When a decided temperature is present, it points toward cholecystitis, but cholecystitis can not be excluded by the absence of a high temperature, because the temperature in this disease is as unreliable as it is in appendicitis. Ordinarily this diagnosis can be made by careful palpation of the gall-bladder region, but when extreme distention of the bowels with diffuse tenderness is present, it may be impossible to detect a tumor, even when it is of considerable size. Distention of the abdomen points toward obstruction, but may be present with a cholecystitis when complicated by peritonitis. Leucocytosis would indicate suppurative cholecystitis.

When abdominal symptoms arise in typhoid or any infectious disease, the gall-bladder region should be care-

* *British Medical Journal*, October 22, 1898.

fully examined. This examination is especially indicated in typhoid, because a complicating cholecystitis is of not infrequent occurrence, and because the patient's mental condition may be such that he will fail to call attention to this particular locality.

It is at times difficult to distinguish between a cholecystitis and a pyelitis from the local and general symptoms, because they may be practically the same in both diseases. A careful examination of the urine will usually enable us to make the diagnosis. In one instance in my own experience, however, with pus and every other symptom of pyelitis, I found at the operation that the most serious trouble was an inflamed gall bladder full of gallstones, and after the stones were removed and the gall bladder drained the patient made a good recovery.

There are doubtless many mild cases of cholecystitis ending in resolution, as in Case VI in this paper, but they are quite uniformly mistaken for something else. The disease as we understand it now is certainly a grave one. Of fifty-eight cases of cholecystitis complicating typhoid, reported by Da Costa, thirty-nine were fatal. Of these thirty-nine deaths, twenty-two were due to perforation.

The principal dangers are rupture, sepsis, and gangrene. In some very acute cases in which an operation was performed at an early date the gall bladder has been found in a gangrenous condition. Through early diagnosis and prompt treatment a very large percentage of the patients suffering from the graver forms of this disease can be saved.

This is a surgical disease and should always be so considered, but in cases of mild inflammation, with little or no distention, the case should be watched and treated expectantly. I question the wisdom of the popular dose of calomel in these cases, because the ducts and gall bladder are having trouble enough to do the usual amount of work without asking them to do extra work. A mild laxative like castor oil, with rest in bed, is the best treatment, and is all the treatment needed in mild cases. Opiates should be avoided in this disease, as in appendicitis, lest they mask the symptoms.

It is no more necessary to operate in every case of cholecystitis than it is to operate in every case of appendicitis, but when a severe inflammation of the gall bladder exists, or when an inflammation not so severe is accompanied by great distention, an operation affords the only rational treatment. The gall bladder must be opened and drained. The operation is not dangerous *per se*, and when indicated is very much less dangerous than waiting. It is indicated in cases complicating typhoid and other diseases, just the same as in idiopathic cases.

When the gall bladder is found in a gangrenous condition, as sometimes happens, the surgeon's only recourse is to perform a cholecystectomy, and drain.

I have always made my incision along the outer margin of the right rectus muscle, beginning at the tenth rib and extending downward from an inch and a half to

two inches and a half, and have been perfectly satisfied with it. When the disease is complicated with an impacted stone, it will be necessary to extend the opening downward, and if necessary the rectus may be cut across. The distended gall bladder will often appear in the opening as soon as it is made. The contents should be drained off with a trocar, so as to avoid soiling the peritonæum. The bladder should then be drawn into the wound, and after surrounding it with gauze it should be opened. The opening should be large enough to admit an exploring finger. Stones should be removed when present, and the edges of the wound in the bladder fastened to the fasciæ in the upper end of the abdominal wound with numerous stitches of fine black silk. A medium-sized rubber tube should be introduced far enough to reach well down into the bladder, but not infringe upon the bladder walls. A strip of gauze should be wound around the outer end of the tube and a safety pin passed through it to prevent it from slipping into the bladder.

When the peritonæum has not been soiled the wound should be closed. When it has been soiled a gauze drain should be introduced for forty-eight hours. I apply a light gauze dressing, allowing the drainage tube to protrude through it. I then take a piece of rubber dam about a foot square and draw the end of the drainage tube through a small hole in the centre of it and fasten it with a safety pin. An outer dressing can then be applied, which can be changed as often as necessary without disturbing the dressings next to the wound.

In the majority of cases the bile will begin to flow in two or three days. This is usually true when the duct seems to have been obstructed at the time of the operation. At the end of a week the tube and stitches should be removed. The sinus will usually heal in from three to six weeks, but remains open much longer in some cases. The patient is confined to bed from two to six weeks, according to the nature of the case.

I have selected six cases from those coming within my experience to illustrate the subject in a practical way rather than to reflect great credit upon the operator.

CASE I.—In 1880 I was treating a nine-year-old girl for an attack of pneumonia. She seemed to be doing well until about the middle of the second week, when she had a chill followed by a very high fever and very severe pain in the right hypochondriac region. Her suffering was intense, and she rapidly developed a peritonitis, from which she died. At the post-mortem we found a typical pneumonia of the right side, and a large abscess between the liver and the transverse colon, which was due to a ruptured suppurating gall bladder.

In those days we knew nothing of the pneumococcus, but this abscess was doubtless due to invasion of the gall bladder by this germ. At the present day a diagnosis should be made in a case of this kind and an operation performed which would probably save the patient; but in 1880 very little was known of the disease, and I, at that time a young country practitioner, was surely excusable for making my diagnosis at a post-mortem. One of the

most remarkable facts in the history of medicine is that practitioners of high and low degree had been making post-mortems in cases of peritonitis with local findings, such as I describe, for ages before we realized that peritonitis is a secondary lesion.

CASE II.—In the winter of 1893 I was called to see a man twenty-six years old, who four days previously had been suddenly attacked with severe pain in the abdomen, accompanied by vomiting and gradually rising temperature. When I first saw him his abdomen was slightly distended, his temperature was 102° F., and his pulse 100. There was marked tenderness and resistance over the right side of the abdomen. My diagnosis was appendicitis, and I advised that he be taken to St. Barnabas Hospital for an operation. Some time was lost in gaining the consent of the friends to an operation, so that when he arrived at the hospital his pulse was 110 and his general condition bad. I made the usual incision for an appendectomy and found a large abscess and a healthy appendix. The abscess extended up along the outside of the ascending colon. In those days we knew less about appendicitis than we do now, and we still were inclined to adhere to the idea that some of these cases of abscess in the right inguinal region were due to a perityphlitis. I remarked at that time that this was clearly not a case of appendicitis and that it must be a case of perityphlitis, and two days later I made a post-mortem to demonstrate the correctness of my diagnosis, only to find that the abscess was due to a ruptured suppurating gall bladder.

At the present time, owing to better education of the laity as well as of physicians, such a case would be turned over to the surgeon earlier, and the surgeon, finding an abscess located as this one was, and a healthy appendix, would at once think of the gall bladder as a possible origin, and would immediately explore that region and possibly save his patient. He certainly would not have his brain befogged with visions of perityphlitis. These two cases demonstrate Nature's method of confining an abscess to one part of the abdomen. In Case I a pouch was formed under the liver by adhesions between the transverse colon and the abdominal wall. In Case II the ascending colon was adherent to the abdominal wall, confining the pus to its outer side.

CASE III.—July 31, 1898, I was called to see E. L. W., a mail carrier, aged forty-five years, who had been attacked three weeks before with severe pain in the right side just under the liver. Dr. Bernard was called and diagnosed a gall-stone. The patient went to work in three days, but was not well enough to cover his route. On July 29th he had a second attack of pain in the right hypochondriac region which extended up to the shoulder.

He vomited frequently and had chilly sensations. On the 30th his pain was less severe, but he had a temperature of 102° F. On the evening of that day he had a severe chill followed by a temperature of 103° F. There were tenderness and resistance to pressure under the liver. Dr. Bernard made a diagnosis of cholecystitis. On the morning of the 31st I confirmed the doctor's diagnosis and had the patient removed to St. Barnabas Hospital for operation. At this time his pain was in-

tense, and a mass could be felt in the gall-bladder region. I made an incision along the outer side of the right rectus, and as soon as the opening was made in the peritoneum the gall bladder came up through the wound. It was greatly distended and was adherent to the under surface of the liver over quite an extensive area. There were no intestinal adhesions. I passed a finger through the foramen of Winslow and examined the common duct, but could find no stone. An opening was made in the gall bladder allowing about a pint of thick, dark, viscid liquid to escape. The mucous membrane was thickened and looked as if it was covered with granulations. The edges of the opening were stitched to the fascia in the upper end of the abdominal wound, and a rubber drainage tube introduced. No stone was found and none ever came from the wound. It is quite possible that a stone passed at the first attack, which caused abrasions resulting in the inflammation, but it is also possible that all of the symptoms were due to the inflammation.

On August 1st his pulse was normal, temperature 100°, and he was free from pain. After the second day the patient's temperature ran up to 102° F. every afternoon and down to 100° F. in the morning. After the third day there was a free discharge of seemingly healthy bile through the tube, and the patient became quite jaundiced.

August 8th.—Removed the tube and found the wound healthy. Found dullness over a large area of the right side due to pleuritic effusion.

9th.—Removed two quarts of bile-stained fluid from the pleural cavity. No enlargement of the liver; temperature, 102° F.; patient feels well, eats well, sleeps well, and looks well, except for a slight jaundice.

12th.—Temperature normal for the first time. In three weeks from the date of operation the patient went home, feeling well, but with the sinus open.

The pleuritic effusion coming on a few days after the operation was an interesting feature of this case, and I might think that it had come on coincident with the inflammation of the gall bladder, and had been overlooked, were it not that I, Dr. Bernard, and my internes had gone over the whole chest repeatedly. Cultures were being made from the contents of the gall bladder on the day of the operation, but an accident befell them so that I received no report. This patient was unable to begin work as a mail carrier until October, and in November reports that he is making full time, and never felt better in his life. The sinus still discharges some, particularly in the morning when he first gets up.

CASE IV.—In August, 1898, I was called by Dr. J. T. Moore to see H. L., a large, fleshy German, sixty-one years of age, who was suffering from severe jaundice, and who had been in failing health for some time. Our diagnosis was a malignant growth involving or pressing upon gall ducts, causing jaundice. I advised against even an exploratory operation on account of the size and condition of the patient.

About two weeks later I was called again, because the patient had developed some temperature and was suffering intensely. I then suggested that the pain might be due to distention and inflammation of the gall bladder and that an operation might relieve the suffering. The patient expressed himself as being anxious to undertake

anything that would afford him relief from his extreme suffering.

On August 24, 1898, at St. Barnabas Hospital, I made an opening at the usual location and found a greatly distended gall bladder, which I fastened into the abdominal opening and drained. The distention was so great that a uterine sound was not long enough to explore with. We found a carcinoma of the pancreas, to which the patient succumbed in a very few days, but the relief from suffering after the operation was almost complete, and we all felt that our effort on his behalf had not been in vain.

Is it not quite probable that in many cases of malignant growths, so located as to cause obstruction of the common duct, much of the pain is due to the distention and consequent inflammation of the gall bladder, and, if so, is it not good surgery to establish a biliary fistula solely for the relief of pain?

CASE V.—S. O. W., aged thirty-one years, carpenter. On the afternoon of April 10, 1898, while at work he began to feel a dull, aching pain, which would come and go. Had not slept all that night. On April 11th he called a doctor and was given medicine to relieve pain. He had had a similar attack four or five years before, and was told that his present attack was probably appendicitis. On April 12th he suffered pain when he moved, but was comparatively comfortable when quiet. On that day he came from his country home to St. Barnabas Hospital. He then had a pulse of 104 and temperature of 100° F. His abdomen was distended and rigid, and he had pain and tenderness from the liver to the ilium on the right side. He was suffering from a gonorrhea recently contracted. The urine was normal, except for evidences of gonorrhea. He was examined by Dr. Stewart, who did not confirm the diagnosis of appendicitis, and referred him to the medical side. He was given a mild laxative, rest in bed, and an ice-bag over the right side. He remained in about the same condition with a slightly rising temperature until April 16th, when it reached 102.4°. He complained of pain and was constipated. He was given codeine in half-grain doses.

On April 20th, one week after arriving at the hospital, his pulse was 94, temperature 101.8° F. He was suffering some pain and was very restless; his urine was normal in weight and reaction, but contained some sediment in which pus cells were found in large numbers. A blood count showed leucocytosis, about thirty thousand to one cubic millimetre. He was put on a milk diet and one-sixtieth-of-a-grain doses of strychnine. At this time he was comparatively comfortable, but "looked septic."

On April 27th, just seventeen days after the beginning of his attack, he was turned over to the surgical side with a diagnosis of pus in the abdomen, location undetermined, but probably in the liver.

Dr. Stewart, who was on duty at that time, called me in consultation, when I saw him for the first time.

He had a pulse of 88 and a temperature of 100° F., coated tongue, constipated bowels, and had a bad look. His abdomen was slightly distended, and there was an increased area of dullness and tenderness in the liver region; the blood count was twelve thousand leucocytes to one cubic millimetre. A mass could be felt in the right hypochondriac region. Our diagnosis was a probable suppurative cholecystitis with the possibility of an abscess of the liver. We advised immediate operation.

On April 29th I was present when Dr. Stewart operated and found a greatly distended gall bladder full of pus. There were very extensive adhesions in every direction. Drainage was established, and the patient's temperature became normal the next day. He gradually improved, and was discharged on June 2d with an open sinus. No bile ever escaped from the wound and there was no jaundice.

I have reported this case because, while I was only consultant, I found it of much greater interest than a number in which I have operated. The pus was sterile at the time of the operation, but it would be very interesting to know whether or not the infection was from the gonococcus.

The gonorrhœal complication interfered very materially with a correct diagnosis, because it was very difficult to decide that the pus did not come from the right kidney. The diagnosis was so very easy after the abdomen was opened that we were forcibly reminded that an exploratory operation made many days before would have saved the patient much suffering and all the dangers of a perforation.

Some time after leaving the hospital the patient reported that he was in excellent health, but that the sinus was still open. He evidently has an obstruction of the cystic duct, but whether from an impacted stone or from inflammatory deposit, it is impossible to say.

CASE VI.—On November 5, 1898, I was called by Dr. Strout to see Mr. J. B., a man, aged thirty-five years, a carriage-maker, who had been attacked one week previously with severe pain in the gall-bladder region. A diagnosis of bilious colic was made and a hypodermic of morphine was given, which relieved him of most of his pain. He vomited considerably and had some fever from the first.

When I saw him he was comparatively comfortable when quiet, and had a temperature of 101° F. He was slightly jaundiced, just noticeable in the conjunctiva. He had marked tenderness in the gall-bladder region, and while a distinct tumor could not be made out there was decided resistance upon pressure. His urine was quite dark-colored, but otherwise normal. Our diagnosis was cholecystitis, and I advised a dose of sweet oil and rest in bed. His fever and soreness gradually disappeared, so that in ten days from the beginning of his pain he was able to get out of bed. I believe that this was a typical case of mild cholecystitis, a class of cases very commonly overlooked. Whether or not the original pain was due to the passage of a stone I do not know, but owing to the fact that he gave no history of previous attacks, and that his acute pain was so quickly and permanently relieved by a hypodermic injection, I believe that it is quite rational to conclude that it was a mild inflammation due to causes other than gall-stones.

The Via Vitæ.—The *Medical Bull* for March cites the following:

"There are so many perils between the cradle and grave that it is a wonder that a man ever gets from one to the other," said an Irishman.

He wouldn't if it were not for woman.—*Ed. N. Y. M. J.*

THE UNITED STATES ARMY RATION, AND ITS ADAPTABILITY FOR USE IN TROPICAL CLIMATES.

By LOUIS L. SEAMAN, M. D.

HISTORY has shown us that the greatest single influence in the civilization of the world during the last half of the nineteenth century has been the liberal colonial policy of Great Britain. In lands of conflict and chaos she has established peace and prosperity and evidences of enlightenment, as witnessed in India, Burmah, East Africa, and Egypt.

Our own country has taken or is taking its initial step in this same great movement, and the development of the tropics, its peoples, and its soils, the richest and most productive of the globe, has become a subject of the greatest importance to us all.

It is not germane to this paper to discuss this subject save in one light. The initial instrument in establishing law and order in our new and misgoverned lands is the army. Adequate garrisons—in the opinion of those high in authority, fifty thousand men at least—will be required to maintain discipline in these new possessions. The first responsibility of the government should be the proper care of its guardians. Nothing is more costly than disease; nothing more economical than health.

In the Spanish-American war just concluded, the United States soldier who saw service in the Cuban and Porto Rican campaigns passed through several ordeals he should never be called upon to repeat. This paper relates only to one—namely, his experience with tropical diseases without a suitable dietary. The report of the adjutant general of the army, September 30, 1898, gives the number of those who died from wounds during the few brief weeks of actual hostilities as 345; but the hospital records show appalling lists of sickness and death, the mortality from disease alone reaching 2,485, or about eighty per cent. Had these proportions been reversed, the figures would have been nearer those to be expected in an age so advanced in sanitary science and dietetics. For the time from the landing of the army at Siboney and the fight at San Juan Hill to the signing of the protocols, a period of less than seven weeks, was an interval too short for disease other than that of an epidemic or preventable character to develop into serious proportions, especially when the class of men exposed were those selected for the special service. It is true the conditions encountered were somewhat formidable, the season of invasion being the worst that could have possibly been selected, the heat and moisture of the summer months combining to produce that extreme relaxation of the system which was a factor in the production of the many forms of tropical diarrhoea among the troops. But we must look beyond climate for the full responsibility.

From earliest times, history has shown that there has always been a greater mortality from disease among

armies during a war than from wounds, especially in tropical countries; and Spain, keen in her appreciation of this fact, and knowing also that she *had* to fight, courted a summer encounter, convinced that the enemy which would devastate our ranks was disease, rather than the guns of her Morros. In this she was right; but the aid received by the Spanish from the source mentioned was much greater than it would have been had our troops been appropriately fed. Duncan, the highest recognized authority in military hygiene, states in reference to campaigns in the tropics that, "although there is an undoubted distribution of disease, yet it is important to remember that so far from being unable to cope with it, we can act in antagonism to it. Take the class of bowel complaints: by insuring wholesome food, solid and liquid, we can remove all causes of irritation from within; by insuring a rational dress, we can remove all irritation from without. Again, in the matter of conservancy, by insuring the absence of putrefaction from the camp, and the burning or disinfection of the excreta, we cut the ground away from the feet of cholera, enteric fever, yellow fever, and bowel complaints. The army sanitary commission, relative to the rate of invaliding in Madras, distinctly states, in its memorandum of March, 1880, that much of the loss from invaliding from Indian climates is due to the continued action of eating, drinking, and clothing directly opposed to the requirements of the climate." After having considered the factors of temperature and moisture as applied to hot climates, he further says: "There are two remaining great elements—namely, fatigue and insufficient nourishment—to guard against. Indeed, it has been held that climate *per se* is secondary to these; doubtless, as regards temperature and moisture, this is the case, for if a man be properly fed and not overworked—that is, if his mechanical work be proportioned to his individual powers, and his food in accordance with his proportioned work—the factors of temperature and moisture will have but little power on him, except in extreme instances."

For a moment permit me to call your attention to the chart of temperatures as they existed in various parts of our country December, 1898, January and February, 1899.

Range of Temperature in United States Territory.

From published reports of the signal service bureau, the temperature was as follows:

<i>February, 1899.</i> —Alaska ranged as low as — 50°	
<i>January 31, 1899.</i> —White River, Canada,	
(near Fort Brady,	
United States)	— 40°
" " Green Bay	— 26°
" " Kansas City	— 4°
" " New York	+ 16°
" " Key West	+ 60°
<i>December 24, 1898.</i> —Santiago de Cuba . . .	+ 70°
" " Manila	+ 90°
" " Havana (in the sun) +	+ 104°

Extreme variation, 154° F.

Captain C. E. Woodruff, United States army, now stationed with the army in Manila, in an admirable article on Military Food, published in the *Journal of the American Medical Association* in 1892, uses the following simile: "If two ships were to start from New York, each to be absent several years, one in the arctic regions and the other in the tropics, no one would ever dream of provisioning them alike. Yet, if two armies were similarly to start from New York for long periods, one to the extreme North and the other to the hottest parts of the South, the law presumes that both shall carry essentially the same rations. We have not yet reached the point where it is decidedly recognized that the variety in the ration must be great enough to permit of sufficient flexibility to suit extremes of climate."

In a country of such wide ranges of temperatures as the chart indicates, the health of the soldier on active service or in garrison rests primarily upon his being provided with food and clothing suitable to his environment. The government, liberal in all things, freely issues these supplies; but, strange to say, while making certain distinctions in the uniform of the soldier who must endure the rigors of northern winters and the soldier on southern or tropical service, there has never, apparently, been any official consideration given to the diets which climates of such radical differences require. The same ration serves in all sections, and, while it is generous in quantity and usually excellent in quality, it is not such a one as can be universally used in hot and cold climates alike, if due regard is to be paid to the health of the soldier. Rich in nitrogenous, heat-producing elements, it is better adapted for the bodily needs of the soldier stationed in the North; but in extreme southern latitudes and in the tropics it proves an active agent of disease, overheating the system and producing those conditions predisposing to fevers and intestinal and rheumatic diseases, and rendering the labors of the surgeon unavailing. "The enormous number of cases of rheumatism," says Woodruff, "occurring during the Rebellion and since the Rebellion in veterans may not be entirely due to exposure, as popularly supposed. These men were hardened to exposure and should not have had more rheumatism than hunters or trappers or the aboriginal Indians. The limited, often insufficient ration and the absence of fresh articles of diet may have been one of the factors at work." The intimate relationship between diet and disease is a consideration demanding our closest study.

At the beginning of the century the ration of our army, established by an act of Congress, consisted of the following articles: Fresh beef, a pound and a quarter; or salt beef, one pound; or salt pork, three quarters of a pound; bread or flour, eighteen ounces; and for every hundred rations issued, a gallon of whisky, four quarts of vinegar, and two quarts of salt.

In 1808, Dr. Edward Cutbush, of the United States navy, commenting upon it said: "With respect to the

component parts of the ration, I think it defective without an allowance of vegetables or pulse occasionally in garrisons." And again, "The ration of meat should be diminished, and plenty of vegetables issued in lieu thereof."

Whether Dr. Cutbush's article had anything to do with it or not (departmental movements are slow in the army), the ration in 1818 was vastly improved by the addition of dried vegetables. In 1861, at the outbreak of the civil war, it was still further expanded, but in 1864 it went back again to what it had been prior to 1861. In 1890 it experienced another change, fresh vegetables again being added. I am not aware of any great changes made in it during the past eight years. To-day it is composed as follows: Fresh beef or fresh mutton, when the cost does not exceed that of beef, twenty ounces; or pork or bacon, twelve ounces; or salt beef, twenty-two ounces; or, when meat can not be furnished, dried fish, fourteen ounces, or pickled fish or fresh fish, eighteen ounces. Flour or soft bread, eighteen ounces, or hard bread, sixteen ounces; or corn meal, twenty ounces. Baking powder for troops in the field, when necessary for them to bake their own bread, $\frac{1}{8}$ ounce. Beans or peas, 2.4 ounces; or rice or hominy, 1.6 ounce. Potatoes, sixteen ounces; or potatoes, 12.8 ounces, and onions, 3.2 ounces; or potatoes, 11.2 ounces, and canned tomatoes, 4.8 ounces, or 4.8 of other fresh vegetables. Coffee, green, 1.6 ounce, or roasted coffee, $1\frac{3}{8}$ ounce; or tea, $\frac{3}{8}$ ounce. Sugar, 2.4 ounces; or molasses or cane syrup, $\frac{1}{2}$ gill; vinegar, $\frac{3}{8}$ gill; salt, $\frac{1}{2}$ ounce; pepper, black, $\frac{3}{8}$ ounce; soap, $\frac{1}{2}$ ounce; candles, $\frac{5}{8}$ ounce.

This is the ration the soldiers in the Northern States and Alaska were drawing in the winter of 1897-'98, and, without any change in a single constituent, it was the food intended, but not provided, for the American troops in Cuba, Puerto Rico, and the Philippines, where the temperature ranged between 85° and 95° F., and frequently reached much higher figures.

The ingestion of food is to effect two results—the development of body heat and bodily motion or energy. As a general proposition I might state that the latter is stable, and that similar motions will produce similar amounts of heat, the quantity and quality of food necessary to respond to this demand being determined by occupation. On the other hand, the quantity and quality requisite to maintain body heat will vary with exposure and environment. The individual laboring in the open air will require foods of greater heat-producing power that he who is employed within doors; and he who lives in a cold climate must eat more of the starches and fats to produce the body heat necessary for existence than he who lives in the tropics. For with an increase of external temperatures less body heat is required, and the appetite for fat, which was strong in the cold climate, will diminish proportionately. To quote once again from Duncan: "The normal relation of income

and expenditure has been calculated to a certain degree of exactitude. Taking Ranke's well-known standard diet, it is found that it yields about a million units of force or metre kilogrammes. Now, a good day's work equals one hundred and fifty thousand metre kilogrammes. Subtracting this from the total would give 850,000 metre kilogrammes as expended in heat production; or, in other words, a sixth of the total income of food is expended as mechanical force and five sixths as heat."

Dr. Carpenter on this question (the lesser production of body heat where the external temperature is increased) puts it thus: "Every change in the organic components of the body in which their elements enter into new combinations with oxygen must be a source of development of heat; and as a considerable portion of the carbon dioxide and water exhaled in respiration is formed within the body by the metamorphosis of its own tissues, and since the metamorphosis is promoted by the active exercise of the nervo-muscular apparatus, it follows that in animals whose habits are peculiarly active, living in climates in which the surrounding temperature is high enough to prevent any cooling influence, the combusive process thus maintained may be adequate for the maintenance of the temperature of the body at its own normal standard. Hence, here it would appear that we do not want to provide for the heat of the body in the tropics, but only for the work done *where there is a peculiarly active life.*"

Carpenter next says that the general experience of inhabitants of warm climates is in favor of a diet chiefly or entirely vegetable, inasmuch as such a diet affords an adequate supply of the albuminates in combination with the other classes of food, without affording more fuel than the system requires.

These statements have an especial interest when considered in conjunction with the *adaptability* to the tropics of our own army ration. The life of the soldier was sufficiently active to "maintain the temperature of the body at its own normal standard," the surrounding temperature in the West Indies having been "high enough to prevent any cooling influence"; and without the assistance of a "highly animalized diet," such as our ration was and is to-day. My own experience, and that of others, agreed with the "general experience of inhabitants of warm climates." We had little craving for meat, our appetites, on the contrary, inclining us toward vegetables and fruits. Left to natural selection, the appetite will always incline to the food supplied by Nature in the particular climate of the individual's environment; and any unusual craving for food primarily belonging to another zone is unnatural and due to an artificial appetite.

The food products of each zone will be found in every case to be those that are peculiarly adapted to the particular needs and requirements of the zone's inhabitants, and where the climate creates a demand for an

excessive animal diet, Nature furnishes it, or *vice versa*. A glance over the earth's surface will show this. In the arctic regions there is a great dearth of edible vegetation, but animals and fish abound, whose flesh, fats, and oils furnish the rich heat-producing foods required by the people who live in those lands of almost perpetual snow and ice. In the tropics these conditions are reversed. There is a scarcity of animal food, but an abundance of vegetation that yields nourishment with low heat-producing qualities. Between these extremes, in the temperate zone, we find a mixture of both and each in plenty. And here it might be well to pause and review the procession of the seasons of the temperate zone, observing the effect each has upon the food desire, and the means Nature has taken to meet it. As the spring days lengthen and become warmer, the early garden vegetables make their appearance; summer with its increased heat brings a profusion of vegetables and fruit, the supply of which gradually decreases as autumn approaches; and winter finds us with few fruits and vegetables that can be kept through its icy months, but with butcher shops well stocked with savory meats. With these changes our appetites are in perfect sympathy. The early spring vegetables are eaten with a keen relish, our tables in the summer months bear more vegetables and fruits, and in the winter the large roasts and steaks again have the place of honor, and small side dishes are sufficient for all the vegetables our appetites crave. Dr. Koerfer proclaims in the *Deutsche medizinische Wochenschrift* of last July that if Europeans would leave their pork fat, their meats, and their alcohol at home with their furs and heating stoves when they go to reside in the tropics, they would avoid all disturbances that are erroneously ascribed to the climate, but which are, in fact, only due to the failure to conform to Nature's laws. He considers that Nature makes the food conform to the climatic conditions—from the fish-oil polar zone through to the pork-fat temperate zone to the olive-oil and vegetable tropic zone. He writes from an experience of several years in the tropics, and adds that he felt better subjectively when actively employed than when lounging, no matter how high the temperature.

I am aware that many of the inhabitants of the temperate zone make but little change in their dietary as the seasons vary; but how many cases of dyspepsia, indigestion, and other ills do we not treat yearly, and how many more ailments and diseases, particularly in middle age or advanced life, could be traced to this very cause if we but carried our investigations back to the root of the disorder!

Let me invite your attention for the moment to the ration of the British soldier in India for the purpose of contrasting it with our own. It consists of the following articles: Meat, with bone, sixteen ounces; bread, sixteen ounces; potatoes, sixteen ounces; rice, four ounces; sugar, 2.5 ounces; tea, 0.71 ounce; salt, 0.66 ounce.

You will observe that the meat component is less by from four to six ounces than that of the United States ration, although Tommy Atkins is one of the meat eaters of the world. The bread allowance is less by two ounces, but the rice is greater by 2.4 ounces.

The potential energy of the American ration as compared with the ration of the British soldier is more than a fourth greater, when expressed in caloric units—the American being 3,800, the British 2,800; while the caloric units in the ration of an English prize fighter, as given by Gillespie, of Edinburgh, is but 2,200. In both the English and American army ration the proportions of proteids and carbohydrates are equal, the excess in heat equivalent in the United States ration being in its larger proportion of fats.

Stewart Clark, inspector-general of prisons, N. W. Provinces, India, in his *Practical Observations on the Hygiene of the Army in India*, says that "even this ration of the British army is, perhaps, more faulty in being too liberal than in any other respect; for it is now well known that the quantity of food in a tropical climate is much more frequently to blame than the quality in causing impaired health, such as disorders of the liver, dysentery, diarrhoea, and other complaints attributed to the climate." After stating that the most abstemious are the healthiest men in India, he further says that no change contributed more to the health of the European resident than the discontinuance of heavy midday luncheons, and the reduction of meat in the bill of fare of the better classes to one meal a day. He adds that "the greatest defect in the diet of the European soldier is the want of a due amount of vegetables. If the want of a plentiful supply of this most essential article of diet is the cause of disease in other groups of individuals, why should it not be equally so among soldiers? In fact, they are often so badly supplied with vegetables that there can be no doubt that dysentery, diarrhoea, and other complaints, which often assume a scorbutic character, may in a great measure be attributed to this cause."

Even Dr. Benjamin Rush, physician-general to the Military Hospital of the United States, in his *Direction for Preserving the Health of Soldiers*, published in 1808, says: "The diet of soldiers should consist chiefly of vegetables. The nature of their duty as well as their former habits of life require it. If every tree on the continent of America produced Jesuit's bark, it would not be sufficient to preserve or to restore the health of soldiers who eat one or two pounds of flesh in a day."

These few citations which I have made, and I have made them because they especially bear out my own observations in the tropics, for no originality is claimed in this paper, will sufficiently indicate that the results of a too excessive meat diet in tropical climates furnish no new field for investigation. Why, among civilized people, meat should have continued to form a major part of the soldier's ration after its serious effects

have been pointed out by the best medical authorities for nearly a century is past comprehension.

(To be concluded.)

Therapeutical Notes.

For Nephritis.—The *Revue médicale* for December 14, 1898, quoting the *Journal de médecine de Paris*, attributes the following prescription to Neumann:

R Nitroglycerin 15 grains;
Rectified alcohol 150 "
Distilled water 600 "

M.

Eight drops to be taken in three divided doses in the day. If the medicament is well borne, the daily amount may be raised to twelve drops.

Benzoate of Mercury.—At a recent meeting of the French Therapeutical Society M. Desesquelle and M. Bretonneau (*Gazette hebdomadaire de médecine et de chirurgie*, February 16th) showed that, contrary to the received opinion, benzoate of mercury is not soluble in aqueous solutions of alkaline iodides and chlorides. Such so-called solutions of benzoate of mercury, they said, contained in reality benzoate of sodium and chloride or iodide of mercury. On the other hand, benzoate of mercury, they asserted, was readily soluble in an aqueous solution of neutral benzoate of ammonium, and, moreover, the benzoate of mercury in such a solution, thanks to the benzoate of ammonium, did not precipitate the albuminoids of the blood serum even after the addition of chloride of sodium to the solution of the mercurial salt. The authors found by experiments on rabbits that weight for weight of the combined mercury, benzoate of mercury was slightly less toxic than sublimate; but in any case the absence of albuminoid precipitation rendered it preferable for therapeutic use to the latter salt. For hypodermic injections they recommended the following formula:

R Benzoate of mercury 60 centigrammes;
Neutral benzoate of ammonium 8 grammes;
Distilled water, enough to make 60 cubic centimetres.

M.

In the following formula cocaine is associated with the benzoate.

R Benzoate of mercury .. 60 centigrammes;
Neutral benzoate of ammonium 3 grammes;
Cocaine 12 centigrammes;
Benzoic acid 60 "
Distilled water, enough to make 60 cubic centimetres.

M.

A Gargle for Lacunar Amygdalitis. The *Journal de médecine de Paris* for February 26th credits the following formula to Mouré:

R Borax, each, 5 parts;
Potassium bromide, 1 part;
Carbolic acid 50 parts;
Glycerin 150 "

THE
NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK F. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 18, 1899.

THE MEDICAL PROFESSION AND THE PRESIDENCY
OF THE NEW YORK BOARD OF HEALTH.

MANY of our readers are doubtless aware that, as at present constituted by law, the board of health of the city of New York consists of the president of the police board, the health officer of the port, and three health commissioners appointed by the mayor, two of whom must have been practising physicians for not less than ten years preceding their respective appointments. And there is this singular provision in the law: "The health commissioner who is not a physician shall be president of the board and shall be so designated in his appointment." For years the medical profession has been humiliated by this unjust and senseless discrimination. Now it is proposed, in assembly bill No. 1129, introduced by Mr. Bulkley, to so amend the statute, which is a part of the city charter, as to make the passage quoted read: "The health commissioner who shall be president of the board shall be so designated in his appointment," leaving the mayor free to appoint a physician president of the board if he deems it advisable to do so.

There was never any semblance of a good reason for hampering the mayor and stigmatizing medical men in the way the present law does those things. Nevertheless, although the anomaly has repeatedly been protested against, its correction has heretofore failed of accomplishment. There seems now, however, to be a good prospect of Mr. Bulkley's amendment being carried in the legislature. If it is carried, much credit will be due the committee on legislation of the Medical Society of the State of New York, and particularly its energetic chairman, Dr. Frank Van Fleet. Elsewhere in this issue we publish Dr. Van Fleet's letter calling upon physicians to press their demand for the abolition of the odious discrimination made against them in the present law. Every one of his arguments is sound, and we trust that those of our readers who live in the State of New York will urge the matter upon their senators and assemblymen. We can not afford to leave a stone unturned to deliver ourselves from our present disfranchisement.

THE DIAGNOSTIC SIGNIFICANCE OF THE
CANON-PFEIFFER BACILLUS.

If we admit that this organism is the cause of influenza, the practical value of its recognition in cases of disease seems likely to prove greatest in instances in which the influenza complicates other affections or is itself marked by unusual features. In a preliminary report by Dr. F. E. Wynekoop, first assistant bacteriologist of the Chicago department of health, recently issued by the department, we find it stated that in several instances the bacillus of diphtheria and that of influenza have been found at the same time in the throat, and the symptoms have usually accorded with this fact. The influenza bacillus, says Dr. Wynekoop, has been found present also in cases of scarlet fever, measles, and pneumonia, and in all these instances it has been noticed that there were clinical manifestations that were difficult to interpret until the microscopical examination was made.

Dr. Wynekoop goes on to say that in the diagnosis of cases suspected to be those of diphtheria some interesting observations have lately been made relative to obscure symptoms of that disease. In cases that appeared to be diphtheritic at the onset the presence of the Canon-Pfeiffer bacillus has been demonstrated, and the subsequent course of the disease has confirmed the microscopical diagnosis of influenza. In many of these cases, says Dr. Wynekoop, the throat symptoms were so marked—redness and swelling of the tonsils and a well-developed membrane—that a physician would not hesitate to pronounce the case one of diphtheria, yet influenza bacilli were found in a condition almost pure. Cases with little throat disturbance, but with a rise of temperature, bodily aching, and general depression, on the other hand, were found to be examples of mild diphtheria, in spite of the symptoms pointing to influenza. The influenza bacillus, too, was the sole micro-organism found in certain cases that appeared to be instances of amygdalitis or of severe laryngitis. Very few of the general symptoms of influenza were observed in these cases, and the diagnosis was made solely on the strength of the bacteriological examination, but was confirmed by the subsequent course of the disease.

Dr. Wynekoop remarks that it has occasionally been observed that when there is influenza in a household some member of the family is suddenly attacked with acute inflammation of the conjunctiva characterized by severe pain, swelling, redness, and a profuse discharge of pus of medium consistence and cheesy appearance. As the picture differs materially from that of ordinary acute inflammation of the conjunctiva, it has been sus-

pected that the bacillus of influenza might have something to do with the diseased condition, and that organism has been found in abundance in the discharge.

We are informed from the office of the Chicago department of health that since the January report was published the Canon-Pfeiffer bacillus has been found in the bronchial mucus of a number of patients presenting the characteristic symptoms of mumps. These symptoms, however, have not usually lasted more than three or four days, and then the swelling and soreness have subsided and the temperature has fallen to normal, but, coincidentally with the subsidence of the symptoms of mumps, there has occurred in some cases a sharp intestinal disturbance, with peritonitis and dysentery in two instances. All these cases have occurred in adults, and thus far none of them have proved fatal.

THE PRODUCTION OF SEX AT WILL.

FRIEDMANN (*Klinisch-therapeutische Wochenschrift*, 1898, No. 30, p. 1156; *Gazette hebdomadaire de médecine et de chirurgie*, January 8th), as a result of investigation into this problem, says that in order to resolve it these three questions must be answered: 1. Is it possible by artificially modifying the material exchanges to deflect from its primitive direction the normal course of the physiological functions of the organism? 2. Can any explanation be given of the fact that in certain families only boys, and in others only girls, are produced? 3. What are the most appropriate means to influence the material exchanges in the reproductive system of the animal organism so as to produce at will a given sex?

The first question has been amply answered in the affirmative by Darwinism. As to the second, he says that women with a tendency to the exclusive production of one or other sex present signs of a degeneration so marked as to constitute a pathological condition, a sort of androgenous or gynæcogenous cachexia.

Haeckel has shown that the phenomena of heredity must be attributed to physical and chemical causes, and that the sexual characters must preexist in the original germ before the definition of the genital apparatus. The androgenous and gynæcogenous cachexia must be meant to imply that the female element in the first, or the male element in the second, is destroyed by its opposite in some organic chemical process. Consequently, to answer the third question, it is necessary to seek for either the male or the female element deposited in the ovule a sort of toxalbumin, so that one of the two elements may predominate over the other. Empirically he finds in ovarine the substance to combat the female, and in spermine that to overcome the male element. By submitting a

female guinea-pig to the administration of tablets of ovarine from October 26, 1897, to February 15, 1898, he succeeded in obtaining the gestation of a single male normally developed. Another female similarly submitted to subcutaneous injections of spermine became pregnant with a single female. The uniparous pregnancy, he says, seems to indicate a lowered reproductive power.

There is a popular belief that excess of sexual ardor in the woman produces boys, while where the excess exists on the man's side, girls are commonly the offspring. The great preponderance of girls among first children and of boys among "love children" is regarded by some as partly confirmatory of this view. In the light of Friedmann's researches, it would seem possible that the relative degree of sexual ardor or vigor in the parents is at least a contributory factor in sex production.

MINOR PARAGRAPHS.

THE NEED OF LOGICAL DISCRIMINATION ON THE PART OF READERS.

JUDGING from correspondence which occasionally comes to hand, it seems desirable to remind readers at large that not everything which appears in the columns of a medical journal is necessarily indorsed by that journal. All editorial expressions, of course, represent the views of the journal; while original contributions are accepted mainly for one of two reasons—viz., either because they present something apparently new and worthy of consideration and investigation, or because, in the case of matters of opinion, the weight of the author's reputation justifies a respectful consideration of his views, whether upon examination the individual reader feels able to yield his assent thereto or not. These same reasons apply also in the selection of articles for reproduction from other journals. Science knows no such thing as "authority," as the expression is used by the schoolmen. Every member of the medical profession is supposed to be competent to form a judgment for himself on the reasonableness of matters set forth by others, though he may not himself have heretofore known of them. This is the object of his previous training, general and technical, and with him in the last resort must rest the responsibility of accepting unreservedly or reservedly, or of rejecting, the views or teachings which are merely brought by the editor as impartially as possible, and acting on the before-mentioned principles, to his notice.

ACIDITY OF THE MOUTH DURING SLEEP.

THE dentists tell us that an acid condition of the fluids of the mouth plays an important part in the etiology of dental caries, also that the causes of that affection are particularly active during the hours of sleep, when the saliva stagnates, so to speak, instead of being subjected to the agitation and renewal incident to the chewing and other movements that to some extent are almost continuous except during sleep. However carefully we may cleanse the teeth and rinse them with

antiseptic solutions on going to bed, therefore, we are guarding but temporarily against decay; it gains on us while we are asleep. Possibly those who suffer with insomnia may snatch a crumb of comfort from this reflection, but we fear there is in it no consolation for the mouth-breathers, for the desiccation of the mouth which takes place in them during sleep, while enough to give rise to considerable discomfort on their waking, is quite insufficient to hamper pathogenic bacteria in their work of destruction.

GRAVE SYPHILIS IN PHYSICIANS.

VON BRANDIS (*Deutsche medicinische Wochenschrift*, 1898, No. 21; *Monatshefte für praktische Dermatologie*, February 15, 1899) has met with a number of grave cases of syphilis among medical men. The initial lesion was on the finger, and the diagnosis was always a late one, and this fact probably serves to explain the gravity of the course pursued by the disease.

A USE FOR EXHAUSTED DRUGS.

In the March number of the *American Journal of Pharmacy* the editor of that journal, remarking upon the immunity of certain of the domestic animals against particular poisons, suggests that medicinal roots, rhizomes, fruits, and seeds, being rich in nutritive material, may economically be turned to account as food for animals, instead of being thrown away as of no value, after their medicinal constituents have been extracted.

GIGANTISM AND FEMININITY.

At a recent meeting of the Paris Society of Biology (*Gazette hebdomadaire de médecine et de chirurgie*, February 16th) M. Hallopeau showed a male giant who had no beard, whose mammary glands were considerably developed, and whose genitals were extremely small. On the lower part of the abdomen there were enormous varices, and M. Hallopeau suggested that these might have so pressed upon the vasa deferentia or the nerves of the testicles as to have caused their atrophy and consequently the femininity.

AMERICAN FLUID EXTRACTS.

In the *Province médicale* for February 25th Dr. F. Martz, of the medical clinic of the Lyons Faculty of Medicine, explains the processes by which the American fluid extracts are made, and recommends them for more extensive use in France as being quite as efficacious as the plants from which they are prepared.

RUPTURE OF THE VAGINA DURING LABOR.

In the *Journal* for November 5th we mentioned several instances of this accident. In the *Monatsschrift für Geburtshilfe und Gynäkologie*, viii, 3 (*Centralblatt für Gynäkologie*, March 4th), Dr. Van der Hoeven, of Amsterdam, relates another case in which the rupture was observed after version with difficulty in the extraction of the after-coming head. The whole circumference of the fornix was involved, except the anterior portion adjacent to the bladder. The edges of the laceration did not bleed, and a tampon was all that the author thought it necessary to employ. Recovery took place in eight weeks.

THE CITY BOARD OF HEALTH AND THE MEDICAL BOARD OF THE PRESBYTERIAN HOSPITAL.

In our present issue we publish some resolutions recently adopted by the medical board of the Presbyterian Hospital regarding the city board of health as it might be affected, in the hospital board's opinion, by the enactment of assembly bill No. 451. We should be sorry to see the board of health's usefulness crippled, but we do not believe in rewarding its achievements by giving it a virtual monopoly of any commercial product, be it antitoxine or anything else. Government, municipal, State, or national, must not enter upon the field of trade competition.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 11, 1899:

DISEASES.	Week ending Mar. 4.		Week ending Mar. 11.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	14	3	17	6
Scarlet fever.....	181	13	182	14
Cerebro-spinal meningitis.....	0	9	0	12
Measles.....	280	15
Diphtheria.....	167	27
Croup.....	9	5	11	5
Tuberculosis.....	244	172	178	202
Small-pox.....	7	1	0	0
Chicken-pox.....	49	0	37	0

Sulphur Fumes in Grippe.—Dr. J. Ashburton Cutter (*Georgia Journal of Medicine and Surgery*, February) says: An aged lady in England, when the epidemic was so severe some years ago, wrote to a medical gentleman in America, asking for relief from her grippe. She was advised to burn some sulphur, and a subsequent letter of gratitude testified to the first relief she had got. The author's mother, sick occasionally with grippe, would not take sulphur, as she asserted that it stung her nose. About fifteen months ago, while suffering from an attack, the diagnosis having been made with a microscope, it was decided that she should inhale burning sulphur, which she did, with a speedy cure of her "cold." Children sick with grippe will stand the strong fumes of burning sulphur, and laugh at their well elders, who have to go out of the room. Much more clinical evidence might be cited.

Tuberculous Perforation of the Velum Palati.—At the *Société médicale des hôpitaux*, M. Barbier (*Progrès médical*, January 28th) recently described a case of tuberculous perforation of the velum palati with tuberculosis of the tonsil and consequent glandular affections. Syphilis, it was asserted, had no part in the affection, and antisypilitic treatment only aggravated the malady, which was ameliorated by applications of ten-per-cent. lactic-acid solution and by overfeeding.

Rupture of the Diaphragm.—Dr. Mathew Porter, of Cincinnati (*Fort Wayne Medical Journal-Magazine*, February), reports a case of rupture of the diaphragm resulting from a fall down a flight of stairs. The patient was able to get to bed unaided, and considered herself not much hurt at the time, but she lived only two or three days. The earlier symptoms could not

be learned, owing to the fact that the patient was unable to give an account of herself when brought to the hospital, and had had no physician prior to that time. At the autopsy the diaphragm was found ruptured at the œsophageal opening to the extent of an inch and a half. All of the stomach, except the pyloric end, the transverse colon, and mesentery had escaped into the left side of the chest, pushing the heart to the right, and flattening the lung against the chest wall. The mesentery and colon were gangrenous. There were no symptoms of peritonitis. There was dullness on percussion from the sternum to the left axillary line from the third to the seventh rib, and over this area was to be heard on auscultation a sound resembling that which is made by shaking fluid in a partially filled cavity.

A Probable Result of Anticigarette Legislation.—The *British Medical Journal* for February 18th says:

"The supreme court of Tennessee has decided that the cigarette is not a legitimate article of commerce. This decision was given in an action brought to test the law passed some time ago by the State legislature prohibiting the sale of cigarettes. The supreme court has ruled that the law in question is constitutional, and must be enforced. The ingenious youth of Tennessee will now have a double pleasure when they snatch the fearful joy of a cigarette: they will be doing what is declared by their sanitary oracles to be hurtful to health, and what is declared by the highest legal authority to be unlawful."

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general of the United States Marine-Hospital Service for the week ending March 11, 1899:

Small-pox—United States.

Mobile, Ala.,	Feb. 25	1 case.
Los Angeles, Cal.,	Feb. 17-25	15 cases, 5 deaths.
Washington, D. C.,	Feb. 18-25	10 "
Washington, D. C.,	Mar. 1-4	5 "
Savannah, Ga.,	Mar. 2	1 new case.

Origin probably in North Carolina.

Jacksonville, Fla.,	Feb. 28-Mar. 4	3 cases.
Higgesville, Ill.,	Mar. 7	1 case.
Chiro, Ill.,	Mar. 7	26 cases.
Dana, Ill.,	Mar. 7	1 case.
Murphysboro, Ill.,	Mar. 7	2 cases.
Evansville, Ind.,	Mar. 3	1 case.
New Albany, Ind.,	Mar. 5	1 "

Indian Territory.—The secretary of the territorial board of health of Oklahoma states, March 1st, that nearly fifty deaths have been reported to him from Indian Territory.

Lewistown, Me.,	Feb. 25-Mar. 4	2 cases.
Watervliet Township, Mich.,	Mar. 2	1 case.
Onondah, N. Y.,	Feb. 18-25	3 cases.

The Boston Medical Society.—At the last regular meeting the following officers were elected for the ensuing year: President, Dr. Gustavus Liebman; vice-presidents, Dr. R. K. Noyes and Dr. J. S. Lockart; secretary, Dr. W. A. Butman; financial secretary, Dr. P. Sosnoski; and treasurer, Dr. I. Shapiro. Directors, Dr. L. Frumson, Dr. M. N. Goodman, Dr. V. Byehower, Dr. M. Gerstein, Dr. A. Rovinsky, Dr. C. Parker, and Dr. J. S. Lockart. The following resolution was unanimously adopted: *Resolved*, That the Boston Medical Society is opposed to and protests against the passage of the so-called Osteopathic Bill now before the Massachusetts Legislature.

The Medical and Surgical Society of the District of Columbia.—At the last meeting, on Friday evening, the 10th inst., the following papers were presented for discussion: Puerperal Sepsis; its Prophylaxis and Treatment, by Dr. Moran; and Antitoxine in the Treatment of Diphtheria, by Dr. Edwin L. Morgan.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Medicine, on Tuesday evening, the 11th inst., the following papers were presented for discussion: The Differentiation of Renal Discharges, by Dr. Thomas B. Carpenter; Acute Bright's Disease, by Dr. J. Henry Dowd; Chronic Bright's Disease, by Dr. Albert H. Wochner; and Primary Nephritis (Infantile), by Dr. George A. Hummelbach.

Resolutions on the Bill concerning the City Board of Health.—On March 13th the medical board of the Presbyterian Hospital passed the following resolutions: *Whereas*, The medical board of the Presbyterian Hospital believe that the health department of New York has, within the past few years, contributed most valuable services to the city in the prevention of the spread of infectious diseases, as well as by contributions to scientific medical research; and

Whereas, There is pending before the assembly a bill called assembly bill No. 454, which would embarrass and curtail this work of the health department, designed

to protect the health of the citizens of New York; therefore be it

Resolved, That this board do hereby earnestly protest against the passage of assembly bill No. 451, believing that such action would materially injure the interests of this community.

Resolved, That these resolutions be spread upon the minutes of this board and that copies be sent to the legislature, to the New York health department, and to the medical journals of this city.

[Signed.] W. P. NORTHRUP, M. D.,

Secretary of the Medical Board.

The Richmond Academy of Medicine and Surgery.—

At the last regular meeting, on Tuesday evening, the 14th inst., the subjects for discussion were Infantile Paralysis, by Dr. Charles A. Labenberg, and The Necessity of Medical Inspection in Schools, by Dr. Hodges.

The Medical Society of City Hospital Alumni, of St. Louis.—At the last meeting, on Thursday evening, the 16th inst., the decision of the committee on award in the prize competition for the two best essays on The Medical Inspection of School Children and the Hygiene of Schools was made known, and the names of the successful competitors announced.

The Late Dr. J. E. H. Nichols.—At the last regular meeting of the New York Otological Society, held January 24th, the following resolutions were adopted:

The New York Otological Society has learned with sorrow of the death of Dr. J. E. H. Nichols, which occurred in North Carolina on September 12, 1898. Dr. Nichols was a charter member, a constant attendant at the meetings of the society, and a most valued contributor to its scientific work.

Resolved, That in the death of Dr. Nichols the society has lost one of its most respected and valued members, and otology a faithful and scientific worker;

That the sympathy of the society be extended to his family in their sad loss; and, finally,

That these resolutions be spread on the minutes of the society and published in the *Medical Record* and in the *New York Medical Journal*.

Resolved, That a copy be sent to his family.

[Signed.]

J. B. EMERSON,

ALBERT H. BUCK,

GORHAM BACON.

} *Committee.*

Death of Professor Rutherford, M. D., F. R. S.—By the death of Dr. Rutherford, professor of physiology in the University of Edinburgh, which took place on February 21st from influenza, medical science loses a distinguished ornament and the University of Edinburgh a brilliant teacher and a man of light and leading. His name has been too long before the scientific world for his loss not to deeply affect university institutions of all countries. Professor Rutherford was sixty years of age.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 4 to March 11, 1899:*

BORTH, JOHN T., Acting Assistant Surgeon, is relieved from further duty at the General Hospital, Fort Myer, Virginia, and will proceed to Cincinnati.

DARNALL, CARL R., First Lieutenant and Assistant Surgeon, will proceed to Havana and report to the commanding general, Division of Cuba, for duty.

HARNETT, EUGENE H., First Lieutenant and Assistant Surgeon, is detailed as a member of the examining board at Fort Monroe, Virginia.

LAMB, D. H., Acting Assistant Surgeon, is relieved from further duty at the General Hospital, Fort Myer, Virginia, and will proceed to Owasso, Michigan.

LYNCH, CHARLES, Captain and Assistant Surgeon, is relieved from further duty at Fort Point, Galveston, and will report to the commanding officer, Sixth Infantry, for duty, to accompany that regiment to Manila.

MACLEAN, DONALD, Jr., Acting Assistant Surgeon, will proceed to Savannah and report to APPEL, DANIEL M., Major and Surgeon, for duty at that place.

MILLHOFF, CLARENCE B., First Lieutenant and Assistant Surgeon, is relieved from further duty at Washington Barracks, D. C., and will proceed to Savannah and report to the commanding officer, United States General Hospital, for duty.

ROBERTS, GEORGE W., Acting Assistant Surgeon, will proceed to Fort Porter, New York, and report to the commanding officer, Thirteenth Infantry, for duty, to accompany that regiment to Manila.

WAKEMAN, WILLIAM J., Major and Brigade Surgeon, will proceed to Philadelphia and assume the duties of attending surgeon and examiner of recruits in that city.

WHITTINGTON, WILLIAM L., Acting Assistant Surgeon, will report to the commanding officer, Sixth Infantry, for duty, to accompany that regiment to Manila.

The honorable discharges of the following medical officers for the volunteer army are revoked:

HARRIS, HENRY S. T., Major and Brigade Surgeon, who will proceed to Fort Crook, Nebraska, and report to the commanding officer, Sixteenth Infantry, for duty, to accompany that regiment to Manila.

KENDALL, WILLIAM P., Major and Brigade Surgeon, who will proceed to Plattsburgh Barracks, New York, and report to the commanding officer, Twenty-first Infantry, for duty, to accompany that regiment to Manila.

RAYMOND, HENRY I., Major and Brigade Surgeon, who will proceed to Fort Porter, New York, and report to the commanding officer, Thirteenth Infantry, for duty, to accompany that regiment to Manila.

Changes of Address.—Dr. Edward B. Coburn, to 313 West Fifty-seventh Street; Dr. F. T. Labadie, to No. 11 West Thirty-ninth Street; Dr. Thomas J. Leahy, from Cambridgeport, Massachusetts, to No. 303 Broadway, New York; Dr. James P. Tuttle, to No. 42 West Fiftieth Street.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending March 11, 1899:*

ANGENY, G. L., Assistant Surgeon. Detached from the Naval Hospital, Chelsea, Massachusetts, and ordered to the *Lancaster*.

ARNOLD, W. F., Passed Assistant Surgeon. When discharged from further treatment at the hospital, Norfolk, Virginia, he is ordered home and granted sick leave for three months.

GUTHRIE, J. A., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Virginia, and ordered to the *Franklin* immediately.

PAYNE, J. H., Jr., Assistant Surgeon. Detached from the *Franklin* and ordered to the Naval Hospital, Chelsea, Massachusetts.

ROSS, JOHN W., United States navy, retired, is assigned to Military Hospital No. 1, Havana, Cuba, and will report to the commanding officer of that hospital for duty.

Promotions.

CROWNSHIELD, A. S.; VAN REYPEN, W. K.; BRADFORD, R. B.; STEWART, E.; MELVILLE, G. W.; HICHBORN, P.; ENDICOTT, M. T.; O'NEIL, C., chiefs of bureau in the Navy Department to be rear admirals from March 3d.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending March 9, 1899:*

WHITE, J. H., Surgeon. To proceed to Elizabeth, N. J., for special temporary duty. February 24, 1899. To report at Washington, D. C., for special temporary duty. February 28, 1899.

CARRINGTON, P. M., Surgeon. To proceed to Baltimore, as inspector of unseviceable property. March 2, 1899.

PETTUS, W. J., Passed Assistant Surgeon. To proceed to Cape Charles City on special temporary duty. February 25, 1899. To proceed to Burlington, N. C., for special temporary duty. February 28, 1899.

COBB, J. O., Passed Assistant Surgeon. To report at Washington, D. C., for special temporary duty. February 25, 1899.

GUITÉRAS, G. M., Passed Assistant Surgeon. To proceed to Matanzas, Cuba, for duty as quarantine officer. February 25, 1899.

MCADAM, W. R., Assistant Surgeon. To proceed to Key West, Fla., and assume temporary charge of service. February 25, 1899.

BROWN, F. L., Hospital Steward. To proceed to Norfolk, Va., and report to commanding officer for duty. February 25, 1899.

HOLSENDOFF, B. E., Hospital Steward. Granted leave of absence for two days. February 24, 1899. Upon being relieved by Hospital Steward F. L. BROWN, to proceed to San Juan, Puerto Rico, and report to Surgeon A. H. GLENNAN for duty. February 25, 1899.

COBB, J. O., Passed Assistant Surgeon. To proceed to Savannah, Ga., for special temporary duty. March 2, 1899.

FICKES, L. D., Assistant Surgeon. To report at Washington, D. C., for special temporary duty. March 1, 1899. To proceed to the Reedy Island Quarantine Station and report to the medical officer in command for temporary duty. March 8, 1899.

RAMUS, CARL, Acting Assistant Surgeon. To proceed to the Cape Charles Quarantine Station and report to the medical officer in command for duty and assignment to quarters. March 6, 1899.

BROOK, C. H., Hospital Steward. To proceed to New Orleans, La., and report to the medical officer in command for duty and assignment to quarters. March 9, 1899.

BROWN, F. L., Hospital Steward. To proceed to the Cape Charles Quarantine Station and report to the medical officer in command for duty and assignment to quarters. March 6, 1899.

SLOUGH, CHARLES, Hospital Steward. To proceed to the San Francisco Quarantine Station and report to the medical officer in command for duty and assignment to quarters. March 9, 1899.

TROXLER, R. F., Hospital Steward. To proceed to San Francisco, Cal., and report to the medical officer in command for duty and assignment to quarters. March 9, 1899.

Board Convened.

Board convened to meet at the United States Marine Hospital, San Francisco, Cal., at 10 o'clock A. M., May 2, 1899, for the examination of candidates for appointment as assistant surgeon in the service. Detail for the board: GASSAWAY, J. M., Surgeon, chairman; BROOKS, S. D., Surgeon; GARDNER, C. H., Passed Assistant Surgeon, recorder.

Appointments.

T. FARRAR RICHARDSON, of Louisiana; W. W. KING, of Michigan; FRANK J. THORNBURY, of New York; and CARL RAMUS, of Illinois, commissioned as assistant surgeons. March 9, 1899.

WALLACE R. HUNTER, of Pennsylvania, to be acting assistant surgeon for duty at the port of Erie, Pa. March 9, 1899.

ROBERT F. TROXLER, of Kentucky, to be junior hospital steward. March 4, 1899.

Society Meetings for the Coming Week:

MONDAY, March 20th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, March 21st: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, March 22d: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.

THURSDAY, March 23d: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, March 24th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, March 25th: New York Medical and Surgical Society (private).

Births, Marriages, and Deaths.

Married.

GILMAN—BALDWIN. In New Haven, on Saturday, March 4th, Dr. Warren Knudsen Gilman, of Worcester, Massachusetts, and Miss Helen Harriet Baldwin.

HOYT—ACKERMAN.—In New York, on Tuesday, March 14th, Dr. Ezra P. Hoyt and Miss Maria L. Ackerman.

JOHNSON — HUNTINGTON.—In New York, on Wednesday, March 5th, Dr. Edward West Johnson and Miss Fannie Huntington.

Died.

ALLEN.—In Canarsie, N. Y., on Wednesday, March 8th, Dr. Amos Allen, of Grafton, N. Y.

BARWIS.—In New York, on Thursday, March 9th, Dr. Frank T. Barwis.

BENSON.—In Chicago, on Thursday, March 9th, Dr. John A. Benson.

BUTTS.—In Vicksburg, Mississippi, on Saturday, March 11th, Dr. John Butts, in the seventy-second year of his age.

DUNLAP.—In Indianapolis, on Tuesday, March 14th, Dr. John McDougall Dunlap, aged seventy years.

HEARD.—In Galveston, Texas, on Wednesday, March 5th, Dr. Thomas J. Heard, in the eighty-fifth year of his age.

HEATH.—In New York, on Friday, March 10th, Dr. Asahel Hawley Heath, in the seventy-sixth year of his age.

LITTLEFIELD.—In Jamestown, N. Y., on Saturday, March 11th, Dr. Joseph D. Littlefield.

OLLIPHANT.—In Mobile, on Friday, March 3d, Dr. Samuel R. Olliphant, aged seventy-one years.

PRAY.—In Brooklyn, on Thursday, March 9th, Mary B. Pray, mother of Dr. Susan R. Pray.

QUINCY.—In Boston, on Saturday, March 11th, Dr. Henry Parker Quincy.

SHATTUCK.—In Pawtucket, Rhode Island, on Saturday, March 11th, Dr. William H. Shattuck, formerly of Boston, aged seventy-seven years.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS

By ARTHUR N. TAYLOR, LL. B.

X.

RIGHTS AND LIABILITIES OF THIRD PARTIES.*

(Continued from page 347.)

Liability of Master for Attendance on Servant.—It is a well-settled doctrine that the master is not by reason of his relation to the servant liable for medical attendance upon such servant.† If, however, a physician is called by a master to attend a servant in his employ, such engagement has been held to amount to a direct undertaking by the master to pay; but if he is called by the master's wife, even with an express agreement that her husband will pay, the husband is not bound unless it can be shown that the agreement is made with his knowledge and consent, or that he subsequently ratified the hiring. The reason for this rule may be readily

perceived; the husband is never bound by the contracts of his wife except for necessities furnished to her or to her children; therefore a contract imposing a liability upon him for medical attendance upon a servant, which he is not primarily liable to pay, is beyond the scope of her authority.*

Liability of Vessels for Attendance upon Seamen.—

For the information of those physicians living in cities and towns located on the oceans, great lakes, or other navigable waters of the United States, the general rule of liability of vessels for the care and medical attendance upon their sick and disabled seamen is given.

It is a well-established rule of law that shipowners and masters are bound to provide suitable care and medical treatment for seamen who become disabled by sickness or injuries received in the discharge of their duties, and a physician attending such seamen may hold the vessel, the master, or the owners to pay for his services.‡

The extent of the period covered by this liability is the subject of much conflict; some cases hold that the seaman is entitled to care and medical treatment until he recovers, while others restrict the right to the period covered by the voyage for which the seaman is engaged. It seems that where the injury or sickness is the result of culpable negligence or mistreatment by the master or officers of the vessel the courts have held the liability to extend over the entire period of sickness or disability; whereas, when the sickness or injury could not be imputed to such cause, they have considered the liability as terminating when the voyage for which the seaman was engaged was completed and he was discharged.‡

This is a question upon which the law books present a great amount of material—some of it conflicting—but, owing to the comparatively small number of the profession who are interested in its discussion, it is not thought advisable to use the space necessary for an examination of particular instances of the application of the general principles laid down.

Statute of Frauds.—The question of when a third party not in the relation of husband, parent, or master is liable for the services of the physician is often a very nice one. Section four of the English Statute of Frauds provides, among other things, that "no action shall be brought whereby . . . to charge the defendant upon any special promise to answer for the debt, default, or miscarriage of another person . . . unless the agreement upon which such action shall be brought, or some memorandum or note thereof, shall be in writing and signed by the party to be charged therewith."

This section of the statute has been re-enacted, with certain unimportant modifications, throughout the United States.*

At first glance it would seem that in order to enforce the liability of a third person of the class we are now considering, his contract of obligation must in all cases be reduced to writing and signed. This statute is, however, not so broad in its application as it at first appears. As a matter of fact, the contract or agreement fixing the liability of the third party is more frequently without than within the operation of this statute.

* In Mr. Taylor's ninth article, published in the *Journal* for March 11th, page 347, first column, twelfth line, for "a nurse, friend, or acquaintance," read a mere friend or acquaintance; in the footnotes, for "Crane vs. Boudouine," read Crane vs. Boudouine, and for "Enlack vs. Turner," Gulack vs. Turner.

† 4 Waite's Actions and Defences, 100.

* Baker vs. Witten, 39 Pac. Rep., 491 (Ok.).

† Holt vs. Cummings, 102 Pa. St., 212; 48 Am. Rep., 199.

‡ The Ben Flint, 1 Abb. F. S., 126; the J. Fleurd, 43 Fed. Rep., 92; contra the Lizzie Frank, 31 Fed. Rep., 477.

* In Pennsylvania it does not apply to any contract the consideration of which is less than twenty dollars.

In order to bring a case within the statute, a third person who is in no way liable for the debt or default in question must promise to pay it if not paid by the debtor. If the promise is of such a nature as to act as an assignment or sale of the security for the debt, or of the debt itself to the third party, it does not come within the statute, nor if the third party assumes to be the paymaster, making himself directly and unconditionally responsible for the debt, is it necessary to reduce such agreement to writing.

It will be observed that the promise to pay must, to come within the statute, be conditional: thus, if a third party says to a physician, "If the patient does not pay you I will," the promise comes within the statute, and to be binding must be reduced to writing. But if the third party says, "Attend such a patient and I will pay you," the promise does not come within the statute, and the oral promise is binding,* for in such a case the third party does not agree to answer for the debt of another, but by his contract makes the debt his own.

It is a well-established rule of law that all valid contracts must be based upon some good or valuable consideration. If, therefore, a third party says to a physician, after the services are rendered and the indebtedness is incurred, "I will pay the bill of —," such a promise is not binding, whether written or verbal, because there is no consideration upon which to found the contract. A sufficient consideration need not be one of money. When, for example, the promise is made before services are rendered, the consideration for assuming the obligation is that the physician will render such services; or, if the services have been rendered, and a third party agrees to assume the indebtedness, provided the physician will forbear from bringing a suit upon the account, or will dismiss a suit already brought, such condition will be a sufficient consideration upon which to found the contract of liability. A physician who was attending a patient was approached by the patient's son with the following statement: "You do what you can for father, and you charge this bill to me, and what you do afterward, and I will leave you some money before I leave town." This was a direct undertaking, and therefore not required to be in writing; but, so far as it related to the fee for services already rendered, was without consideration and void, although good and binding for services rendered after the date of the promise.†

But if a physician who is attending a patient refuses to continue his services unless guaranteed that he will be paid for both past and future services, and a third party undertakes to make such payment upon condition that the physician's services shall be continued, the continuation of the services will be a sufficient consideration upon which to base the obligation.

It is hoped that the foregoing explanation has clearly shown the difference between an original undertaking, which is valid and binding whether in writing or not, and a collateral obligation for the payment of another's debt, which must be in writing to comply with the statute. An examination will therefore be made of a few cases which tend to show what circumstances will amount to a direct and original undertaking by a third party.

(To be continued.)

Letters to the Editor.

THE PRESIDENCY OF THE NEW YORK BOARD OF HEALTH.

NEW YORK, March 9, 1899.

To the Editor of the New York Medical Journal:

SIR: I inclose you herewith copy of a bill introduced in the legislature by Assemblyman Bulkley, known as assembly bill No. 1129, the enactment of which into law would remove the restriction placed on a physician being president of the health board of this city.

Why this unjust, if not unconstitutional, restriction should have been placed on the citizens who have chosen medicine as their calling nobody seems to know, nor has any one been found who could advance any good reason why the prohibition should not be repealed.

There are certainly many medical men in the city who have demonstrated that in executive ability they are not inferior to men in other walks of life. Whether these men would accept the presidency of the health board, if it were offered them, is not the question to be considered in this connection, but that they should be picked out and pointed at as incompetent to fill the position for which their education and training particularly qualify them is little short of outrageous. If a law were enacted which said that citizens who were not lawyers should be judges of our courts, or that a citizen who was not a member of a certain religious denomination should be mayor of the city of New York, thereby positively proscribing certain individuals because of their professional or religious affiliations, indignation meetings would quickly accomplish the repeal of these obnoxious laws. Why, then, should the medical men tolerate a law which places on them a penalty of this kind, simply because they are members of an otherwise honored profession?

There can be no doubt of the success of the bill repealing this unjust clause in the charter of greater New York, if the medical profession will demand it. If a sufficient number of medical men will write to their representatives in the legislature, asking that this bill receive favorable consideration, their desires will be gratified. The bill does not make it mandatory on the mayor to appoint a physician, but simply gives to medical men the right to enjoy one of the privileges the constitution gives to all citizens who are not imbeciles or convicts.

FRANK VAN FLEET, M. D.

Chairman of the Committee on Legislation of the Medical Society of the State of New York.

HOW QUININE MAY FAVOR POST PARTUM HÆMORRHAGE.

CHARLOTTESVILLE, VA., March 1, 1899.

To the Editor of the New York Medical Journal:

SIR: Dr. Barton C. Hirst, in his article in the *American Text-book of Obstetrics*, mentions that quinine given as an oxytocic increases the liability to post-partum hemorrhage, but offers no explanation as to why it should have this effect. It is well known that the presence of white blood corpuscles is essential to the formation of a blood clot. Possibly this liability to post-partum hemorrhage after the administration of quinine is due to the fact that quinine interferes with the activity of the white blood corpuscles, and, if given in sufficient quantities, may do so to such an extent that the coagulation of the blood in the uterine vessels after labor is imperfect.

H. D. FERNISS, M. D.

Book Notices.

Traumatic Separation of the Epiphyses. By JOHN POLAND, F. R. C. S., with Three Hundred and Thirty-seven Illustrations and Skiagrams. London: Smith, Elder, and Company, New York: G. P. Putnam's Sons, 1898. Pp. xxxi-926. [Price, \$18.]

It would seem on first thought that a book of over nine hundred pages on the single subject of separation of the epiphyses must necessarily contain a great deal of superfluous matter. But we believe the standpoint of the author to be a just one, that this condition has hitherto been imperfectly dealt with in the standard works on surgery and orthopedics, and that one is justified in laying stress on the development of bone, pathological anatomy, etc., in an exhaustive book of this kind. Several pages even are devoted to experiments on lower animals and on the dead subject to bring about this condition. The reader will find elaborate statistics relating to its frequency as regards age, sex, etc. The total number of cases collected of the long bones is six hundred and ninety-three. The order of frequency is as follows: 1. The lower epiphysis of the femur. 2. The lower epiphysis of the radius. 3. The upper epiphysis of the humerus. 4. The lower epiphysis of the humerus. 5. The lower epiphysis of the tibia. 6. The upper epiphysis of the tibia. The question whether separation of the epiphysis can occur during intra-uterine life receives only a passing notice, the author apparently not having seen the condition. It is a subject, however, of importance from a medico-legal standpoint, since not infrequently is this condition present in the newly born, and it is important to determine whether it occurred during the labor or was present before.

Foucher divides separation of the epiphysis into three classes: 1. Pure separation of the epiphysis from the diaphysis without any osseous tissue adhering to it. 2. Separation of the epiphysis with a thin, finely granular layer of osseous material attached to it. 3. Solution of continuity of the diaphysis in the midst of the osseous spongy tissue near the epiphysis. In instances in which this occurs ossification is fairly well advanced, the epiphysis being almost joined to the diaphysis. It must be admitted, though, as the author suggests, that true separation or a clean separation between the osseous tissue and the epiphyseal cartilage is extremely rare. To the average reader many of the lesions described will appear but as curiosities. The Röntgen pictures are numerous, and show extremely well what they are intended to represent.

Die Einschränkung des Bauchschnitts durch die vaginale Laparotomie (Kolpoceliotomie anterior). Von Professor Dr. A. DÜHRSEN, in Berlin. Mit 7 Abbildungen und 6 Tabellen. Berlin: S. Karger, 1899. Pp. 266.

SINCE the theoretical suggestion by Sänger of the availability of the anterior transverse incision of the vagina in the reposition and suturing of a retroverted uterus and the practical carrying out of the method by Dührsen, the latter operator has had a vast experience, the results of which are given in the monograph under consideration. The actual motive seems to be not so

much the detailing of statistics as to remove the just stigma which the operation has received because of the great danger from pregnancy ensuing after its performance. A number of cases have been reported in which, after fixation of the uterus by this method, it has been necessary to do a laparotomy and remove the child by the abdomen, with fatal results in some cases. This is caused, in the author's opinion, by the formation of firm fibrous adhesions between the anterior surface of the uterus and the posterior surface of the bladder. The adhesions so formed are not distensible during the enlargement of the gravid uterus and lead to difficulties during delivery, all of which can be avoided by proper suture of the peritoneum, so that the adhesions which are to hold the uterus in place may be solely between the two peritoneal surfaces. Such adhesions are easily stretched during the enlargement of the uterus in pregnancy. Complete tables of the author's five hundred and three cases of anterior colpoceliotomy are furnished, together with a special one detailing the results of pregnancies after such an operation. The figures seem to sustain the thesis very well, but final judgment must be deferred until there are more cases at our disposal.

Affections chirurgicales du tronc—statistique et observations. Par le Dr. POLAILLON, Chirurgien de l'Hôtel-Dieu, Professeur agrégé à la Faculté de médecine de Paris, etc. Paris: Octave Doyn, 1898. Pp. vi-843.

THIS volume contains the reports of the cases of surgical diseases of the chest and abdomen, including those of the male genito-urinary tract, which were observed by the author during a period of nearly twenty years. The peculiar value of the publication lies in the fact that all cases of any interest have been fully recorded, while the less valuable ones are included in the statistics, and also in the fact that the results extend over a period beginning with the use of the spray and antiseptics of Lister and ending with the present era of asepsis. There is a moderate number of illustrations, chiefly diagrammatic, but all showing the essential points of the conditions to be recorded. Such a work is a valuable storehouse of surgical knowledge and should be a stimulus to inspire similar full and careful reports in this country.

Chirurgie de l'utérus. Par HENRI DELAGÈNIÈRE, Ancien interne en chirurgie des hôpitaux de Paris, etc. Avec 378 figures dans le texte. Paris: Institut de bibliographie scientifique, 1898. Pp. xii-467.

THIS is a most useful compilation of the multitudinous operations which at one time or another have been invented and carried out upon the uterus. The procedures are arranged in chronological order in each section, and an excellent index renders the finding of the description of any desired operation but the matter of a few moments.

BOOKS, ETC., RECEIVED.

Examination of Water. (Chemical and Bacteriological.) By William P. Mason, Professor of Chemistry, Reusselair Polytechnic Institute, etc. First Edition. First Thousand. New York: John Wiley & Sons, 1899. Pp. 135.

The Ready Reference Handbook of Diseases of the Skin. By George Thomas Jackson, M. D. (Col.), Pro-

fessor of Dermatology in the Woman's Medical College of the New York Infirmary and in the Medical Department of the University of Vermont, etc. With Seventy-five Illustrations. Third Edition, revised and enlarged. Lea Brothers, 1899. New York and Philadelphia: Pp. viii-17 to 647. [Price, \$2.50.]

Les rayons de Röntgen et le diagnostic de la tuberculose. Par A. Bécère, Médecin de l'Hôpital Sainte-Anthoine. Avec 9 figures dans le texte. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 95.

De la diminution de l'activité nerveuse dans le psoriasis, le cancer et la lèpre. Disparition de ce syndrome sous l'influence du traitement par les injections organiques. Avec 20 gravures dans le texte et 2 tableaux donnant les rapports d'échanges nutritifs ou urologiques et les schémas urographiques fournis par l'analyse. Communication à l'Académie de médecine par le Docteur Bouffe, Membre de la Société de médecine et de chirurgie pratiques de Paris, etc. Paris: A. Maloine, 1899.

New Inventions, etc

A NEW SURGICAL TABLE.

By JONAS S. FORD, M.D., H.B.

TRACTION TABLE.

This illustration needs no explanation, and will give some definite idea of a surgical table as planned and constructed, in view of interesting geometrical and practical and new lines of thought. I hardly say that the invention, as it now appears, is not a hundred at all perfect, and I

were I to reconstruct the present table, I would make many alterations. Some attachments I believe to be superfluous and without advantage, but, in the main, I am satisfied, and will now endeavor to acquaint the

FIG. 1a.

profession with the device and the ideas which led to its construction. To aid us, the reader will be frequently required to consult the illustrations, but as a prelude I may with advantage outline the fundamental ideas from which the table was developed. 1. Experience taught me that heat, generously applied to the body of a patient undergoing a severe surgical operation, sustained the forces and acted as a great preventive of shock. 2. Ether, being evaporated by heat and supplied with oxygen, is less unpleasant to inhale, the anaesthesia being more rapid, and vomiting, under ordinary care, seldom witnessed. All this is of advantage in preserving the tranquility of the nervous system, thereby diminishing the liability to shock, and substituting pleasant for, as a rule, extremely unpleasant experiences. 3. The need of an adjustable flexible sawing, milling, and drilling cable arranged for horizontal and circular movements will be appreciated in all those operations upon bone where high speed and a powerful cutting tool are a requisite. 4. A capacious aspirating outfit, always in readiness and accessible, is desirable. 5. The discharge of hot, cold, and tepid distilled water, and the choice of two or more antiseptic solutions through a single common conduit by a simple opening and closing of valves—the same to be by a separate branch tube joined to the aspirating tube—is believed to be of the greatest advantage. 6. A forced respiratory apparatus, operating upon the anæsthetic vapor chamber, making it possible to continue anaesthesia and artificial respiration at the same time, is of first importance in clearing the way for those successful operations requiring pulmonary relaxation. 7. Ligature chambers, tray chambers, storage chambers, and receptacles for dressings, may be the subject of various and useful elaborations. Some will understand the importance of many of these details, and will appreciate the necessity of having the leading components operating in a harmonious and logical use. The table, as it now appears, is a mechanical structure, and the details of its construction can be better understood by referring to the illustrations than by any verbal description. Some of the details of the table are shown moved upon the table, and the table is shown moved into the position of use. The table is shown in two positions, one for use with the patient lying on the table, and the other for use with the patient lying on the floor.

The advantage of such an arrangement for supplying heat to a patient undergoing a severe surgical operation need not be dwelt upon, as it will be apparent; the only additional requirement necessary to mention is the use of a sufficient number of woolen blankets, folded and laid upon the steam-heated surface, to be again covered with a rubber sheet for the purpose of preventing the moisture of the patient's body from penetrating to the heated sections. This is a precautionary measure to be observed. The above view, also, shows the hollow sections hinged to the upper tie bars which support suitable bearings for a rotary shaft on either side of the table, the shafts being represented, one of which bears the mechanical device for giving rotary motion to the adjustable flexible drilling cable. The horizontal rotary shafts are driven by an electric motor concealed within the table.

Regarding the top of the table, another feature to be especially noticed is the manner of raising and lowering the Trendelenburg section. This

Fig. 3a.

is accomplished by means of two double-threaded high-pitched screws pivoted to the movable section and moved upward and downward by revolving nuts, held within

on the pivoted shafts of the thimbles containing the revolving nuts, each corresponding bevel-gear wheel being

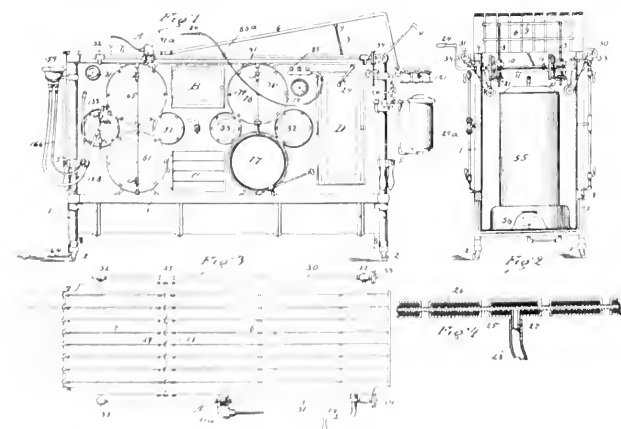

Fig. 5.

supplied with a small spur-gear wheel, which meshes with a large spur-gear wheel pinioned to the cross shaft and operated by a crank shaft shown in Figs. 1 and 2, No. 24.

The advantage of this manner of elevating the top of the table is that it does away with ratchets, and will remain immovable at any point of desirable elevation. The crank may be removed and sterilized at pleasure. Fig. 4 shows a cross section of the hollow bars composing the table top on line with the steam-supply tube represented also in Fig. 3, No. 25. In Fig. 4, No. 28, the flexible steam hose is shown attached. In Fig. 2 a boiler, No. 55, is shown as the source of steam supply; but it should be remembered that this is not necessary where any other steam supply is accessible. In Fig. 1, No. 83a, the flexible aspirating tube, supplied with cannula, is represented attached to a cannulated block, guarded by triple valves, illustrated in Fig. 10. Nos. 82 and 83, in Fig. 1, are aspirating reservoirs; Nos. 76 and 77 are sterilizers; *B* and *C* are tray cabinets; No. 57, a gasoline tank; No. 65, a cold-water reservoir; No. 61, a hot-water reservoir; No. 132, an etherizing apparatus; No. 127, receptacle for dressings; No. 121, ligature chambers, each and all of which are connected with the steam supply of the table. Fig. 5 shows all the receptacles with their connecting tubes and valves. It might be mentioned here that reservoirs Nos. 61 and 65 are connected with an air pump for the purpose of securing air pressure to force the fluids into a single common flexible tube for irrigating purposes. The scheme is to supply all parts with air, steam, and water, thereby making it possible to sterilize, wash, and supply needed pressure.

Fig. 7 shows the upper tie bars and a view of the interior of the table when the hinged sections removed. This illustration shows the gear wheels, their connections and relations, the different journals, and the reservoir connecting tubes, with their valves; also the two

providing the table each of the revolving nut bearing upon the end of a bevel gear wheel, which bevel gear wheel meshes with a corresponding bevel gear wheel journaled

large wash bottles, Nos. 107 and 108, for antiseptic solutions connected on one side of the table with the common irrigator, and on the other with the aspirating

either side of the table, and is easily removed for that purpose or that of sterilization. Fig. 12 represents the chuck for holding a drill, saw, or milling tool. Figs. 17

apparatus. Fig. 8 shows the arrangement of the gear wheels used to operate the adjustable flexible shaft. Fig. 9 shows the same in their respective housings; and in Fig. 7, No. 51a, the device is represented in its proper

place on the horizontal shaft, where it can be moved along the shaft to any point and turned to any angle suitable for the operator. It is constructed for use on

when it is applied to a patient with the forced respiratory pumps in operation, artificial respiration is thereby conducted, and is regulated by the exchange of air occupying the space between the metallic wall of the receptacle, No. 132, and sac, No. 136. This, as will be seen, imitates the normal respiratory operation, and makes it possible to continue anesthesia at the same time. Should air be desirable instead of the anesthetic vapor, cap No. 154, opening tube No. 156, should be removed. This allows a stream of fresh air to pour into the ether sac, and may be substituted in artificial respiration for that of the anesthetic vapor.

Commenting upon the table, which, through fear of wearying the reader, I have just barely outlined, the features which deserve most attention are those relating to the warming of the patient, the side shaft with adjustable flexible cable, the hot-ether combination, the aspirating outfit, and the method of raising and lowering the Trendelenburg section. These are so valuable that I can not insist too much upon their importance. I have made frequent use of the table since its completion, and experience satisfies me that a new and rich field is under way of development. Patients undergo severe surgical operations on this table without the slightest break in their normal condition. I have experienced the beneficial effects too often not to know their proper valuation. Rarely do patients vomit from the inhalation of the warm ether, and they express themselves as being free from any nausea or sickness, and are perfectly willing to repeat the experience, if required. In leaving the subject, I desire to express the wish that the principles herein discussed may find their general use.

2123 ASHLAND AVENUE

MISCELLANY

Remarkable Instances of the Value of Suggestion in Therapeutics. In a paper read before the American Society for the Study of Suggestion at the University of Chicago, Dr. J. H. Crook, of the University of Chicago, presented the following cases:

fore the New South Wales Branch of the British Medical Association, the Hon. J. M. Creed, member of the Legislative Council, M. R. C. S. and L. R. C. P., Edinburgh (*Australasian Medical Gazette*, January 20th), said:

"I may, perhaps, best at this stage call your attention to a condition which I have been able to produce in a considerable number of subjects, and which I have not found described by other operators.

"It is so very remarkable that I have asked two gentlemen who are now present, both highly intelligent men, possessing more than average business knowledge and common sense, to permit me to show you by demonstration exactly what it is. They are both good hypnotic subjects, one of whom suffered from neuralgia, from which hypnotism quickly relieved him after somewhat prolonged suffering, the other having been persistently the victim of insomnia; he, prior to his being hypnotized, often remaining awake almost the whole night for days together.

"Since the first time I hypnotized the latter he has never for a single hour suffered in this way. Both of them are able to do as follows: On making use, either in my presence or when I am absent, of the arranged signal, which in the one is placing the forefinger of the left hand on the lips, in the other inserting the tip of either thumb between them, they instantly set up this extraordinary condition.

"To the bystanding observer there is no apparent change; the converse, go on with their occupation, and do everything just as if nothing had taken place; but in spite of all this they have, on using the signal, ceased to be sensible to pain. Nothing hurts them, and they can submit to being pricked, pinched, or otherwise maltreated without the slightest feeling. This you can test yourselves, for my patients, though, as you perceive, quite conscious of everything going on, will have no discomfort as the result of your efforts to hurt them. Nor are they only insensible to pain arising from injury inflicted while they are in this condition, but if at any time they have any, whether arising from accident or consequent on the morbid condition of any part (for instance, in toothache or neuralgia), by making use of the signal it ceases instantly.*

"As a case in point, Mr. H. could, and if you wish it, will tell you how, when a considerable quantity of molten and flaming 'Chatterton's compound,' the melting point of which is very much higher than that of sealing wax, fell upon his hand, the torture from which would, under ordinary conditions, have been both lasting and intense, and which had actually commenced, he by making use of the arranged signal never for one moment felt the slightest discomfort from it. I did not see him until a week after the accident, when he showed me a deep wound from which the eschar had separated. A more crucial test than this it would be difficult to conceive, and yet he assures me that from the moment he touched his lips with his left forefinger he suffered no further pain. Some time after this he came to consult me, having accidentally torn his hand to an extent which necessitated the insertion of several stitches after antiseptic cleansing. He made use of

his signal, and I did all that was necessary without his having a disagreeable sensation. He held his hand in any position I required, and assisted me in what I was doing, chatting all the time, being as interested and as little inconvenienced as if the little operation was being done on some one else. How long this condition would continue if left unchanged it is difficult to say, for I give my subjects the power to restore sensibility by another signal. I do this because, without the safeguard of pain, they might seriously injure themselves, and yet be unconscious of the occurrence. I would, however, point out that, though the power to feel pain from a fresh cause is restored, that which has been removed in this way does not return."

These cases are enough to prove to any thinking person that whatever genuine results are attained by Christian Science methods are attributable simply and solely to suggestion. The author further says:

"In my opinion, even in those instances in which recovery takes place under the exhibition of the remedies of the pharmacopoeia, success has frequently been the result of suggestion, unconscious on the part of both doctor and patient. In support of this view, I would ask you to call to your minds the success which often attends one practitioner in the use of drugs practically identical with those previously used by another one in a similar or even in the same case. But one inference can fairly be drawn from this—viz., that the former is able readily to enforce a feeling of confidence in the patient, and so more forcibly suggests that obedience to the instructions given will result in rapid recovery."

Exactly so. And it is by its claim to be based upon religion that Christian Science succeeds in establishing that feeling of confidence so necessary to make the patient susceptible to suggestion.

Errata.—In Dr. J. P. Crozer Griffith's article on *The Weight in the First Two Years of Life*, published in our issue for March 4th, two errors occurred. Chart III should have been omitted, and in the text, page 294, first column, beginning in the fifth line, the sentence "Camerer also gives some estimations of the rate of growth during the second year (see Chart III)," for "Chart III" read Chart II.

The New York Academy of Medicine.—At a stated meeting, on Thursday evening, the discussion on syphilis was continued, during which the following papers were presented: *Some Surgical Aspects of Syphilis*, by Dr. Frank Hartley; *Syphilitic Dementia and Paretic Dementia*, and *The Treatment of Syphilis of the Nervous System*, by Dr. C. K. Mills, of Philadelphia; *The General Diagnosis of Brain and Spinal-cord Syphilis*, by Dr. B. Sachs; *The Ophthalmological Aspects of Syphilis*, by Dr. C. S. Bull; and *Syphilitic Affections of the Respiratory Passages*, by Dr. Francke H. Bosworth.

At the next meeting of the Section in Ophthalmology and Otolaryngology, on Monday evening, the 20th inst., the following papers will be read: *Clinical Experience with the Large (Helm's) Magnet*, by Dr. H. Knapp; *Restoration of the Conjunctival Cul-de-sac by Means of Thiersch Skin Grafts*, by Dr. Charles H. May; and *The Use of the Extract of the Supratarsal Capsule in Diseases of the Eye*, by Dr. W. H. Bates. Dr. W. M. Leszynsky will present a case of acromegaly and Dr. H. Knapp will present a case of traumatic cataract and iris cyst.

At the next meeting of the Section in General Medi-

*The following footnote by the editor appears in the *Gazette*: "The subject when resuscitated produced the condition described, which was thought to be by the member present, who found that, though completely conscious and in possession of the fullest mental acuteness, he was quite insensible to pain."—*Ed. J. M. G.*"

cine, on Tuesday evening, the 21st inst., the following papers will be presented: A Case of Spinal Disease presenting Unusual Symptoms, by Dr. W. M. Leszynsky; Observations on the Treatment of Hay Fever: The Past Season; the Classification of Cases with and without Nasal Lesion; Cases of the Second Class; the Treatment of Cause, Attack, General Symptoms, and Inter-current Period; the Treatment by the Suprarenal Gland, by Dr. Beaman Douglass; and Atypical Forms of Pneumonia; a Clinical Account of a Hundred Cases with a Consideration of Gastric, Cerebral, Wandering, Abortive, Masked, and Chronic Pneumonia, by Dr. Emil Palier.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday, March 22d, Dr. Thomas J. Harris will read a paper on Sarcoma of the Nose, with a Report of Five Cases. Cases will be presented and new instruments, apparatus, and specimens will be exhibited.

At the next meeting of the Section in Obstetrics and Gynaecology, on Thursday evening, the 23d inst., Dr. A. F. Currier will read a paper on Tuberculous Peritonitis, and there will be a general discussion on puerperal infection. Dr. J. A. Schmitt will present specimens of uterine and ovarian tumors, and Dr. H. N. Vineberg will present an ovarian cyst with twisted pedicle and a hairpin removed from the bladder through Kelly's cystoscope.

At the next meeting of the Section in Neurology and Psychiatry, on Friday evening, the 24th inst., the following papers will be read: Jacksonian Epilepsy, with a Report of a Case Four Years after Operation, by Dr. G. M. Hammond; A Case of Facial Hemihypertrophy, by Dr. I. J. Walsh; and Hysteria in Childhood, by Dr. B. Sachs.

The Role of the Prevention of Conception.—According to the *Cleveland Medical Gazette* for February, citing the *Medical News*, *Troub* (*Centralblatt für Gynäkologie*, October 15, 1898) says that the principle, "No medical treatment without medical indication," does not meet all cases. Cosmetic operations are certainly justifiable. Not less so is the proper application of the *pessarium ocluserium*. This means of preventing conception is absolutely without danger. The danger for nervous persons lies rather in interrupted coitus and in the use of condoms. It is the duty of the physician to warn phthisical, epileptic, and neurotic persons that they ought not to have children. If a physician refuses, on account of Biblical or Talmudic law, to furnish to such persons the knowledge necessary to prevent conception, there is an end of medical scientific treatment. The significance of normal cohabitation is in general far too little considered. In men as well as animals the longing for coitus is not always associated with the desire for offspring, so that it is not right to speak of sterile intercourse as something contrary to Nature. Complete sexual abstinence is capable of working injury, if the attempts to overcome the desire for it put the physical and psychical powers of the individual to too great a strain. Voluntary sterility is allowable when the increase in the number of children would make it impossible that all should be properly brought up, or when the wife is not in physical condition to bear children. Preventive measures are abused by the rich, but they are too little used by the poor.

The Mississippi Valley Medical Association.—The twenty-fifth annual meeting will be held in Chicago

Tuesday, Wednesday, Thursday, and Friday, September 12th, 13th, 14th, and 15th, under the presidency of Dr. Duncan Eve, of Nashville. The secretary remarks that it has been some twelve years since Chicago entertained a medical body of national importance, and the profession of the city, under the chairmanship of Dr. Harold N. Moyer, is determined that this shall be a notable gathering in every respect. The committee of arrangements has in preparation a handsome souvenir booklet, containing a history of medical Chicago, which will also be the programme of the meeting. In honor of the association there will be given, before and after the meeting, a series of clinics at the various colleges and hospitals, a full description of which will be contained in the booklet referred to. Admirable arrangements have been made by the local committee for the places of meeting, both for the general sessions and for the medical and surgical sections. The rooms of the Chicago Medical Society, which will be the headquarters before and after the meeting for those who avail themselves of the clinics offered, and the Columbus Medical Library are very close to the place of meeting. The annual addresses in medicine and surgery will be notable. Particulars will be announced at a later date. In order that a place may be secured on the programme, titles of papers should be sent early to Dr. Henry E. Tuley, the secretary, Louisville, Ky.

The Northwestern University Woman's Medical School, of Chicago.—Dr. Marie J. Mergler has been elected dean, in place of Dr. I. N. Danforth, resigned. Dr. Danforth has been elected dean emeritus. The yearly course has been changed from one of two terms to one of four terms of twelve weeks each, beginning respectively on the 1st of July, October, January, and April. Three terms will be required; the other term will be optional. The number of regular students will be limited to a hundred, twenty-five in each class. They will be admitted to competitive examination for place in the class only after having complied with the requirements of the State board of health.

The International Medical Magazine.—We are informed that the *International Medical Magazine*, formerly published in Philadelphia, has been taken over by E. B. Treat & Co., of West Twenty-third Street, New York. Dr. Boardman Reed continues in his position as editor.

The Independent Medical College of Chicago Scotched.—According to the *Medical News* for March 1th, diplomas issued by this college have been recently declared illegal, and the charter of this institution revoked. Is the snake killed or only scotched? And if killed, will it prove a phoxix?

Anginal Attacks in Writers.—Macgrave's *Science of Medicine*, January 25th; *Independent Medical Magazine*, February 23d) describes a particular form of angina associated with the act of writing hurriedly, and only occurring under those circumstances. The cases are as follows: A person having to accomplish in a few minutes a great deal of time an important correspondence, was obliged to the task of writing letters on the subject of the day already seized with a severe pain behind the sternum. He became open to the attack, although his heart was on the point of being attacked. He experienced palpitations. The pain was very severe. If backward, when the crisis appeared, the writer again devoted himself to the task. The attack subsided, the

author says, are due to the position of the body in the course of work, added to the nervous superexcitation. In the attitude assumed when writing hastily the respiration becomes retarded, the expansion of the diaphragm becoming impeded by the compression undergone by the abdomen. Moreover, there is a kind of spasmodic contraction of the fingers which is communicated to the muscles of the forearm, the arm, and the thorax. The action of the heart is trammelled, especially as regards the right ventricle, which results in a certain degree of venous stasis, provoking a spasm of the coronary vessels that results in an angular attack.

A Convenient Way to Give a Vaginal Douche.—Dr. V. R. Pennock (*Colorado Medical Journal*, February) says that in ordering a vaginal douche it is very easy for us to inform our patient that she should use two or more gallons of a certain solution, instruct her as to the kind of a nozzle to use, the height of the reservoir, and to lie always upon her back. This last direction she is very apt not to follow unless taught a method more convenient than using old rags to collect the return flow.

He has used the following method for a few years and finds it convenient for douches, even after curetting at the patient's home:

An ordinary straight-backed chair is tipped forward with its top over the middle of a washtub. The chair in this position is covered with pillows and the patient places herself upon it, with feet on the edge of the tub and hips over its middle, supported by the back of the chair. There is no soiling of garments or bedding and the apparatus can be found in every home.

"How it's done" in Electricity.—"A certain physician," says the *Criterion* (*Electrical Review*, February 1st), "had a large Toepler-Holtz machine which gave a spark like a young streak of lightning. His wife was much interested in it and watched the doctor manipulate it until she fancied herself master of the apparatus. One day a party of friends called when the doctor was out, and the good wife seized the opportunity of paralyzing them with her knowledge of science. She was a very dignified woman of portly presence, and after leading them into the office, she began her explanation with all the impressiveness of a lecturer. She spoke briefly of the preliminary manipulation of the machine. 'And, then,' she said, laying her hand upon one connection, 'the electricity goes from here to here,' whereupon an angry white spark leaped out from the brass ball indicated, with a report like a horse pistol, and smote her upon the extended finger, causing her to sit upon the floor with a violence that shook the window panes. The guests stood around in expectant attitudes, looking at their fallen hostess in pardonable surprise. Only for a moment did that capable woman leave them in doubt: 'There,' said she, in the most matter-of-fact manner, as though events had simply followed the usual course, 'you see how it works. Now, let's go into the garden and look at the chrysanthemums.'"

The Fallacies that Beset Amateur Doctoring.—According to the *Boston Medical and Surgical Journal* for February 23d, a writer in the *Westminster Review* for January, 1899, p. 71, strongly sets forth the fallacies and mischief of amateur medicine. Failures to make the distinction between symptoms and diseases or between the different stages or degrees of a disease, or to note peculiarities of constitution, are sufficiently obvious

pitfalls. The syllogism employed is something like this: "My friend had a headache and was cured by iron; I have a headache, therefore I shall be cured by iron." But headache is not a disease; it is a symptom, and occurs in a large number of diseases, of which hyperæmia of the cerebrum and anæmia thereof may be taken as examples. When the name of the disease is substituted for that of the symptom the syllogism becomes nonsense, thus: "My friend had anæmia and was cured by iron; I have hyperæmia of the brain and, therefore, shall be cured by iron."

Another Case of Double Ovariectomy during Pregnancy.—Dr. R. A. Kingman (*Boston Medical and Surgical Journal*, February 23d) records a second case of double ovariectomy during pregnancy, in this instance there being a hydatidiform mole. In the same journal for July 29, 1897, Dr. Kingman reported a first case of double ovariectomy during pregnancy, in which case two abdominal tumors of considerable size were removed and the pregnancy went on to term. Dr. Kingman remarks upon his present case as follows:

"This case presents points of interest both for the gynecologist and the obstetrician. Both will note at once the difficulty presented in attempting an accurate diagnosis, owing chiefly to the change from the customary signs of pregnancy, due to the presence of a mole rather than a living embryo in the uterus. The rapid enlargement which takes place in such cases, commonly about the third month, had already caused marked thinning of the uterine wall, and the shape of the tumor was strongly ovoid instead of spherical as in ordinary pregnancy. From the gynecological standpoint, I would particularly call attention to the striking absence of vascularity in the pedicle as contrasted with the case before reported. In that report I said: 'The only unusual condition noted in consequence of the pregnancy was the extreme vascularity of the pedicle, which consisted of the whole breadth of the broad ligament. It seemed a mass of dilated, tortuous veins.' The explanation of this difference must be found in the fact that the uterus did not contain a living ovum, and Nature had therefore failed to provide for a continuance of development. A point noted before is again emphasized by the occurrence of pregnancy in such an advanced stage of disease of the ovaries. There seemed no true ovarian tissue left, and yet an ovule was brought to maturity and impregnation resulted, for it is an accepted fact that hydatidiform mole can not occur without conception. Here, however, our knowledge of the etiology of this condition seems to be at an end, and in this connection this case assumes its greatest interest to the obstetrician. In view of the rarity of the disease, this is probably the only case on record in which the inside of the abdomen and pelvis have been observed during its continuance and in the living subject. True, the case reveals no conclusive evidence upon which to build a theory, but it at least suggests the possibility that the advanced disease of the ovaries may be responsible for a lessened vitality in the ovum, hence leading to the disease of the chorion and the death of the fetus. The prompt delivery after the operation can not be attributed to the latter, as hemorrhage had begun the day before and expulsion of the mass could not long have been delayed."

A Possible Danger of Artificial Respiration.—M. Brosch, of Vienna, while making experiments on the

cadaver, noted a possible danger of artificial respiration, which was recorded in the *Progrès médical* for September 24, 1898, p. 213. In the issue of the same journal for January 28, 1899, Dr. R. S. Stewart records a case which emphasizes this danger. A patient in the Glamorgan County Asylum, Wales, forty years of age, the victim of mania of seven years' duration, had to be fed by an attendant, not from any difficulty of swallowing, but because of his violence. On December 17th there was served to him a supper composed of bread soaked in milk and well pulped, in quantity a little less than a pint. The entire amount was administered without any difficulty, and without any indication that the food had taken any unusual course. After some moments, and without any warning, the patient's head fell back and he became pale as death, displaying neither pulsation nor respiration. Immediately the attendant placed him in the recumbent position and began artificial respiration after Sylvester's method. Some minutes later the physicians found an entire absence of either pulsation or respiration, and were unable to discover any cardiac action. The mouth and pharynx were perfectly empty. The attendant observed three or four light respirations after the syncopal attack. The autopsy was made seventeen hours after death. There was *rigor mortis*, and the entire surface of the body was of a pronounced pallor and not at all livid. The brain was atrophied and oedematous, the meninges thickened, opalescent, and half full of fluid, but there were no adhesions. The cerebro-spinal fluid was in excess, but no gross lesion was discoverable. The pericardium contained nearly a centilitre of transparent fluid. The heart, which weighed three hundred and twenty-five grammes, was soft and flaccid; the auricles half full of fluid and dark-colored blood; the ventricles empty, with the exception of a small clot, somewhat dense, half pallid and half dark-colored, which was found in the muscular recesses of the lower portion of the right ventricle. There was advanced atheroma round the orifices of the coronary arteries and on the inner surface of the ascending aorta to the extent of five centimetres. The left lung weighed about five hundred and sixty grammes and the right lung five hundred and ninety grammes. There were no adhesions, and the surface was perfectly normal in appearance. On examination, food *débris* was found in each bronchus, and incision of the lungs showed similar *débris* in the smallest bronchioles, especially in the lower lobes. In other respects there was nothing abnormal save a slight congestion of the posterior and lower parts. There were no foreign bodies either in the mouth or pharynx, but in the upper part of the trachea was found a very small quantity of pulped aliment. The stomach contained about five centilitres of food, and the lining membrane was in every respect normal.

In this case death evidently resulted from sudden heart failure, which often occurs when the coronary arteries are degenerated at their origin, and it had no relation to any interference with respiration. There were no signs of asphyxiation. At the moment of the syncopal attack the stomach contained a pint of aliment; at the autopsy there remained only a tenth of this amount. It is impossible that what had disappeared from the stomach should have entered the lungs, for they were not in excess of their normal weight; a considerable portion must therefore have passed by the pyloric orifice into the intestine. The matter found in the lungs evidently came from the stomach, from which it would appear that the cardiac orifice of the stomach

can easily be forced, at any rate in the cadaver, and its contents be passed along the oesophagus up to the pharynx by the compression of the lower part of the thorax (the usual method of expression of air from the lungs) and inspired in the ordinary way at each successive artificial inspiration. It is not certain that the contents of the stomach can under similar circumstances pass with equal facility into the lungs of a living subject without his cognizance, but if it should be so, then the danger is a very real one. In the present case, if by any chance the syncope had not been instantly fatal, recovery would have been scarcely probable, for death by asphyxia would have ensued. Consequently, in all cases of suspended respiration, if there is reason to suspect that the stomach contains nourishment or any liquid whatsoever, it is requisite to empty it by means of the tube if possible. If this is not possible, Sylvester's, Marshall Hall's, or Howard's method of artificial respiration should be avoided, and efforts should be made to reestablish breathing by rhythmic traction of the tongue. That is the only method of avoiding asphyxiation by the passage of foreign bodies from the stomach into the respiratory passages.

The Treacherous Lulls of Appendicitis.—Professor Dieulafoy (*Presse médicale*, February 8th) thus concludes a paper on the Deceptive Lulls of Appendicitis: 1. The marked and painful symptoms of appendicitis, the vomiting and the fever, are often followed by an abrupt lull with disappearance of the pain, fall of the fever, and a general sense of relief to the patient. 2. This abrupt lull, this deferescence, is not always the sign of a real amelioration; it is often false, deceptive, and treacherous. 3. It must further be remarked that this misleading and treacherous lull often coincides with the formation of most dangerous lesions, gangrene of the appendix, peritoneal septicæmia, and diffuse peritonitis. 4. The treacherous lull is never a complete lull. Regarded closely, it is seen to differ from a real amelioration by the persistence of some symptoms. In the case of an apparent calm the abdomen remains more or less tympanitic, the muscular resistance does not always disappear, the amelioration of the pulse persists, even though the temperature may have fallen, and urobilinuria and albuminuria are not rare. 5. This false retreat in appendicitis is sometimes favored by medication, injections of morphia, the application of ice-bags, etc., which mask the evolution of dangerous symptoms. 6. It appears at variable intervals, as shown by the author's observations. 7. The lulls coinciding with the development of the gravest peritoneal lesions show, moreover, the inexactness of the descriptions which distinguish by well-marked lines appendicitis from peritonitis. Such descriptions perpetuate fatal errors; frequently the symptoms of appendicitis and of peritonitis are similar, concurrent, and mixed, so that it is impossible to decide at what moment peritonitis sets in. 8. These treacherous lulls in appendicitis are the most frequent cause of death. A physician or surgeon of too hesitating a character eagerly seeks upon this apparent lull in the disease to adjourn or avoid any intervention, believing that there will always be time to operate at leisure later; but meanwhile the disease advances interference, against which surgical means are powerless, and the patient succumbs. 9. We must, then, distrust these treacherous lulls of appendicitis, and learn to recognize them, and operate without delay, for we would not expose our patients to the risk of death.

The Ideal Doctor—Genius, Philosopher, and Lover of Goodness.—The Syracuse Professional Women's League recently held a banquet at which Dr. Anna Manning Comfort was to speak to this toast. She was unable to be present, but she dictated the following response, which was read by another woman physician:

The long-accepted custom and maxim that "the brethren embrace the sisters" seems so firmly established as to almost defy uprooting. For, whenever and wherever women are co-workers with men, all generalizations bearing upon them are expressed through the masculine pronoun "he," but, since women have become an all-embracing sisterhood, why should we not, with *fin-de-siècle* progress, institute a reversal of this usage, and thus prove to our brothers that we can be as gallant and all-inclusive as they? Highly improper as it is deemed to thus embrace the men, I will boldly venture the innovation for this once, begging the protection of my professional sisters, and will proceed to portray the "ideal physician," under the feminine pronoun "she."

"The ideal physician—genius, philosopher, and lover of goodness." Extravagant as some of these qualifications at first appear, they are not so in fact. For what, if you please, is not expected of the ideal physician? First, general scholarship; next, specific preparation and high attainments, with experience and skill. But, superadded to this, there must be a marked personality, a strong body, a vigorous mind with extraordinary individuality of character. Aye, indeed, if she is all that the world expects of her, she is in truth a genius.

Her life must be absolutely unselfish, while she must possess every positive and negative virtue known to the human family. Ever alert, ardent, and tireless, she must respond to suffering's call, ready on the instant to diagnose, prognosticate, and treat anything and everything, from a simulated or threatening ailment to the last throes of physical agony. She must quickly and accurately define the meaning of ill-defined or half-expressed symptoms, as met with in the infant, deaf-mute, idiot, or inebriate, in states of cerebral stupefaction or delirious excitement, such as apoplexy, epilepsy, hysteria, insanity, syncope, special injuries, or toxic action of drugs. For all this, the ideal physician must possess keen, intuitive perception, no less than specific medical knowledge. She must be ready, in emergent conditions, to improvise by her wits all lacking appliances, such as instruments, medicaments, or other needed aids; furthermore, to bathe, clothe, feed, and generally nurse an exceptionally suffering patient on call; to dominate by her will the patient's fears; to quell all attendant excitements; and to extend comfort and hope to the family of the sufferer.

These are some of the requisites demanded in the ideal physician on a sudden summons. Furthermore, when she is brought close to the ignorant, diseased, vulgar, or untidy, she must neither feel nor evince the slightest fear or repugnance, but she must be at once pitiful and firm, tolerant, tactful, and controlling, with wits alert for any and all professional inquiries or assertions, from the most ludicrously ignorant to the most profound and abstruse. She must have a memory that never lapses, but that will ever unfailingly carry the face, name, and medical history of every patient to the end of her days. Yes, naught but a genius could thus have all her powers in full readiness on a moment's call; and, yet, all this and more is expected and exacted of the ideal physician.

In person, she must be immaculate, while not fastidi-

ous; in spirit, daring, yet cautious; forceful, but gentle; earnest and dignified, sympathetic and patient; cheerful, affable, and brave; and, despite and even because of these almost superhumanly opposing qualities, the ideal physician must stolidly submit to be "called names," such as "how masculine," "how feminine"; and, although a veteran in her profession, she must, with gracious equanimity, frequently hear herself addressed or spoken of as "Miss" or "Mrs.," while her freshman brother, yet in college, is respectfully addressed as "doctor." And she must never be so indelicate as to rebuke another for this bit of injustice, not even her club sisters, who, by the way, I regret to say, are not always exempt from this offense. And her generous composure is further tested, on opening her daily mail, to find herself therein often tenderly addressed as "Dear Sir." At this point, we decline to embrace our brothers, and "she" is strongly and especially italicized. To proceed, she must be genial, buoyant, and responsive, however oppressed by professional care and anxieties or by the most suffocative confidences. She must be faithful to all the dark secrets and tragic histories of her patients, regardless of their desertion or their possible abuse of her in turn.

Again, the ideal physician must be boldly progressive and wisely conservative. She must love her profession and sacrifice herself ever to its noble service. She must work by day, study by night, with or without food or sleep; she must have the courage of her convictions, "neither buying nor selling," fearlessly and conscientiously serving this one, counseling that one, pitying here, rebuking there. She must, in truth, preach as well as practise, hoping little, fearing less; and she must also be humorously gifted, ready on the moment to give and take the salty of wit, though the next moment she gives judgment of death or stands beside the dying, for the power of innocent wit and judicious satire are important medical adjuncts. Thus, I repeat, this almost phenomenal combination of personal qualifications constitutes the ideal physician a genius indeed.

The ideal physician must also be Christian or philosopher, or, indeed, both, for upholding herself and the suffering one she serves. Mortal agony, mental hallucinations, heart distractions, and soul despair in a patient must often be controlled by citing the Christian promises, such as "rest for the weary," "take no thought for the morrow," "let not your heart be troubled," "peace be unto you," or by philosophical precept and admonition, such as "be sorry for nothing," "fear naught, fear not." Yes, the ideal physician must ever be the ready philosopher, as against all the odds and in the most desperate circumstances.

But, even more, the ideal physician, to kindly and nobly serve, must ever be a true lover of goodness. And the two proverbial pockets—the one, deep and capacious, for neglects and indignities; the other, the diminutive one, for honors and moneyed returns—are not sufficient to her needs. She must recognize no neglects, resent no criticisms, forgive all injuries. The ideal physician labors for results, not financial returns, and, aye, great the difference! So, deep in her heart is the third receptacle, where reposes the memory of every noble endeavor, of every expression of gratitude, of every sufferer helped, and the happy consciousness that a nobler, grander profession does not exist in which to labor with, and to serve, our suffering humanity. I therefore herewith render ardent homage to the medical profession and to its many ideal physicians.

Original Communications.

THE UNITED STATES ARMY RATION,
AND ITS ADAPTABILITY FOR USE IN TROPICAL CLIMATES.

By LOUIS L. SEAMAN, M. D.

(Concluded from page 379.)

In the command to which I had the honor of being attached as surgeon, the First United States Volunteer Engineers, the health of the troops was nearly perfect while in camp at Peekskill during June and July. Every recruit was vaccinated. Only one serious case of illness developed in the entire regiment, a pneumonia, the result of exposure in a cold storm at night, when the soldier was on sentry duty. During our encampment at Peekskill the State caterer supplied the troops with food fairly well adapted for a temperate climate, but unfortunately not such as should be selected for preparing them for a tropical residence. At my suggestion, and by order of General Griffin, the meat ration was reduced, and an equivalent of rice or meal substituted once daily, with an extra allowance of syrup, greatly to the benefit of the men, who previous to this time had suffered considerably from constipation. An encampment of seven weeks in Peekskill, where the regiment was mobilized and mustered, made it possible to eliminate every man who, after having been accepted, showed evidence of physical weakness, whether that weakness was induced by the change in the manner of living, or arose from defects that did not appear in the rigid physical examinations to which recruits were subjected.

Under orders from the secretary of war, we embarked from New York, August 6, 1898, on the transport *City of Chester* with a total of 1,114 officers and men, and arrived at Ponce, Puerto Rico, on the 16th of August with every man in fine physical condition. On November 17th we reembarked from Ponce, reaching New York on the 24th, and bringing with us a total of 904 officers and men. Of this number, 102 were convalescent or in the ship's hospital, while a large proportion of the remainder, if not invalided, were greatly reduced in weight and power of resistance. Of the remaining 210 who had gone with us, 12 were dead, 61 were left behind in the hospitals of the island, and 167 had been returned to the United States invalided, or as honorably discharged from the service. During the three months we were in Puerto Rico more than half the regiment had at some time been under treatment, a condition entirely unexpected, for the most stringent precautionary measures had been adopted to guard against disease. Camp sites were chosen with special regard to their sanitation, the highest and best drained localities having been selected, except during the first week, when we were temporarily camped at the Playa at Ponce, while engaged in unloading our

equipment and impedimenta. The latrines were placed at remote distances from the camp, were deep, were disinfected three times daily, and later were darkened by being inclosed with planks. Water for drinking purposes was procured from the purest available sources, and was boiled and filtered before being used. A thorough and rigid inspection of food and cooking utensils was constantly enforced, and camp discipline so excellently maintained that there was little drunkenness among the men. Personal cleanliness was also required, bathing twice a week being obligatory, and there were no forced marches, or undue exposure to the sun, engineering work and drills being suspended during the hottest portion of the day. We had medical supplies in abundance, and my assistants were able, efficient, and conscientious in the performance of their duty. Yet hundreds of cases of serious forms of gastro-intestinal catarrh and fever rapidly developed. With few exceptions the entire force suffered from some form of intestinal catarrh within a week after our arrival in Puerto Rico, due either to a change in drinking water, slight colds resulting from sleeping on the wet ground, eating fruits to which the men were unaccustomed, or the extreme relaxation of the system resulting from exposure to tropical heat, and the use of the rations provided. This catarrh continued most persistently and could scarcely be controlled by medication, for the diet, which should have been rice or some non-irritating food, proved a continual excitant to the disease. It consisted principally of fatty bacon, salt beef, canned tomatoes, frequently in a state of fermentation due to the intense tropical heat, canned beans, and hard-tack. The result was an aggravation of the disease, and the loss of weight to the soldier of from ten to fifteen pounds, in many instances much more. This loss represented a great latent power, a reserve force which stood between the soldier and disease, and which, when removed, left the system open to the invasion of malaria and typhoid fever and gastro-intestinal derangements of serious moment. His power of resistance was gone, and the virus of malaria and typhoid found in him a fruitful culture ground. Under such circumstances it was not surprising that the hospital was soon overcrowded, and the precautions taken against disease had little or no effect in warding it off. The most distressing feature was that the conditions were unavoidable, for the government had up to this time made no adequate provision for furnishing our men with other than the regular ration, and this was not only unsuitable, but was, during the climate, making serious inroads upon the health of the command.

The travel ration composed of 5 lbs. of hard bread commonly known as hard tack, 1 lb. of salt beef, canned, three quarters of a pound of dried beans, or canned tomatoes, a third of a pound of coffee, 1 1/2 lbs. of a pound, 1 lb. of sugar, 1 lb. of fat, and 1 lb. of

The troops who fought at Siboney and San Juan Hill ate this ration when they could get it, and this ration alone, except such additions as those Colonel Roosevelt added from his private purse, for nearly four weeks. We had it for nearly three weeks. It is intended as an emergency ration, to be used when troops are on the march or separated for a short period from their cooking facilities; but its effect on the American army, in the intense tropical heat of July and August, is recorded in the surgeon-general's office; or in the living pictures presented by the emaciated forms of convalescent troops sent home by the hospital transports; or is buried six feet or less deep in the soil of our new possessions.

The prevalent disease affecting our troops during the summer was primarily acute intestinal catarrh of a very debilitating type. At one time fully seventy-five per cent. of the soldiers were ill with diarrhoea, largely incapacitating them from the performance of their regular duties. Later, malarial fevers began to develop, of the intermittent and remittent types, and early in September typhoid fever manifested itself and continued to affect the troops with greater and greater severity until our departure for home in November. Nor has it yet stopped. In the moisture and intense tropical heat at Ponce the spores of microbes of typhoid were everywhere present, having been brought to the island by the troops from Tampa and Chickamanga. Probably many of them found entrance to the stomach or intestinal tracts of our men, and would have passed through harmlessly had the gastric juices and intestinal secretions been normal. The virulence of the germs became apparent only when the system was found to be in a debilitated condition, or the quality of the secretions was impaired. Under these circumstances rapid reproduction of the microbes occurred and typhoid was found in every camp on the island, having been disseminated through the agency of the myriads of flies with which the atmosphere swarmed. No case of typhoid or malaria had been known among the engineers from the time of their recruiting in June till nearly three weeks after their arrival in Puerto Rico. Indeed, through the entire summer the percentage of sickness with them was less by half than in many of the other commands on the island, regular or volunteer.

For a week after landing, our regiment, as before stated, was subsisted on the travel ration. Regular field rations were not issued until August 23d. By that time the beef brought from the United States had become so tainted that it had been condemned by a board of survey and buried. Fresh beef was contracted for, but, owing to climatic conditions and lack of facilities for keeping, it was necessary to consume it the same day it was killed, notwithstanding its flatness and unpalatable taste. The greatest difficulty was also experienced in obtaining rice and fresh vegetables from the commissary department. Those brought by the regiment rotted on

the ship before they could be landed, and those issued by the commissary were so decayed as to be, for the most part, unfit for use. I believe if we had had a cargo of rice and potatoes in Ponce in August the sickness of the army there would never have reached half its proportions. This condition of affairs continued until the 20th of September, when new supplies arrived and we were in a measure relieved. Whenever fresh meat was issued by the commissary the soldiers were compelled to accept it, often against their protests, but it was a "perishable article," and the United States army regulations do not permit any commutation for perishable articles. So there was no changing it for other food. The effect of such fresh meat upon troops is notoriously injurious in tropical countries under certain conditions, often producing diarrhoeas of an almost epidemic character.

My experience while in charge of the convalescent camp of the Nineteenth United States Infantry, where there were many hundred troops at various times from the Second and Third Wisconsin Volunteers, the Sixth Illinois, Sixth Massachusetts, Sixteenth Pennsylvania, and other regiments, and the overcrowded hospitals at Coamo and Ponce; and the opportunities I had for observation while supervising the loading of transports with convalescent soldiers, convince me that had the ration been promptly changed when its evil effects were first observed, transport after transport would not have been sent home loaded with emaciated, broken-down soldiers. As I have stated in the *Century Magazine* of this month, had the ration received the attention it called for, there would have been comparatively little sickness, and hospitals would have played a minor part in the tragedy of the war. The hue and cry raised all over the country that medical supplies were insufficient was based upon false rumor. We had abundance—far more than we could use. It was not drugs that the soldiers needed, but proper prophylactic treatment—diet, well-regulated diet—and that could not be obtained during the month of August and the greater part of September, except through private sources and the Red Cross and relief societies. The fresh milk that was so essential for our hospital patients during these two months was furnished by two charitable individuals, while the food supplied by the Red Cross Society proved a veritable godsend.

A recent order of the surgeon-general has happily allowed the sick in field and regimental hospitals sixty cents a day as commutation for ration, the same privilege as that enjoyed by division and general hospitals. But this allowance should be still further extended so as to include, at the discretion of the surgeon in charge, those men reported as "sick in quarters." These men are frequently in as great need of a change in ration as those actually in hospital, and in many instances it would save them from eventually becoming hospital patients.

As before stated, for a temperate or northern latitude, the army ration is fairly satisfactory; but in Puerto Rico and Cuba, where the temperature ranges high, and where the conditions predispose to bowel complaints among unseasoned troops, it is totally unfit. No better evidence of this can be had than in the hospital records, where it is shown that the best results in treatment were obtained, not by the use of drugs, but by placing patients exclusively on a milk diet. In the hospital of the quartermaster's department, under the care of Surgeon Moret, a native Puerto Rican, where I was frequently called in consultation, there were a hundred and thirty serious cases of illness, all of whom were put on a diet of pure milk. In every case but two, and these were hopeless on admission, there was rapid recovery, a fact which tends to show that had the army been provided with a ration in which the carbohydrates were given a greater and the nitrogenous-elements were given a lesser part, there would have been far less recorded sickness and mortality. Indeed, I am fully convinced that had our army been properly prepared for tropical service by being fed on a judicious diet prior to the invasion of Cuba and Puerto Rico, and during its stay in the tropics, sickness and mortality would have attained very different proportions.

The pathological features of the cases on which we were fortunate enough to hold autopsies, whether the causes of death had been pronounced intestinal catarrh, hepatitis, duodenitis, typhlitis, enteritis, enteric or typhoid fever, colitis, dysentery, or diarrhea associated with malaria, presented many similar characteristics. The liver was almost invariably congested. The mucous membrane of the intestine was pale and covered with a thick, tenacious, adherent mucus; the mucosa was hypertrophied, often deeply congested, and ulcerated; in two instances these ulcerations almost encircled the entire tube. The toughness of the opaque secretions obliterated the intestinal glands, causing atrophy, and thus interfering with absorption and metabolism. The solitary follicles stood out with prominence, and the patches of Peyer were distinct, often with minute ulcerations on the surfaces, notwithstanding many of the cases in which they were found presented no characteristic typhoidal temperatures, and during life failed to respond to the Widal reaction.

Why is it that a simple intestinal catarrh, a diarrhea with malaria, a mild duodenitis or enteritis is aggravated when salt meat, beans, fat pork, fermenting tomatoes, etc., are taken into the intestines? Because they act as irritants, exciting instead of allaying inflammation, thus engendering a comparatively trifling disorder one of serious proportions. One was almost as much puzzled to know how to sign a certificate of death after an autopsy as before, for the diseases seemed to be blended, the areas of congestion or inflammation being only slightly interrupted, or of a general character. The diagnostic features were so tangled and massed as to

make differentiation extremely difficult, and to almost lead one to the conclusion that the enteric diseases prevailing last summer in Puerto Rico and Cuba were of a new form or development. They were the result of a tin-canned-salt-junketed-fermenting-tomato-salt-pork diet, intensifying a simple catarrh; and resulted in sending so many of the rank and file of our men to the hospitals of the North, or elsewhere, in the pitiable conditions with which you are already too familiar.

The simple catarrhal affections of the stomach and upper intestinal tract, not resolving rapidly, will lead, under an unsuitable dietary, to congestion of the liver, with all the dangers attached to such a state, in a climate where the natural antiseptics of the intestine is of such paramount importance. The reduction in quantity of bile will lead to auto-intoxication and extension of the processes of inflammation, until the entire intestinal tube may be involved, and jaundice, duodenitis, enteritis, and colitis are developed—conditions which are an open door for all micro-organisms that can find entrance.

A much greater flexibility to the ration will be absolutely essential if Congress adopts the practical lead of England in garrisoning our tropical possessions with native soldiers. England's success in this line has been so great that the next addition to her colonial army will be known as "The Wei-ba-Wei Battalion," made up of Chinese. In Africa she employs the African; in India, the native regiments, especially the Sikhs, who are among her most formidable fighting machines, and on whom in her border wars she places her chief reliance. I have seen these magnificent specimens of manhood, often six feet six to six feet eight inches in height, serving as her guardians of the peace, in the various coast cities of the Orient, and few soldiers present a finer appearance. In South Africa she has a regiment of Zulus; in Jamaica, natives are employed. Indeed, wherever the flag of England floats there you will find garrisons selected from her colonists, and her own regular army is rarely called upon for service except in sudden emergencies or the event of war. Her example must soon be followed by us in our tropical possessions unless we wish to establish a mill for the physical degeneration of the flower of our army, and a further apology for the extension of our pension rolls.

Since the ration, then, has proved such an improper diet in the tropics, the question naturally presents itself, What is a *suitable* ration? Before proceeding to make suggestions in answer to this question, it will be well to point out more specifically the defects of the present ration, which consists, as will be seen from the chart, principally of salted and fresh meat, flour or flour, canned beans and tomatoes, and a small quantity of cereals, with little provision for the fruits and vegetables. The experience of the British in Barbadoes and the West Indies has shown that the salt ration is the greatest predisposing cause of bowel complaints. As stated by Dunn

can: "In the first Burmese war, for six and a half months the troops had salt rations shortly after its commencement, and forty-eight per cent. of them perished within ten months, principally of scorbutic dysentery; while in the regiment of Cameronians, seven hundred out of nine hundred were rendered unfit for duty from the same cause within a period of two months. In both instances these diseases were induced by an almost exclusively salted diet, which not only irritated the intestines, but did not furnish sufficient nutriment. It was observed in the West Indies, in the Windward and Leeward command, that after an issue of salt rations five days in the week, the mortality among the officers was two to four per cent., while that among the men was twenty per cent. When the issue of salt ration was reduced to two days a week the mortality among the men was soon the same as that of the officers."

Next to that of salt rations, an excess of fresh meats is a cause of bowel derangements. This was strikingly shown by Lamaran, in the French campaign in Algeria, when the men ate excessively of captured mutton, and rapidly succumbed to bowel disorder. As previously stated in my own experience in Puerto Rico, it was observed that when men already sick with diarrhea from eating the regular meat ration were placed on a diet of milk, they in most instances rapidly recovered with little or no medication.

Another article largely issued in the late war, and which was found to be very objectionable in the tropics, was the tinned and also the dried bean. It was observed that every issue of beans after the men had been a short time in Puerto Rico was followed by an increase of diarrhoea. The beans often fermented in the stomach or intestines, and were frequently passed from the bowels unchanged. This result occurred with the canned baked beans, which were of excellent quality, as well as with the cooked dried beans. No trouble was found to follow with the eating of the red or black bean, the *frijol* of the country.

Owing to its heat-producing qualities and its irritant effect upon the intestine, the *salt-pork ration* should be greatly reduced in quantity, and should be issued but once in a week at most. This ration was almost wholly rejected by the men of my regiment in Puerto Rico, and was useful principally as a means of exchange for fresh vegetables.

The canned tomatoes furnished to the troops during their service in Cuba and Puerto Rico, and of which there is a sufficient supply piled up in the Government storehouses of the island to last several years, do not take the place of the fresh product, which in nearly every place is plentiful, and so cheap that six or eight can be bought for a centavo (half a cent). The tinned goods are frequently found in a state of fermentation and should never be issued when the fresh article can be obtained.

In making suggestions for the selection of a proper

ration for troops in hot climates, it is not proposed to go extensively into the question of the relative amounts of carbon, nitrogen, and salts required to yield the necessary foot tons of energy to enable the soldier to perform his daily task. These are already sufficiently well known, and the present ration of the United States army, although susceptible of improvement, answers well its purpose in temperate or cold climates. My object is to select a ration which shall furnish the necessary energy, and which at the same time can be digested and assimilated in a tropical climate without damage to the digestive apparatus. It is well known, and but little actual observation is needed to convince the most skeptical, that the conditions of heat, moisture, and malaria inevitable to service in the tropics, especially in the summer months, predispose powerfully to both catarrhal and inflammatory diseases of the liver and intestinal tract. In a large proportion of the men these diseases, as before stated, are manifested soon after their arrival, especially in the summer, no matter what sanitary precautions are taken. If, then, the soldier is fed upon an unsuitable diet, it takes but a short time for the intestine to reach the condition described under the head of pathology, and he is either soon dead or invalided home. If, on the other hand, a suitable, unirritating diet is provided, the simple catarrh will soon disappear, and in most cases sanitary precautions, supplemented by an appropriate ration, will prevent its reappearance.

In view of these facts, the first requisite of the ration is that it shall be *non-irritating and easily digested*. It must also be easy of transportation, proof against climatic changes, and susceptible at all times of the greatest flexibility. None of these requirements does the present ration meet as it should. It has been abundantly shown that with the great majority of the men it can not be properly digested. It is none too easy of transportation, as was evidenced by the meagre supply of food some of the troops had to subsist on during the summer campaign. It is not wholly stable in all climates, as we have already observed, and it is not sufficiently flexible for use in all climates. In fact, it is scarcely flexible at all, except in garrisons, where to a limited degree certain of the articles of its constituents may be commuted for other supplies in kind, or for their money value. In the latter instance the money goes into what is known as the company fund, whence it is drawn for the purpose of such variations in the diet as the company's commander may see fit to provide for his men. Post gardens sometimes add to the bill of fare, and, by lessening the demand for full commissary rations, increase still further the company fund; but the flexibility of the ration should not be made to depend upon post gardens or company funds—it should be a characteristic of the ration itself, and no new formula of diet should be enacted by Congress in which this is not embodied.

In the changes I have to suggest for feeding the army under tropical or subtropical conditions, it is not proposed to recommend a complete ration with the definite quantities of its various items, but rather to point out briefly such changes as experience has shown to be necessary to fit the ration for the use intended, and I would say that these imposed changes have met the approval of many officers with whom I have discussed them. These recommendations are as follows: The beef component and the salt pork should be reduced *one half*, farinaceous food being substituted therefor. Salted rations should be issued but once, or at most twice, during the week. Fresh meats should be provided from animals slaughtered at the point where issued. At points where native cattle in good condition can not be procured, cattle from Texas can be as easily transported by the government of the United States as the merchants who now supply the Cuban markets from Texas and Mexico. Of the cereals, one of the best is hominy. The hulls of the maize being removed in the course of its manufacture, this source of irritation is avoided, while the grains, when softened by a thorough cooking, are nutritious, easily digested, and relished by the men. Equally valuable is the ration of rice now issued, and which should be quadrupled in quantity.

The white bean of this country should *not* be issued for use in the tropics for the reasons previously stated. In its place should be used the black or red native bean (*frijol*), which, while resembling the common bean in shape, is very different in its properties. The hull is much thinner, and when thoroughly cooked does not irritate, while the pulp is drier, breaks up readily with cooking, and is easily acted on by the digestive fluids, and does not produce irritation.

This bean, together with the tortilla, practically made from hominy, forms almost the entire diet of the Mexican army, and there are few if any soldiers who can endure greater fatigue, or make longer marches, or among whom is less sickness from dietary causes.

In addition to the above, dried fruits, especially apples and prunes, should be added to the ration. Their effect when used in Puerto Rico was invariably observed to be beneficial.

Another and very marked factor in the development of the intestinal troubles which so seriously affected the army in Cuba and Puerto Rico was the manner in which the ration was usually cooked. The old saying that the Lord made the food, but the devil made the cooks, was never better illustrated than during my service in Puerto Rico, where the majority of the men detailed as camp cooks were not possessed of even the most elementary knowledge of the subject. The execution of proper cooking, important everywhere, is doubly so in the tropics, where the digestive organs require every possible aid to enable them to efficiently perform their functions. If the cereals are not thoroughly cooked, the hull is not sufficiently softened and broken

up, and acts as an irritant; while the other portions are difficult of digestion in proportion as they are underdone. The fibres of meat when half burned up in hot fat, as is frequently done, are not only deficient in nutriment, but are a severe intestinal irritant and almost invariably produce diarrhoea.

The remedy for this condition is obviously the establishment of schools for the training of camp cooks, and there is no one measure that will do more to maintain the efficiency of the army in the tropics than this.

In this connection it may be added that nothing is more needed in the curriculum of the United States Military Academy than a course of training in practical hygiene and camp cooking. No officer is fit to command a company who is not scientifically familiar with these most important subjects.

If the health of an army is to be maintained the diet must be varied. To insure this, as well as a plentiful supply of fresh vegetables, permission should be given to the company commanders to draw upon the commissary for such elements as the commissary stock now supplies; or, at their discretion, and with the approval of their regimental surgeon, *cash* commutation for the entire ration, the same to be used for the purchase of vegetables and such other necessities as may be best adapted to the environment of the troops. In other words, I would make it possible to requisition the invaded country for the food required to feed the invading troops as well as for those in garrison.

Could we have had such a ration in Puerto Rico and Cuba as I have described, or if but a small percentage of the vast outlay afterward expended in the cure and treatment of the sick had been employed in procuring proper food before disease had developed, an enormous saving would have resulted, and future pension rolls would have been kept within narrower bounds.

Having already compared our ration with that of the British in India, and having shown at length its utter unsuitability for use in the tropics, let me, in closing, ask you for a moment to consider the ratio it bears to that issued to the soldiers of other nations living in temperate climates, where a larger proportion of meats—nitrogenous and fatty elements—are required than in the tropics. The American soldier gets 22 ounces of salt meat or 20 ounces of fresh meat and 58 ounces of bread and vegetables daily. The German soldier and, man for man, he is the best trained fighting machine in the world of to-day, has a daily ration of fresh meat, 5.50 ounces, or 5½ lb., 4.11 ounces, and vegetables, including bread and potatoes, 7.04. It will be observed that the German allowance is less than a quarter that of the American soldier in the tropics, while the quantity of vegetables is double.

all below the 98.4° F. line; the "slight fever," 98.4°-101° F.; the "distinct fever," 101°-104° F.; and the "marked fever," 104°-107° F. For everyday practice the zone above 107° F. may be unnamed.

This simple and well-known device has proved itself so practical and valuable after adoption in the New York Hospital at the writer's suggestion that perhaps some others may find it worthy of trial.

7 WEST FIFTEENTH STREET.

ON A POLYMORPHOUS CEREBRAL TUMOR

(ALVEOLAR GLIOMA*)

CONTAINING TUBERCLES AND TUBERCLE BACILLI*

By CLARIBEL CONE, M. D.

PROFESSOR OF PATHOLOGY, WOMAN'S MEDICAL COLLEGE, BALTIMORE.

[From the Pathological Laboratory of the Johns Hopkins University and Hospital.]

(Concluded from page 366.)

Conclusions.—Thus it will be seen that the tumor under discussion presents the appearance of several histological types—carcinoma, sarcoma, and glioma. The carcinomalike areas are simple alveolar and tubular. The sarcomalike areas show the structure of simple sarcoma and of endothelioma. The areas which resemble glioma show a diffuse intermingling of tumor cells with highly refractile fibres. Moreover, transitions between the different histological types are found, showing that all must be regarded as different modifications of the same kind of growth.

If now we return for a moment to a consideration of the various forms of neoplasms which are known to develop from neuroglia we shall find that only those tumors have been regarded as carcinomata which have taken origin in the adult ependymal cell. If what has gone before is borne out, it is probable that the tumor under discussion is not a carcinoma in the true sense of the term, but only another form of glioma; and since its apparent tendency is to present itself in alveolar form, it might well be designated "alveolar glioma." This name has the twofold advantage of indicating the nature and origin of the neoplasm, and at the same time distinguishing it sharply from secondary, metastatic forms of cancer. According to this conception the tumor would correspond with such a one as was proposed by Dr. Flexner¹ to arise from the adult ependymal cells.

Applying the scheme for the diagnosis of tumors suggested at the beginning of this paper we find that in this case the initial stage of tumor formation can not be followed because the growth had progressed too far. The peripheral transition from atypical to normal tissue can not be traced because of encapsulation of the

growth, and, unfortunately, the neighboring structures were not preserved. The tumor, furthermore, occurs in the brain, from which organ epithelium, in the ordinary sense, is normally absent; and it occurs in a part of the brain which has no connection with even the normal ependymal cells. This would not, however, exclude secondary growths, but such have already been excluded in this case by the findings at autopsy. The possibility of embryonic misplacement still remains.

There are few data, therefore, other than histological, upon which dependence can be placed in forming a definite diagnosis, and the latter are complex and confusing. Taking the histological type as the basis, together with what additional factors—clinical and other—may be found both for and against each growth, an attempt will be made at differentiation.

In favor of *carcinoma* are: (1) The alveolar and tubular structure of the tumor; (2) the epithelial-like type of cell, cylindrical, cuboidal, and polyedral; (3) the hyperchromatism of the nuclei; and (4) the atypical nuclear figures (Hansemann).

Against *carcinoma* are: (1) The circumscribed character of the growth; (2) its apparent encapsulation; (3) certain diffuse sarcomalike areas found in portions of the tumor; and (4) the absence of tumor formation elsewhere in the body, which can be regarded either as primary or secondary to this growth.

Added to these may be mentioned (5) the infrequency with which carcinoma of the brain, either primary or secondary, has been found.

The complete separation of the tumor from the ventricles may be said to militate against the carcinoma theory, but not entirely to exclude it, since here, as in the epithelial inclusions described by Stroebe* and others, a separation of the tumor germs may have occurred in the early embryo.

In favor of *alveolar glioma*, as of *carcinoma*, are: (1) The presence of alveoli and tubules, and (2) the epithelial-like character of the cells, which may be said to resemble choroidoid epithelium, as this is seen in preparations preserved in alcohol or allied fluids.

But an additional factor for alveolar glioma may be found in (3) the peculiar highly refractile neuroglialike fibrils scattered in places among the cells.

Opposing the theory of alveolar glioma are: (1) The absence of the typical ependymal cell characterized by its long filamentous process, and (2) the circumscribed character of the present growth, which is unlike the infiltrating nature of glioma. It is possible, however, that with more complex organization the glioma may take on new biological characteristics. (3) As a third opposing factor to alveolar glioma may be mentioned the complete separation of the tumor from the ventricle. But this, as in the case of carcinoma, would not exclude such gliomata as originate from embryonic inclusions.

* Read before the twenty-third annual meeting of the American Association of the Woman's Medical College of Pennsylvania, held May 19 and 20, 1898.

† Flexner. *Op. cit.*

* Stroebe. *Op. cit.*

In favor of *endothelioma* are: (1) The circumscribed character of the growth; (2) the absence of tumor formation in other organs of the body; (3) the arrangement about the blood-vessels in cellular cords which are themselves made up of groupings of tubules; and (4) the occasional transition from the more complex types to diffuse sarcomalike tissue. Indeed, this resolving of a complex structure into its simple constituents is more characteristic of *endothelioma* than of any other growth, and does much to render probable an ultimate diagnosis of *endothelioma*. And the arrangement in cellular cords about the blood-vessels is typically characteristic of that form of *endothelioma* known as perithelial angiosarcoma.

(5) An additional point in favor of *endothelioma* is the fact that there are no positive data to oppose such a diagnosis. For every one of the types of tumor represented in this specimen may be interpreted as a different modification of the complex endothelial growth, while the less complex tumors—carcinoma and alveolar glioma—would be less apt to assume the perivascular form.

As to histogenesis, we have seen that in this special case the initial stage of tumor formation can not be followed. Nor can a transition be shown in the periphery of the growth from atypical to normal tissue. But a consideration of the usual modes of genesis for the several types of neoplasm here represented may aid in the elucidation of this growth.

Carcinoma, as we have seen, is rare in the brain. Here, as elsewhere in the body, it is supposed to take origin from epithelial elements, whether adult or embryonic, and these elements are derived, as we know, from the ectoderm. The epithelia of the brain are the ependymal lining of the ventricles and the epithelium covering the chorioid plexuses. The so-called primary carcinoma of the brain would thus be found as a growth continuous with one or the other of these epithelial structures. Or, if due to an embryonic misplacement, the tumor might possibly be separated from the epithelium, lying deep within the medullary substance as a heteroplastic growth.

Glioma has been described as the most frequent variety of tumor found in the brain. Like carcinoma, it takes rise from cells originating in the ectodermal structures which for glioma are the several neuroglia elements.

It will thus be seen that the ependyma has been regarded as the starting point for two dissimilar neoplasms, the ordinary glioma and the carcinoma. It will therefore be of interest to inquire whether a distinction actually can be made between these two types of tumor.

That tumor having the morphological structure of carcinoma can originate in the ependyma is proved by the case of a so-called "primary carcinoma of the fourth ventricle," reported by von Wunneheim, in which he

has shown a direct connection between the ependymal epithelium and that covering the chorioid plexus on the one hand, and the epithelium of the tumor on the other. He believes that the place of transition between the ependymal epithelium and the plexus epithelium was the starting point of the tumor.

That glioma also springs from ependyma is shown by the presence of epithelial-lined cavities within certain gliomata, such as have been described by Stroebe, Buchholz, and Henneberg for the brain, and similar epithelial misplacements in the numerous cases of syringomyelia with which the literature abounds.

That ordinary carcinoma and certain forms of glioma have hitherto been confounded is now clear.

Perhaps a solution to the difficulty may be found in the theory that while both carcinoma and glioma are derived from the same blastodermic layer in the embryo, the ectoderm, they originate from this structure at different periods of its development. The carcinoma may therefore correspond with the ectodermal cell of an earlier embryonic period, while glioma would be derived from the ectodermal cell after it has become differentiated into the spongioblast of the primitive neural canal.

According to this theory the term carcinoma may be applied only to those neoplasms whose germs have originated as ectodermal inclusions in the early embryo; while such growths as originate at a later period, from the spongioblast in the embryo, or from the developed ependymal cell of the ventricles or the chorioid plexuses in the adult, must be regarded as gliomata.

Herein may perhaps lie an explanation of the infrequency with which carcinoma occurs in the brain, and the relatively greater frequency of glioma.

And, indeed, in the absence of evidence to the contrary, there is no good reason to believe that those neoplasms, already described in the literature as cerebral carcinoma, may not have been glioma of organoid type—that is, tumors which have the same ultimate histogenesis as carcinoma, but which correspond with the cell of a later developmental stage. Such a tumor would complete the scheme of classification for glioma suggested by Dr. Flexner, in which certain well-known types are referred to certain forms or stages of development of neuroglia. And as there are types whose cells correspond with the astroblast, others whose cells are like the astrocytes, and still others composed of the embryonic ependymal cell, so the tumor in question would correspond with the fully developed or adult ependymal cell. Such an organoid tumor would perhaps represent a type between carcinoma and the simple glioma.

What then is the probable nature of the tumor described? This question is not easy to answer, and different observers would doubtless be led to conclusions somewhat contrary. There would seem, however, to be more than a possibility that the tumor, primary in the

cerebral substance, sprang from adult ependymal epithelium which was included within the depth of the cerebral substance, and that the growth was entirely separated from the ventricles at the time of the autopsy.

As to the relation of the tuberculosis to the neoplasm, the former everywhere pervades the tumor as diffuse tubercle tissue or as discrete microscopical nodules. The tubercle tissue is more marked in certain areas than in others, and is most developed in the stroma and the capsule. Tubercle bacilli and typical giant cells are present.

The acute inflammatory exudate must likewise be regarded as a tuberculous product, since no other causative agent could be found.

The tumor is often broken up by the diffuse infiltration of tubercle cells and polymorphonuclear leucocytes. The tuberculosis must therefore be regarded as secondary to the tumor formation both because of the diffuse infiltrating character of the tubercle tissue and because of its limited extent.

The primary focus of the tuberculous infection is more difficult to determine. The tuberculous lesion of the brain itself was demonstrated only upon microscopical examination, so it can not be said that the primary focus did not exist elsewhere in the body. But in the absence of such evidence the brain tumor must be regarded as a *locus minoris resistentiæ* which favored the development of tubercle.

There is but little literature upon this subject. One case has been brought to my notice in which tuberculosis complicated a case of glioma. Perhaps in the future it will be shown for brain tumors, as has already been shown for neoplasms elsewhere in the body, that this association is not so uncommon.

In conclusion, I wish to thank Dr. Flexner for many valuable suggestions during the course of this work, and Mr. Brödel and Mr. Becker for kind criticism of the drawings.

A FURTHER REPORT ON THE USE OF "ANTIPTHTHISIC SERUM, T. R." (FISCHL) IN TUBERCULOSIS.

By A. MANSFIELD HOLMES, A. M., M. D.,
DENVER, COLO.

ALTHOUGH serum therapy in tuberculosis has encountered much opposition, still a good deal of evidence in its favor has accumulated, the accuracy of which can not be questioned. And yet, even with this rapidly accumulating evidence before us, many physicians who have acquired not a little reputation in the therapy of tuberculosis emphatically condemn the treatment without having given it a personal test, or, what is worse, an honest test. Every one is, of course, entitled to a point of view, but it seems but fair in this discussion—one so pregnant with interest both to the laity and mem-

bers of our profession—that opinions should be expressed as such, and not as facts.

In the study of the therapy of tuberculosis we are, as in every other department of human endeavor, searching for truth, and the facts we desire are obtained only after careful clinical observations, carried out in accordance with recognized scientific principles. Dogmatic statements, or judgments formed prematurely, and from insufficient data, are unsafe and unworthy the argument; such it is my purpose to avoid. Obtaining what I considered good results early in my experience with the serum, I was encouraged to test it further.

My first report, published in the *Journal of the American Medical Association*, February 5, 1898, gave the result of my first three months' experience, ending December 1, 1897. I now wish to report my observations to January 1, 1899, covering a period of sixteen months.

Great latitude has been observed in classifying the types and stages of tuberculosis. I consider a definite classification important in order to avoid a misunderstanding as to the nature of the cases reported, and also to avoid unnecessary repetition of the physical signs and symptoms which otherwise would render the report unnecessarily long. Many data have been noted and could have been incorporated, but space would not permit. Hence, I have endeavored to give only such facts as will enable the reader to make his own deductions.

For convenience I have adopted the following classification: First, "pretuberculous" and early-stage cases *without* bacilli. Second, early-stage cases *with* bacilli. Third, chronic cases of long standing. Fourth, acute cases with "mixed infection."

In this connection I wish to state that each patient has been under my personal supervision. The blood and sputum have been carefully studied; the progress of each patient noted; the observed phenomena recorded, classified, and compared, and an attempt made to interpret them. The results I wish the reader to judge for himself. When possible, the tuberculin test has been applied when there was a question as to diagnosis, and at the close of treatment.

It is frequently the case that patients improve as a result of enjoying the advantages of a well conducted sanatorium. This factor should always be considered in forming final opinions of any treatment. The cases included in the report were those of my private patients. Hence, improvement emanating from an exceptionally ideal hygienic environment may be a confounding factor in this study.

The report has been prepared with a view of giving special attention to the following points: First, duration of the disease at the beginning of the serum treatment. Second, length of time spent in the sanatorium previous to beginning the serum treatment. Third, condition at beginning of treatment. Fourth, length

of time under treatment. Fifth, condition at close of treatment. Sixth, time since close of treatment. Seventh, present condition.

CLASS I. "*Pretuberculous*" and *Early-Stage Cases without Bacilli*.

The exact beginning of any case of tuberculosis is by no means easy of determination. A few observers, however, are beginning to recognize the possibility of making a diagnosis before the disease advances to the stage of expectoration. Hence, I deem it unnecessary to apologize for including such a class in my report, since it must be acknowledged that every well-developed case of tuberculosis passed through a period (however remote) in which bacilli could not be discovered. This class will therefore include cases with a strong tuberculous family history, each patient having experienced a shorter or longer period of impaired health, during which many of the important symptoms of the incipient stage have already developed, but no bacilli were found.

CASE I.—Mrs. R., aged twenty-five years; nativity, Kansas.

Family History.—Tuberculous on father's side.

Personal History.—Resident of Colorado three years. Had lost weight and strength during several months without any apparent cause. A dry cough developed, with intermittent pains in right lung. Slight hemorrhage one month before coming under observation. Sputum was also tinged with blood.

Examination, November 20, 1897.—Patient confined to room. Small area of dullness in upper lobe of right lung. Fine râles on forced inspiration. Temperature slightly elevated; pulse rapid and feeble; pain in lungs; troublesome cough; small amount of sputum, and no bacilli found.

Serum treatment instituted November 23, 1897, and continued three months. Weight at beginning of treatment, eighty-five pounds. During first month gained twelve pounds; coughed less; pain in lungs ceased; gained strength. During second and third months improvement continued; weight, one hundred pounds—a gain of fifteen pounds. General health continued to improve during several months after close of treatment, a period of nine months; no relapse.

CASE II.—Mr. B., aged sixty; nativity, Maine.

Family History.—Tuberculous. His wife also had chronic tuberculosis during several years, and died about one year previous to the first appearance of his disease.

Personal History.—Resident of Colorado nineteen years. Disease developed slowly; periodic pains in right lung experienced during a period of two or three years; no cough; marked daily fluctuation in temperature; temperature frequently subnormal. Symptoms began to increase in April, 1896. Obligated to give up work in June, 1896.

Examination, June 5, 1896.—Marked infiltration and consolidation of right lung; fine râles along lower and external border; Left lung normal. Cough troublesome; expectoration scant; no bacilli found. Temperature, 101° F.; pulse, 88.

Patient gave up work during three months; health

improved, but infiltration remained stationary. During the spring of 1897 administered serum from horse prepared by immunizing with old tuberculin; continued the use of this serum two months; considerable gain resulted; patient stronger, but consolidation continued. Improvement maintained until June, 1898, when former symptoms recurred.

Began the use of "antiphthitic serum, T. R." January 8, 1898, and continued one month. At close of treatment, dullness over right lung had greatly diminished; lung expansion increased three quarters of an inch; no râles; condition better than at any time since beginning of disease. One month later gave three tuberculin tests, one, five, and ten milligrammes, respectively; no reaction. Ten months have elapsed since close of treatment. Excellent health to date, with no tendency to relapse.

CASE III.—Mr. H., aged twenty-two years; nativity, New York.

Family History.—Tuberculous on mother's side.

Personal History.—College student. Disease developed during spring of 1897. Began with severe cold, followed by pain in lungs, cough, and expectoration; loss of weight and strength. Came to Colorado in June, 1897, on advice of his physician. Previous to coming under observation had resided in Colorado three months, with but little improvement.

Examination, August 3, 1897.—Very slight evidence of lung lesion; small area of dullness over upper lobe of left lung, with localized infiltration; a few fine râles; cough and expectoration, but no bacilli were found.

Began serum September 4, 1897; continued its use one month; patient gained three pounds; cough and expectoration ceased; no pain in lung. I advised a longer use of serum, but patient was obliged to leave Denver, but remained in Colorado. Fourteen months have elapsed since close of treatment; frequent examinations have been made and no evidence of disease found. Has been in college or otherwise employed; visited his home in New York city during the past summer; health better to-day than ever before. At present a resident of Colorado.

CASE IV.—Miss S., aged thirty-four years; nativity, New York.

Family History.—Tuberculous on mother's side.

Personal History.—Early symptoms of tuberculosis developed during spring of 1892. Came to Colorado in 1893 on advice of her physician. Experienced some gain from rest and climate, but this was soon lost and patient began rapidly to decline.

Examination, September 1, 1897.—Small area of consolidation in upper lobe of right lung; no râles; troublesome cough and sputum, but no bacilli were found. Afternoon temperature about one degree above normal; pulse between 90 and 100. Face and back covered with acne vulgaris, which had existed since puberty.

Began serum September 15, 1897; continued two months. At close of treatment cough and expectoration had ceased; no pain in lungs; temperature and pulse normal; acne completely disappeared and has not returned. Health remained good for nine months after close of treatment, when former symptoms showed evidence of returning; loss of weight and strength; troublesome cough; small amount of expectoration; pain in right lung. This condition continued several weeks before next consultation.

Examination, November 15, 1898.—Râles through-

out greater portion of right lung; marked infiltration of lower lobe; moderate fever and rapid pulse; patient very weak; cough troublesome; expectoration scant, but no bacilli found. I advised beginning serum again. Patient delayed for one month, hoping symptoms would abate. At close of a month patient was worse and came for treatment. Commenced serum again December 16, 1898; improvement began almost immediately; is now making rapid progress; all symptoms abating; treatment continued.

CASE V.—Miss J., aged twenty-two years; nativity, New York.

Family History.—Tuberculous on mother's side.

Personal History.—Present trouble began during December, 1896. Pains in left lung; cough; loss in weight and strength. Came to Colorado in August, 1897, on advice of her physician; remained in Colorado four months, with little improvement.

Examination.—Nothing abnormal detected in either lung, but patient complained of pain in lungs and suffered from irritable cough; very weak; appetite poor; temperature, 99° F.; pulse, 104.

Failing to find a sufficient cause for her condition, I advised serum, suspecting incipient tuberculosis. I regret that a tuberculin test was not made at the beginning of treatment. Began serum December 19, 1897; continued two months with marked improvement in every respect. Temperature and pulse returned to normal; cough ceased; strength increased. At close of treatment gave tuberculin test with no reaction. Patient secured employment soon after close of treatment; health has continued good. Normal weight of patient, one hundred and thirty-two pounds; on beginning treatment, one hundred and twenty-one pounds; at close of treatment, one hundred and twenty-eight pounds; present weight, one hundred and thirty-two pounds and a half.

CASE VI.—Miss R., aged nineteen years; nativity, Massachusetts.

Family History.—Pulmonary tuberculosis on mother's side. Intestinal tuberculosis on father's side.

Personal History.—Symptoms of intestinal tuberculosis appeared in 1895, which would not yield to treatment. Followed a rigid diet, with poor results. Came to Colorado in 1897; no improvement.

Examination, October 1, 1897.—Moderate tympanites; abdominal tenderness; chronic diarrhea; all foods disagreed; lungs normal; no cough or expectoration. Patient also suffered from an aggravated form of acne vulgaris, covering face and back, which had existed several years.

Commenced serum October 13, 1897; continued three months. General condition improved as treatment progressed; appetite increased; intestinal symptoms abated and finally disappeared; gained in strength; gained five pounds in weight; acne completely disappeared and has not returned. Ten months have elapsed since close of treatment and there has been no return of disease.

CASE VII.—Mr. S., aged twenty-nine years; nativity, Missouri.

Family History.—Tuberculous.

Personal History.—Artist. Contracted a severe cold in 1897, which failed to yield to treatment. Feared tuberculosis, and came to Colorado December 1, 1897.

Examination.—No distinct lung lesion found; bronchial breathing and slight increase in the vesicular mur-

mur; no râles; pain in lungs; dry cough; expectoration moderate, but no bacilli were found.

Began serum January 8, 1898; continued one month with improvement. At close of treatment gave the tuberculin test, with no reaction. Continued to improve after stopping treatment. Ten months have elapsed with no relapse.

CASE VIII.—Mr. R., aged thirty-two years; nativity, Illinois.

Family History.—Tuberculous. Father and brother died of tuberculosis.

Personal History.—Development of disease succeeded an attack of grippe; troublesome cough; aphonia; loss in weight and strength. Came to Denver in March, 1898.

Examination soon after arriving in Denver. No distinct lung lesion detected; laryngitis; aphonia; very little expectoration, and no bacilli found. Weight, one hundred and forty-six pounds. I advised a tuberculin test, and obtained a distinct reaction with five milligrammes.

Began serum March 17, 1898; treatment continued three months and a half; cough and expectoration ceased; aphonia disappeared at end of second month. At close of treatment patient felt well and strong; no relapse to date. Present weight, one hundred and sixty-two pounds.

CASE IX.—Mr. M., aged thirty-three years; nativity, Ohio.

Family History.—Distinctly tuberculous on father's side.

Personal History.—Clerk; resident of Colorado several years; had pneumonia in December, 1896; health poor since; cough and pain in lungs, with expectoration; examination revealed no distinct lung lesion. There was, however, marked rough breathing in right lung; no bacilli found. Weight reduced from one hundred and forty-five to one hundred and thirty-three pounds.

Began serum October 16, 1897; continued one month; improved; gained four pounds; felt better and stronger; continued to gain in weight and strength for several months after stopping treatment; health good to date.

CASE X.—Mrs. M., aged twenty-three years; nativity, England.

Family History.—Tuberculous on mother's side.

Personal History.—Has lived in Colorado eleven years; gives history of so-called scrofulous diathesis. Began to fail in health after her first confinement (April, 1898). Evidence of lung disease developed in September, 1898. Cough; pain in lungs; rapid pulse, and afternoon fever.

Examination, October 20, 1898.—Slight dullness and a few râles in infraclavicular region of each lung; expectoration moderate, but no bacilli were found. October 26, 26 P. M., gave one milligramme "O. T." Temperature, 98.2° F.; pulse, 92. Patient became excited and depressed; nauseated; chilly at intervals at her shoulders stiff; temperature increased one degree and pulse accelerated. Obtaining this reaction from the initial tuberculin test, I decided to begin serum. Began October 26, 1898.

Weight on beginning serum, one hundred and eleven pounds; weight six weeks later, one hundred and eighteen pounds. Has gained strength, is feeling better, cough has ceased; no sputum; pulse and temperature normal; present state of health better than for years; treatment continued.

CASE XI.—Miss H., aged twenty-three years; native, New Jersey.

Family History.—Tuberculous on mother's side.

Personal History.—Opera singer. Health good until spring of 1898; trouble began with severe cold, which left cough and persistent pain in lungs, hoarseness, and occasional aphonia. Loss in weight and strength. Came to Colorado in May, 1898; experienced very little improvement.

Examination, August 1, 1898.—Slight infiltration in lower lobe of right lung; also distinct râles heard at last part of inspiration; dullness over third intercostal space in left side and along lower border of left lung in axillary region. Râles abundant over affected regions; also tenderness on percussion. Lung expansion, two inches and a quarter; weight, one hundred and fourteen pounds; pulse: sitting, 80; standing, 98; temperature, 98.4° F.; very little expectoration, and no bacilli found. Tuberculin test not made.

Began serum September 3, 1898; continued its use four months; marked improvement; gained four pounds; lung expansion, four inches—a gain of an inch and three quarters; infiltration of right lung diminished; tenderness over left lung absent; fewer râles; voice stronger; cough less; pulse and temperature normal; treatment continued.

CASE XII.—Miss M., aged thirty-two years; native, Germany.

Family History.—Negative.

Personal History.—Journalist. Had pneumonia eleven years ago; previous health excellent; cough and pleural adhesions supervened; has been in United States greater part of the time during ten years; cough and pleurisy pains continued; spent one year in Dr. Loomis's sanitarium. Cough continued until she came to Colorado in 1893; since then it has been less, and absent much of the time; no pain in lungs since coming to Colorado.

During the past year health has been gradually failing. In December, 1897, cough ceased and lung affection had apparently disappeared. Soon after the lung symptoms disappeared bowel symptoms appeared and rapidly became worse. In May, 1898, operation performed for appendicitis; slow recovery; health failed rapidly after operation; weight reduced from one hundred and forty-eight to ninety-eight pounds.

Patient experienced periodic attacks of dysentery, with tenesmus, general abdominal tenderness, and tympanites at intervals of ten days or two weeks. These attacks usually continued three days, and were frequently preceded with slight chills. This condition had existed several months, recent attacks increasing in severity.

Patient consulted me early in October, 1898, and remained under my observation several weeks, during which time I was unable to find a definite cause for her condition. Her principal trouble seemed to be intestinal. Temperature never far from normal, and frequently subnormal. Pulse about 90 and weak; no cough or expectoration; no pain in lungs; no leucocytosis. October 27, 1898, the urine and feces were examined for tubercle bacilli with negative results; examination of lungs also negative. Notwithstanding these negative results I suspected concealed foci of tuberculous infection and advised a diagnostic test of tuberculin, but patient objected. I saw the patient frequently and examined her lungs again November 9, and detected râles in apex of each lung. I again advised tu-

berculin test, and patient consented. On November 9, 11.45 A. M., the initial dose of one milligramme "O. T." was administered. Temperature, 98.4° F.; pulse, 84; respiration, 28. The injection was followed by a pronounced reaction. During the afternoon patient was nervous and experienced tingling sensation in limbs; cough commenced; headache, backache, and profuse perspiration during the night.

Next day, November 10, 1.45 P. M., temperature, 101° F.; pulse, 106; respiration, 35. I considered this reaction, following the minimum dose of tuberculin, sufficient to confirm my diagnosis of tuberculosis. On the following day commenced administering "antiphthitic serum, T. R." This treatment has been continued with the following results: The bowel trouble has gradually improved; less tympanites; less pain in bowels; appetite better; sleeps much better; less headache; patient in every respect feels better and is gradually improving. There has been no cough or expectoration at any time since beginning the serum.

It should be noted that I have been unable at any time to discover bacilli. Notwithstanding this fact, the patient responded to a marked degree to the tuberculin test and is making unmistakable improvement under the serum. Treatment continued.

It is generally thought that a condition of lowered vitality or diminished resisting power of the patient exists previous to the actual recognition of tuberculosis. Furthermore, it is conceded that injured, weak, or feeble tissues furnish a favorable seat for the primary tuberculous lesion. It is also well known that many other diseases fertilize the soil for the development of tuberculosis. Notwithstanding these facts, statements are frequently made which cast doubt upon the idea of a "pretuberculous state," or a "tuberculous predisposition."

By using the term "tuberculous predisposition" it is not intended to convey the impression that bacilli are present, or that foci of infection have already been established. There may, however, be lesions in the form of abrasions of the bronchial, laryngeal, or intestinal mucous membrane which serve as fertile culture media should bacilli come in contact with them; should this occur, rapid development of tuberculous lesions would soon follow.

My meaning is that there is a well-defined lowered resisting power of the organism which exists before tubercle bacilli can gain a lodging in the tissues. Such a state, however, need not necessarily terminate in tuberculosis, but the patient may succumb to other infectious diseases.

It should be observed that in each of the foregoing cases there was a strong tuberculous family history. Each patient had developed many of the symptoms of incipient tuberculosis and had been in a state of impaired health a considerable time. And, furthermore, the majority of the patients in this class had been in Colorado a sufficient time to test the climate, with little or no improvement. And, finally, the serum treatment was used unaided by other therapeutics, with the uniform

results reported—namely, the condition existing before beginning the serum was corrected, and, with but one exception (Case IV), they have remained in good health to date.

Having my experience with the serum before me, I am more than ever strengthened in my belief in the "pretuberculous state," and this state is accompanied by a deficiency in the antitoxic generating power of the blood and tissue cells. And, furthermore, that the "antiphthisis serum, T. R.," administered at this time, supplies the deficiency and enables the organism to regain its normal power. It is, however, of little importance by what name this state or condition is called. The important fact remains that a subnormal condition exists for a shorter or longer period previous to actual tuberculous infection. I believe, therefore, that the time is near at hand when prophylaxis will be considered of as great importance as therapy. It is for the purpose of emphasizing this point that I include the foregoing cases in my report.

(To be concluded.)

BATHING A REGIMENT.

By H. M. COHEN, M. D.,
ACTING ASSISTANT SURGEON, U. S. ARMY.

THE maintenance of the health of troops in the field has for many centuries put to the test the ingenuity of the ablest medical and military minds.

There is nothing that so much demoralizes a command as sickness. Often defeat in battle will be taken as a matter of course and stimulate the men to greater enthusiasm for further conflict. But once let a body of troops be attacked by disease, and even the strictest military discipline will not avail to prevent the command from undergoing rapid demoralization. It is said of Napoleon that before the battle of Waterloo he called a council of his medical advisers to learn the number of men unfit for duty. When he was informed that there were many who had been wounded in battle, he replied: "I care not for them, they have done their duty. What of the sick?"

Lord Nelson is given credit for the remark that "a sick sailor is worse than a dead sailor; for a dead one we bury and that is the end of him, but the sick one fears death and retards our progress."

Every known means has been resorted to in an effort to keep troops in a good healthy condition. At a regular permanent post, where barracks are furnished and all modern means are at hand, this is not such a difficult matter. But with troops in the field it is quite different.

Where a command is expecting to be ordered away at almost any moment, things of necessity are of a transient character, and must needs be incomplete.

Then, again, it is much easier to keep a few hundred men healthy, as at a regular post, than an entire division

or army corps in one large camp. It is therefore a commander's greatest object to keep all the men under him in as healthy a condition as possible, and to that end experience has taught every one that cleanliness is the greatest possible factor.

When a camp is about to be selected, the first consideration is that of the water supply. Experience has taught the army that there should be not only a plentiful supply of good, pure water for drinking purposes, but a sufficient quantity for bathing purposes. To this end, in camps of instruction, a system of water pipes is laid over the entire camp, thus making the obtaining of water an easy matter and the water accessible to all.

But, even with a very abundant supply of good water, it is very difficult to get the men to bathe thoroughly. This is not so much due to any inclination they may have toward uncleanness, as it is to the lack of proper facilities. Where the camp is near a stream, in the summer season all the men are only too glad of the opportunity to take a swim; and, realizing the good derived from this practice, the company commanders march their commands in a body to the river for that purpose. But in the cold seasons of the year this is impossible, and then it is that the men will habitually shirk the use of water for bathing purposes, and it is a most difficult matter to get them to observe proper cleanliness.

With this fact in view, various means and devices have been resorted to. One regiment at Camp Meade carried with it a number of tubs, all of different sizes, so that when a change was made they could be easily moved. These were used every day by a different company. By this method the difficulty was partially overcome, but it was far from satisfactory. In some regiments a tent was set aside for bathing purposes. It was the ordinary hospital tent and was heated by oil stoves. In this tent there would be several tubs, and each man desiring a bath would carry his own water. This was very unsatisfactory also. Various similar means were used, but with like results.

But at last a way has been found that makes bathing not only easy but an actual pleasure. For this, credit is due Major Edwin Field, the senior surgeon of the Fourth New Jersey Volunteer Infantry. The arrangements are somewhat as follows: A frame one-story shack is constructed that will accommodate about twenty men at one time. This place is divided by a partition into two rooms, so that one can be used for dressing purposes. At different places in the ceiling project pipes which scatter the water in all directions, thus making the shower bath. By means of a simple valvular arrangement the temperature of the water is easily regulated from hot to cold. The rooms are kept comfortable by an ordinary Sibley stove in the dressing room.

Outside of the shack is the furnace. This is a very simple arrangement and keeps the water at the proper temperature. It is constructed of brick, very much in

the shape of a bake-oven. Instead of a grate there are several coils of pipe through which the water passes, and is thus kept constantly warm.

The cold water comes through a different pipe which can be admitted into the main channel as needed. Thus, in the simplest way the water is kept at the proper temperature.

Two men are detailed to look after the arrangements and keep the furnace in good working order. Certain days are set apart for the different parts of the regiment. Each battalion uses the bath two days a week, thus taking six days. Sunday and three nights are set aside for the use of the officers.

Although these rules govern the outfit, the men can bathe two and three times in the week, and the great majority of them do. They invariably refer to the bath with the greatest enthusiasm, and they will tell you that it is the pleasantest function of the army routine.

To make sure that all men of the command get the benefit of at least one good bath a week, a registry is kept, and every man is required to have one to his credit when the week ends.

The actual cost of the whole outfit is comparatively small, the entire amount being less than two hundred dollars.

I have no doubt that the remarkably good health of this regiment is in a great measure due entirely to this one bath house.

The experiment has been closely observed and has received the hearty approval of all.

THE TREATMENT OF CHRONIC ULCERS OF THE LEG.

By JOHN B. CORSIGLIA, M. D.

IT is a mistake to imagine that in order to be a good surgeon one must necessarily be provided with the endless variety of instruments to be seen in the instrument-maker's window, or that in order to apply a truly antiseptic dressing one must have mastered the interminable list of chemical substances that are more or less endowed with germicidal properties. This sort of surgery can be practised only by a very few fortunate persons, and, if it were necessary, we should be obliged to consider the practitioners in the country and small towns, who by much simpler means obtain such frequent and remarkable results, as common bone-setters. Although in some cases it may be desirable to modify and perfect one's instruments, it is true that simplicity is the aim to be attained in surgery, and that great merit consists in knowing how to derive the greatest amount of benefit from the elementary means which one can easily manage.

From my personal experience, I have come to the conclusion that this is especially true in the treatment

of chronic ulcers of the leg. The chronic-ulcer patient is like the unfortunate sufferer from chronic specific urethritis. If he is a well-to-do man he is forever hunting up specialists. If he is poor, there are no hospitals or dispensaries in the city which he has not visited; and the consequences are that such a patient frequently carries his troubles to the grave. But if, after a great deal of persuasion on some physician's part, he is finally convinced that his trouble is not a mere *bagatelle*, that a speedy cure can not be effected, and that he is doing himself wrong by drifting from one doctor to another, he very soon regrets that he did not follow this advice before.

And while I do not wish to bring criticism upon my colleagues, yet I must say that I have observed so many forms of ointments, such promiscuity of treatment adopted in chronic ulcers of the leg that, although the lack of the patient's confidence in his physician has a great deal to do in increasing his misery, yet I firmly believe that often if simpler treatment were adopted in these cases the quicker and better would be the results.

Let us take, for instance, a chronic ulcer situated below the middle of the leg. I first scrub the leg and ulcer with soap and water, and dry thoroughly. No matter what kind of an ulcer it is, my next aim is to reduce it to a simple ulcer. This is done by curetting; and, as this is quite a painful procedure, I inject two or three drops of a four-per-cent. solution of cocaine in the vicinity of the ulcer. The best mode of using cocaine hypodermically is to put the needle in superficially and horizontally as far as it will go. After two or three minutes, during which anesthesia appears, I inject two or three drops more with deep punctures. If much bleeding results on curetting, I dip a sponge in a two-per-cent. solution of carbolic acid and compress for five or ten minutes. If at the end of this time bleeding continues, I leave on a wet dressing of said solution for twenty-four hours. My next aim is to get the ulcer dry, and to dress it dry. I have obtained the quickest results by brushing the ulcer with pure carbolic acid, and then touching this with a little cotton dipped in alcohol. Alcohol has the power of absorbing carbolic acid, and so lessens the action of this drug. If at the end of two days I still find any oozing, I again brush with pure carbolic acid. In regard to the bandage, I begin at the toes and extend up as far as the knee. And let me say just here that a properly applied bandage is of the utmost importance in these cases. When the ulcer is perfectly dry, I apply small pieces of adhesive plaster heated over an alcohol lamp, one piece overlapping the other, and allowing a small space between for any discharge which might take place. After a few days, if no exudation is seen on the dressing, and there is no displacement, I leave it on for a week or two. Of course, each case is a law in itself. But, no matter how old the ulcer may be, I have as yet to see the one which would not yield to this treatment. In varicose ulcers,

where the ulcer is surrounded by a thick ring of tissue, I make radiating incisions. By so doing, you start the circulation toward the dead part, and so give the ulcer a chance to heal. In these cases also, and where extensive œdema is present, the bandage should be pretty tight; if cellulitis complicates these cases, I order an elastic bandage.

Practitioners will find the utmost difficulty in obtaining any history in many cases. But I have laid down this rule: An ulcer situated above the middle of the leg is syphilitic, regardless of history. I make it a rule to examine the heart, lungs, and kidneys in all cases, as disease of any of these organs would interfere in the local treatment. For instance, if the heart is diseased, passive congestion and œdema of the lower extremities are of frequent occurrence. Proper attention, then, to this organ, when compensation is possible, will greatly facilitate you in getting rid of the ulcer. But simplicity, cleanliness, and the proper time of interference are the sheet anchor in all cases. And as to drugs, I have as yet to find the one which will equal pure carbolic acid.

50 CENTRE STREET.

GONORRHOÆAL VAGINITIS AND ITS TREATMENT.

By HARRY GREENBERG, M.D.,

INSTRUCTOR IN GYNECOLOGY,
WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS, MILWAUKEE.

GONORRHOÆAL infection, as an ætiological factor of most pelvic troubles, is now well recognized by men of large experience, and even the most conservative admit of its frequent relationship. Therefore, the proper treatment at its onset, and the prevention from its attacking neighboring organs, I consider better surgery than the skillful removal of pelvic organs, with its accompanying large fee and great glory.

That gonorrhœa in women is at present improperly treated, one has but to attend large gynecological clinics and witness the wholesale mutilations of the pelvis in so many women, to be convinced.

The natural sequence of gonorrhœal vaginitis not treated or improperly treated is but its gradual extension, following the mucous tract, from vagina to cervical canal, to uterine canal, Fallopian tubes, ovaries, and peritoneum.

The gonococci, unlike other pyogenic organisms, do not penetrate the muscular wall, but follow along the mucous canal, and are therefore not so immediately dangerous to life as the staphylococci or other pus-producing bacilli.

The cause of gonorrhœa is contact with gonorrhœal pus, whether it is by coitus or indirectly by means of rags, etc., saturated with gonorrhœal pus, or, in a child, by sleeping with an uncleanly gonorrhœal mother, whose

discharge is carelessly allowed to come into contact with the vulva of the child.

The diagnosis offers no difficulties. A woman, having been previously well, who, shortly after marriage or indulgence with her lover, begins to feel pain in her pelvis, with burning and frequent micturition and a discharge of a thick, yellowish matter, with painful, profuse, and irregular menstruation, has a typical case of gonorrhœa. On inspection the parts look red, inflamed, and covered with a thick, tenacious, mucopurulent discharge, and the urethral orifice looks red and eroded. On introducing the index finger into the vagina up to the neck of the bladder and carefully withdrawing it, causing a continuous pressure on the anterior vaginal wall along the course of the urethra, a drop or more of pus will ooze out from it. Speculum examination will show that the cervical os, on first inspection, is thickly covered with a stringy and tenacious pus which can be removed only with difficulty. The odor of the gonorrhœal discharge is also peculiar to itself, and once encountered is always remembered if one is endowed at all with sensitive olfactory filaments. Such typical cases we do not, however, always meet with, and fortune usually smiles on the beginner, or the inexperienced, by sending him the atypical, or the subacute and chronic, with leucorrhœa, menorrhagia, and dysmenorrhœa as symptoms complained of, with painless urination and no history of exposure to infection. With the squeezing out of a drop or more of pus from the urethra, the stringy, tenacious, and purulent character of the discharge, and the microscope, a definite diagnosis can and should be made in the interest of humanity and the preservation of the organs of the female pelvis.

Once diagnosticated, the enemy should be located and attacked. There should be no leniency, no work on suppositions. Gonorrhœa is a local disease, and the tissues attacked are those that suffer, and whatever constitutional symptoms may then exist are due to reflex action caused by the saturation of the terminal nerve fibres with gonorrhœal pus.

To cure gonorrhœa the gonococci should be killed locally. Constitutional remedies have no effect, except as a palliative, to whatever reflex disturbances there may then exist. To cure the disease means also to prevent its spreading, in which the great danger lies.

The enemy on the open—that is, the gonococci in the vagina—may be conquered with effective weapons. Once they are entrenched and barricaded in the uterine canal, with a fertile soil to thrive on and monthly harvestings, which menstruation affords, our power of attack becomes limited or null. The further extension of the disease into the unprotected tubes is now left unhindered, and results in pyosalpinx. If the oviducal mouths become occluded by inflammatory exudates, sterility, with its accompanying dysmenorrhœa, menorrhagia, etc., is the result. If they remain open, pus enters the peritoneal cavity and produces local peritonitis. Marriages are

universally the result if impregnation takes place; the ovum can not successfully thrive on a diseased endometrium, or it is directly attacked by the gonococci and killed.

Over two hundred cases of gonorrhœal vaginitis, the complete records of which are now in my possession, have led me to regard the disease with the utmost respect, and not to think lightly of it until wholly conquered. But, thanks to vigorous treatment, together with the aid of the patient, whose confidence and intelligent understanding of her ailment are so essential to success, much can be accomplished in completely curing the disease.

Rest in bed I consider indispensable in an acute attack, and almost always insist upon it. The diet should be light, and alcohol in any form strictly forbidden. Purity of thought should be enjoined. Allow nothing which will directly or indirectly tend to irritate the parts affected.

Cleanliness is next in importance, as it affords greater resistance to the tissues attacked and prevents the invaders from accumulating and multiplying. Keep them reduced in number. Sitz baths of warm water with sodium bicarbonate, twice daily, and with two hourly douches of sodium-bicarbonate solution, a gallon each time, will answer the purpose effectively.

The sodium bicarbonate acts as a sedative rather than as a germicide. To kill the gonococci, once a day, after the morning sitz bath and douche, the vagina should be thoroughly scrubbed by the physician, with soap and water and a soft nailbrush. A speculum should be introduced and the tenacious and sticky pus from the cervix mechanically removed; the folds of the vagina should now be put on the stretch by the gradual withdrawal of the bivalve speculum and a 1-to-1,000 bichloride solution, or, better still, five-per-cent. pyocetanin (methylene blue) thoroughly applied by means of cotton on an applicator.

What I particularly wish to emphasize is the necessity of stretching the vaginal folds to apply the germicidal solution, also the frequent use of the douche and the quantity of water employed. A gallon every two hours I do not consider too frequent or too much.

545 EAST WATER STREET.

REPORT OF A CASE OF ACCIDENTAL SWALLOWING OF A BRASS WIRE, AND ITS SPONTANEOUS ESCAPE FROM THE STOMACH BY WAY OF THE NINTH INTERCOSTAL SPACE.

By WILLIAM J. GILLETTE, M. D.,
PROFESSOR OF ABDOMINAL AND CLINICAL SURGERY,
TOLEDO MEDICAL COLLEGE;
SURGEON TO ROBINWOOD HOSPITAL, TOLEDO, OHIO.

On the 10th of September, 1898, Dr. C. A. S., while swallowing his throat with a prolapsed end of brass wire, No. 2, six inches in length, the end of which was wrapped with cotton, accidentally allowed it to slip

out of his fingers, when it passed down the œsophagus beyond his reach.

An hour later Dr. G. F. Suker saw the patient, and upon examination could feel the upper end of the probang in the region of the cricoid cartilage, but failed to remove it, as it seemed imbedded in the anterior wall of the œsophagus.

I saw the patient soon after, but advised that nothing be done unless the wire gave trouble. I could at this time find no evidence of its presence in the œsophagus. The patient suffered not the slightest discomfort, and did not for nearly three months, when he began to have distress in the epigastrium. On the 9th of January, 1899, he experienced a good deal of sharp pain in the region of the cardiac end of the stomach, and the next day the end of the probang was found protruding under the skin in the ninth intercostal space near the costal cartilages.

He was admitted to Robinwood Hospital on January 11th, and on the 12th a four-per-cent. solution of cocaine was injected around the point of presentation, and a small incision of the skin was made, when the end of the wire was readily grasped with a forceps and the wire removed.

The patient remained in the hospital a few days, suffering not the slightest annoyance from the small operation performed, when he was discharged.

A number of cases have been reported of the escape of foreign bodies from the stomach through the abdominal wall, but I am not aware that any have been heretofore reported where the foreign body escaped by way of the thoracic wall.

705 MADISON STREET.

Therapeutical Notes.

Ryerson's Cleansing Solution for the Nasal Passages.—Dr. G. Sterling Ryerson, of Toronto (*Canadian Practitioner and Review*, February), devised the following solution in 1884, and has used it ever since with satisfactory results:

R Sodium bicarbonate,	} each.... 30 grains;
Sodium baborate,	
Sodium chloride,	
Sodium salicylate.....	
Oil of bergamot.....	40 "
Listerine.....	3 minims;
Glycerin.....	½ ounce;
Distilled water, enough to make.	1 "
	8 ounces.

M.

Pastilles for Fœtor of the Breath.—This formula is given in the *Journal de médecine de Paris* for January 15th:

R Powdered coffee.....	45 parts;
Vegetable charcoal,.....	} each..... 15 "
Powdered sugar,.....	
Vanilla,.....	
Mucilage of gum arabic.....	a sufficiency.

M. Divide into pastilles of fifteen grains each. Five or six to be chewed daily.

Picric Acid in the Treatment of Gonorrhœa.—Antonelli and Scatolari (cited in the *Klinisch-therapeutische Wochenschrift* for February 26th) inject

three times a day, in cases of acute gonorrhœa, about a pint of a filtered two- to five-per-cent. solution of picric acid, with the reservoir elevated from three to five feet above the urethra. These irrigations are said to be very soothing, and often to effect a cure in two weeks.

A Formula for Iron and Cinchona.—The *Gazette hebdomadaire de médecine et de chirurgie*, February 26th, citing *Nouveaux remèdes*, attributes to Dr. Patier the following formula based upon the solubility of tannate of iron in glycerin:

- R Tartrate of iron and potassium 150 grains;
 Extract of cinchona 150 "
 Glycerin 300 "
 Distilled water 150 "
 Madeira wine, enough to make one quart.

The Treatment of Exophthalmic Goitre.—The *Riforma medica* for February 10th attributes the following to Kant:

- R Sulphate of duboisine $1\frac{1}{3}$ grain;
 Water 75 minims.

M.

To be taken two or three times a day.

Compound Iodoform Powder for the Dressing of Uterine Ulcers.—The *Gazette hebdomadaire de médecine et de chirurgie* for February 19th gives the following:

- R Finely sifted iodoform,
 Powdered cinchona,
 Powdered benzoin,
 Powdered carbonate of } of each, equal parts.
 magnesium saturated
 with essence of eu-
 calyptus. }

M.

For Laryngeal Inhalation.—According to the *Gazette hebdomadaire de médecine et de chirurgie* for February 19th, Didsbury is responsible for the following:

- R Tincture of benzoïn 60 grains;
 Tincture of eucalyptus 60 "
 Tincture of soapwort 90 "
 Cherry-laurel water 150 "
 Distilled water 3,750 "

M.

Two inhalations of five minutes each daily.

The Treatment of Tubercular Cystitis.—The *Clinica moderna* for February 8th gives the following:

In the first stage—viz., before surgical intervention is called for—it is requisite to combat the purulence of the urine and the pain. To that end one of the following formulae may be used:

- R Sulphate of codéine $4\frac{1}{2}$ grains;
 Salol 90 "

Divide into twenty powders.

Sig.: One powder to be taken after each meal.

Or,

- R Hydrochloride of cocaine,
 Extract of cannabis in } of each, 43 grains.
 dia,
 Carbonate of guaiacol 30 "

M.

Make twenty pills. One pill to be taken after every meal.

Against fermentation of the urine urotropin may be

given in a dose of four grains and a half four times a day.

Creosote in Constipation.—The *Medical Review of Reviews* for February 25th, citing the *West London Medical Journal* for October, says that creosote may be administered in drop doses, twice daily, after breakfast and dinner, for constipation. It should not be prescribed in capsules or pearls, but should be taken in milk, beer, wine, etc. After a few days the dose should be gradually increased to seven minims twice daily.

For Acute Otitis.—The *Gazzetta degli ospedali e delle cliniche* for February 14th recommends:

- R Ichthyol 15 grains;
 Glycerin, } of each $112\frac{1}{2}$ "
 Distilled water, }

M.

A few drops of this mixture to be dropped three times daily into the ear.

The Treatment of Eczema of the Hands.—The *Gazzetta degli ospedali e delle cliniche* for February 14th gives the following formula:

- R Pure iodine $1\frac{1}{2}$ grains;
 Iodide of potassium $3\frac{3}{4}$ "
 Glycerin 150 "

M.

To be applied in the evening, and in severe cases twice daily also.

Ichthyol in the Treatment of Fissure of the Anus.—The *Gazzetta degli ospedali e delle cliniche*, for February 7th cites Van der Willigen and Conitzer (*Münchener medicinische Wochenschrift*, 1899, No. 3) as having used ichthyol successfully in the treatment of rhagades of the anus. It is applied pure. At first it is well to anesthetize the part with cocaine, but subsequently there is little or no need of this.

Oily Collyria.—At a recent meeting of the Paris Academy of Medicine (*Progress médical*, January 28th) M. Sorini insisted on the advantages of oil as a solvent of alkaloids for ophthalmic use. Oily solutions, he said, were better borne and more efficient than aqueous collyria.

Resorcin in the Treatment of Granular Pharyngitis.—Lyon (cited in the *Gazzetta degli ospedali e delle cliniche* for February 9th) employs the following gargle in the acute stage:

- R Resorcin 4 parts,
 Glycerin 15 "
 Distilled water 150 "

M.

A Topical Application for Acute Articular Rheumatism.—The *Revue médicale* for January 31st gives the following formula:

- R Extract of hyoscyamus 5 parts,
 Iodoform 10 "
 Sodium salicylate 30 "
 Vasoline 100 "

M.

Orexine in the Vomiting of Pregnancy.—Hermann, impelled to the trial by Frommel and Rich's reported results (*Pharmaceutisch Mittheilungen*, January, *Presse médicale*, February 11), has used orexine in these cases, successfully in every instance. Dose, four grains two or three times a day.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, MARCH 25, 1899.

PROFESSOR OSLER ON TYPHOID FEVER IN THE
UNITED STATES.

PROFESSOR WILLIAM OSLER, of Baltimore, a man who never speaks or puts pen to paper without communicating ideas of weight in words of beauty, recently delivered before the Medical Society of the State of New York an address entitled *The Problem of Typhoid Fever in the United States*. The address has appeared in the *Medical News* and, we think, in some other journals, so it will be read by many medical men. Nevertheless, Dr. Osler has added to his numerous benefactions to the American people by having it printed also in the form of a very attractive pamphlet.*

The address reminds us, in the first place, of some things we are too apt to forget—the brilliant labors of Nathan Smith in the study and portrayal of typhoid fever in the early part of the century, and those of Elisha Bartlett, James Jackson, Jr., W. W. Gerhard, George C. Shattuck, Alfred Stillé, and Austin Flint, in this country, and Sir William Jenner, in England, at subsequent periods. Speaking of Nathan Smith's *Practical Essay on Typhous Fever*, published in 1824, Dr. Osler says he re-reads it at intervals, each time with increasing respect for the author's sagacity. "There is," says Dr. Osler, "more strong, sane sense in his booklet of 85 pages than in anything that had appeared on 'the slow nervous fever' sincefluxham. It is most refreshing to turn from contemporary treatises on fever in English, French, and German to this clinical masterpiece. Happy the patients who fell into the hands of the old founder of Dartmouth Medical School and the first professor of medicine at Yale! With but little modification his section on treatment might be transferred to one of our year-books as the freshest and the best."

The American medical profession may justly look back with pride to the pioneer work it did in elucidating the subject of typhoid fever, but another picture, one by no means so pleasant to contemplate, is shown further on in Dr. Osler's address—that, namely, of the almost complete disregard shown by the American people in their collective capacity of the labors of American

physicians of our own times to stamp out the disease by cleansing the soil and purifying the drinking-water. Our shameful hygienic shortcomings are eloquently shown up in Dr. Osler's address, and we hope that his appeal will not fall on barren ground.

THE BEGINNING OF THE END FOR DIPLOMA MILLS
IN ILLINOIS.

IN our issue for February 18th we published the substance of senate bill No. 172, introduced by Mr. Chapman on February 2d, designed to put a stop to the career of diploma mills in the State of Illinois. It was in the form of an amendment to the law of April 18, 1872, concerning corporations. The bill was referred to the committee on judiciary. We now learn that on the 15th of March that committee recommended the passage of the bill with some minor amendments. It is generally known as the State board of health bill, and its purpose is to confer on the secretary of State power to revoke the charters of institutions granting degrees in medicine, pharmacy, or dentistry, on presentation to him by the State board of health, the State board of pharmacy, or the State board of dental examiners of proof that such institutions are conducting a fraudulent business. Among the changes proposed, we understand, is that of vesting the licensing power in the attorney general instead of in any of the boards mentioned.

So far as we are informed, the State board of health does not object to this change, and it is confidently expected that the bill, if it becomes a law, will put a stop to the diploma mills. So high an officer as the attorney general may, it is assumed, always be depended upon to do his duty in the interest of the community. The Illinois profession seems to feel this confidence, and we have no doubt it is justified. Incidentally, we take pleasure in recording the fact that the charter of the Independent Medical College, of Chicago, has been revoked by a court. A motion for a new trial and one for arrest of judgment were overruled, but an appeal to the supreme court was allowed.

CASE OF RUPTURE OF THE BLADDER WITH
SPONTANEOUS CURE.

DR. DRAPPIER records in the *Journal des sciences médicales de Lille* for December 10th a case which strikes us as being sufficiently extraordinary to deserve special mention. A laborer leading his horses to water was mounted on one of them, when suddenly the horse shied and threw him down among the others. He was trampled upon and received, among other injuries, a violent contusion in the hypogastric region. Before

* Loaned by the John Murphy Company, Baltimore.

mounting he had felt a great desire to urinate, for he had been drinking somewhat, but he had not complied with the desire. When Dr. Drappier saw him, an hour later, the hypogastric region was exquisitely tender and slightly swollen, but from pubes to umbilicus in place of dullness there was marked resonance. A little blood trickled from the meatus urinarius, and an elongated clot of about the calibre of the urethra was passed after violent efforts made by the patient to urinate. The vesical tenesmus persisted after the passage of the clot, and, notwithstanding that it was many hours since the patient had urinated, no urine escaped. A flexible catheter was then introduced into the bladder, but failed to withdraw any urine; so a three-per-cent. solution of boric acid was injected in small quantities until about a pint had been passed in. None of it returned. Dr. Drappier summoned his colleague with a view to deciding what operative intervention was requisite, and meanwhile applied opiated poultices to the hypogastrium. In about half an hour the pains were greatly lessened, and on the arrival of assistance the patient was sleeping quietly. When he awoke the abdomen was less tender, and he passed a small quantity of sanguinolent urine. It was decided, therefore, to await results, and the patient was told to urinate if possible every two hours, since he objected to a catheter being tied in, and was given thirty grains of salol. Six or seven hours later he was sitting up, urinated without difficulty, the pain was bearable, the general condition good, and the pulse normal, while the swelling had disappeared. Milk diet was given, and a drachm of salol was administered daily. In two days the patient was able to walk a little, and in five days he was discharged cured.

The questions for consideration are as to the fact of a rupture of the bladder, its extent and seat, and the method of cure. The emptiness of the bladder on catheterism, seeing that the man had not micturated for many hours, tends to establish the fact of a rupture. That the failure to obtain urine was not due to the catheter's not reaching the bladder is proved by the subsequent introduction of a pint of boric solution, not a drop of which returned. Further confirmation is found in the tenesmus, the disappearance of the vesical dullness, and the presence of blood in the urine.

As to the seat of the rupture, doubtless careful exploration with the metallic sound, combined with hypogastric palpation and rectal examination, would have demonstrated this. But in view of the rapid amelioration such interference would have been indefensible. For various reasons, however, it would appear that the rupture was in the posterior superior portion of the bladder: 1. The absence of puffiness in the hypogastric

region, which would have existed had the rupture been anterior. 2. The patient's position in the dorsal decubitus would surely have left some of the boric solution in the bladder had the rupture been anywhere but in the most dependent portion of that viscus. 3. The anatomical structure of the bladder, the muscular fibres being less numerous and less thick in the upper part, thus rendering that the point of least resistance. Further, had the injury been in the lower part, the bladder would surely have emptied itself by degrees to some extent as the urine trickled down from the ureters.

The extent of the wound must be supposed to have been small, and, as the bladder was distended at the time of the accident, it probably emptied itself abruptly into the peritoneal cavity. Then the walls retracting, the edges of the wound fell into contact and, no further distention taking place, finally united.

The most noteworthy point is the absence of peritoneal infection. The experiments of Tuffier, who asserts that he has demonstrated the innocuousness of aseptic urine to the peritoneum and its rapid absorption by that membrane, would seem to receive additional confirmation from this case. In his opinion, it is not the urine itself, but its continued effusion, which is ordinarily the cause of peritonitis. The boric injections doubtless helped to render the urine innocuous in this remarkable case.

THE ANOMALIES IN BRITISH MEDICAL DEGREES: A CORRECTION CORRECTED.

The Journal of the American Medical Association for March 18th, replying to our comments on this subject in our issue for March 11th, takes exception on two points, accepting our correction, but adding that "the critic is also slightly incorrect." It is in no spirit of captiousness that we reply, but because we think that possibly some interest attaches, even on this side of the water, to the multifarious array of letters which the many English-qualified practitioners in this country are entitled to place after their names in addition to, or substitution for, the simple M.D. *The Journal* says: "There is an L.R.C.S. degree, etc." We did not dispute that fact, save in the case of the College of Surgeons of England, which does not grant a license, its membership being practically, though not theoretically, equivalent thereto. The L.R.C.S. is granted by the Colleges of Surgeons of Edinburgh and Ireland, while the Faculty of Physicians and Surgeons of Glasgow confers a license, abbreviated L.F.P.S. Glasg. None of these three colleges, however, grants a membership. Neither did we deny that the Colleges of Physicians of Edinburgh and Ireland, as well as that of London, grant a membership, though the Faculty of Physicians and Surgeons of Glasgow does not. We were speaking of surgical colleges when we stated that while the L.R.C.S. does correspond in surgery to the F.R.C.P. in medicine, "the English College of Surgeons had no" (surgical) "equivalent for the lower grade" (in medicine) "of L.R.C.P., while the Scotch and Irish colleges"

(of surgeons) "have no" (surgical) "equivalent for the intermediate grade" (in medicine) "of M. R. C. P." The insertion of the words here bracketed would, perhaps, have made our meaning clearer, though we think that the sense of the passage should be perfectly plain to a careful reader as it stood. The Royal College of Physicians of Ireland was formerly called the King's and Queen's College of Physicians, whence, in place of the present L. R. C. P. I., etc., there formerly existed the fearsome qualifications of L. (or M. or F.) K. Q. C. P. I. The qualifications of the Faculty of Physicians and Surgeons of Glasgow are L. F. P. S. Glasg. and F. F. P. S. Glasg. Licenses, memberships, and fellowships of colleges are not "degrees" from an English point of view, for such can only be conferred by universities. The case of the "Lambeth degrees" granted by the Archbishop of Canterbury does not affect this statement, since they are a remnant of the primate's pre-reformation office of legate from the Holy See, carrying jurisdiction over the universities, which were at that time ecclesiastical institutions. This is shown by the fact that the recipients of those degrees, which are granted in several faculties besides medicine, though in the latter instance only to legally qualified practitioners, are entitled to wear the academical costume of the corresponding degree in the university from which the primate granting it himself graduated, practically always either Oxford or Cambridge.

A RARE CAUSE OF SATURNISM IN INFANTS.

ROUSSEL (*Loire médicale; Gazzetta medica lombarda*, February 15th), in his clinic at the Hôpital St.-Étienne, observed quite a number of infants suffering from constipation, colic, and vomiting, the cause of which symptoms he was unable to fathom until he observed that the mothers were suffering from cracked nipples. Inquiry elicited the fact that an "application for sore nipples" was being used for the fissures, which, upon examination, proved to consist of a lead base. Although in the absence of teeth the gums did not show the slate-colored line of Burton, nor the inner surface of the cheeks the slate-colored patches of Gubler, etc., the author deems it fair to conclude that the syndrome of symptoms, taken in conjunction with the undoubted fact of the contact of lead with the infant's mouth, make the diagnosis of lead-poisoning beyond dispute. An inquiry into the question of applications to the nurse's breasts is, therefore, clearly indicated in cases of obscure colic and constipation in sucklings.

SMALL-POX.

OUTBREAKS of small-pox have been reported from a great number of places, both in the United States and elsewhere, during the last few weeks, and some cases have occurred in New York. They emphasize the importance of turning a deaf ear to the antivaccination agitators.

THE WINDSOR HOTEL DISASTER.

THE great loss of life and the large number of injuries that occurred in connection with the burning of the Windsor Hotel, on Friday of last week, are perhaps to be ascribed in part to the fact that Fifth Avenue, on which the building was situated, was blocked at the time with people who were watching the St. Patrick's

Day parade, thus delaying the access of the firemen and embarrassing them in their work. But this can not be taken as the chief cause. It is evident that the house was ill fitted to protect those who were in it against loss of life in case of fire, and we may remark that those who are teaching "first aid to the injured" might employ some of their time to advantage in teaching people how to slide down a rope properly.

THE ALL-NIGHT PHARMACY.

THERE is a shady side to almost every calling. Perhaps the all-night pharmacy is one of the most repugnant exemplifications of this fact, as set forth in Dr. Bicknell's letter printed in this issue, for it taints that aspect of the honorable pharmacist's career that is most apt to catch the eye of the public. The ordinary man, when made acquainted with the existence of such dens, is prone in his thoughtlessness to stigmatize apothecaries in general as a set of panderers to vice and weakness.

"HUSA."

SEVERAL months ago we mentioned some investigations of a mysterious plant called "husa," said to be found in the Everglades of Florida and vaunted as a cure for the opium habit, and subsequently we published a communication from the author of those investigations. We are glad to learn that Professor John Uri Lloyd, of Cincinnati, has examined into the subject and communicated his results in a paper read on March 15th at a joint meeting of the Cincinnati Section of the American Chemical Society and the Cincinnati Academy of Pharmacy. We hope soon to lay the substance of Professor Lloyd's conclusions before our readers.

THYROID PREPARATIONS CONSIDERED AS POISONS.

At a recent meeting of the Paris Academy of Medicine (*Progrès médical*, January 28th) it was noted, as the result of a report by M. François Franck, that, inasmuch as thyroid products were poisonous, no matter what their form, their sale should not be allowed, under the regulations for dangerous remedies, except on a physician's prescription, renewed each time. Such a regulation ought to be in force in the case of every potent drug.

THE RÖNTGEN RAYS IN THE TREATMENT OF CHRONIC ECZEMA.

If the application of the Röntgen rays is sometimes productive of unfortunate results, it is consolatory to find that it may, on the other hand, prove beneficial in certain morbid states. Dr. R. Hahn (*Fortschritte auf dem Gebiete der Röntgenstrahlen*, ii, 1; *Centralblatt für Chirurgie*, March 11th) reports two cases of eczema of the legs of very long standing in which a few exposures to the rays were followed by complete cure.

FORMALIN IN THE TREATMENT OF WHOOPING COUGH.

IN our issue for March 4th we published an article on this subject, by Dr. Howard S. Olliphant, of New Orleans. This article reminded Dr. R. E. Hinman, of Atlanta, of one of his own on the same subject, which appeared in the *New York Medical Times* for Novem-

ber, 1894. Dr. Hinman, it appears, used a one-per-cent. solution sprayed about the patient, whereas Dr. Olliphant employs one of five per cent. applied directly to the throat. Dr. Olliphant therefore thinks that his communication stands on an independent basis, in spite of Dr. Hinman's having antedated him in the use of the remedy for whooping-cough. We think both gentlemen are entitled to the credit of having made a genuine contribution to our therapeutical resources.

THE FOLLY OF PROTRACTED RECUMBENCY AFTER CHILDBIRTH.

At a recent meeting of the Lille Society of the Medical Sciences (*Gazette hebdomadaire de médecine et de chirurgie*, March 2d) M. Desplats brought up the question of the advisability of nine days' confinement to bed after parturition. It is not altogether a new one, but it was very forcibly dealt with by the speaker. He denied that getting out of bed was fraught with danger. On the contrary, he said, among the poor the woman got up at once, and generally she made a more satisfactory recovery than her more richly endowed sister. This, said M. Desplats, stands to reason, for it is with great difficulty that the uterine discharge, often on the verge of putrescence, escapes when the woman is lying down, whereas everything comes away freely when she assumes the upright posture.

ADDISON'S DISEASE IN A NEGRO.

At the *Société médicale des hôpitaux*, according to the *Gazette hebdomadaire de médecine et de chirurgie* for March 2d, M. Thibierge showed the unusual case of a negro, thirty-five years of age, a native of Oran, in whom the mucous membrane of the mouth showed numerous pigmented patches disseminated over the lips, cheeks, palate, and tongue, and answering to the description of the buccal pigmentations which are found in Addison's disease. The diagnosis was further confirmed by the fact that the patient's skin during the past three years had shown distinct darkening. During the same period the lumbar pains and the sensation of general asthenia associated with that disease had also appeared. The patient was, moreover, tuberculous. Whether the disease is rare in the negroes, or whether it is that the discoloration of the skin which is usually the first symptom calling attention to it, though by no means the first to appear, is difficult of observation in them, certainly recorded cases are by no means common.

OSTEOPLASTIC OPERATIONS FOR INTRACRANIAL DISEASE.

OVER-ENTHUSIASM on the subject of opening the skull for the relief of various morbid conditions within it is likely to be toned down very considerably by such judicious statements as those made by Dr. George Emerson Brewer at a meeting of the New York Neurological Society held on March 7th. Dr. Brewer reported that, out of from thirty to forty cases of intracranial disease that he had seen in the City Hospital during the last five years, nearly all of them in consultation with the neurologists of the hospital, sixteen had come to operation. Seven of the patients had been in fair physical condition at the time. In thirteen out of the sixteen cases a lesion sufficient to account for the symptoms had been found. In two instances the operation had undoubtedly saved life. In none of the cases that ter-

minated fatally had there been any possibility of improvement without an operation, and in five of them death would have occurred almost immediately. The operation had been the cause of death in two instances, by acute uremia in one case, and presumably by acute septic infection in the other. He was willing to admit that this sepsis might have been avoided. He thought it quite probable that nineteen twentieths of operations done for epilepsy were fruitless; nevertheless it was well to operate in the hope of occasionally saving a person from the life of an epileptic.

THE RIGHT TO TAKE THE STATE EXAMINATION IN NORTH CAROLINA.

THE *Southern Medical Journal* for March speaks approvingly of a bill recently enacted by the legislature of North Carolina which provides that an application for examination by the State medical board shall not be entertained unless the applicant produces satisfactory evidence of having graduated from a medical college in good standing, one that requires an attendance of not less than three years and supplies such facilities for clinical instruction as meet with the board's approval; but that a license or other satisfactory evidence of standing as a legally qualified practitioner in another State shall be accepted in lieu of a diploma, and entitle the applicant to be examined. We agree with our contemporary. Legal qualification in one State may well be accepted as entitling to the examination in another.

MALIGNANT TUMORS OF THE SUPRARENAL GLAND

DR. OTTO RAMSAY has contributed notably toward systematizing our knowledge of primary malignant tumors of the suprarenal gland, in an article published in the January-February-March number of the *Johns Hopkins Hospital Bulletin*. He finds that, while such growths are rare, their possible existence has to be taken into account in the diagnosis of abdominal tumors. In a certain proportion of cases the symptoms are fairly well marked, but there are many in which symptoms pointing to disease of the organ are wanting. Skin changes are rather exceptional. The course is more rapid than is usual with similar growths in other organs. The prognosis is always serious, the only hope of relief lying in an operation, which has been successful in two instances. Its chief difficulties are the friability of the tumor, the great tendency to hemorrhage, and the frequency of adhesions.

THE DANGER OF CERTIFYING TO LUNACY IN ENGLAND.

COMMENTING on a letter of The Unrestrained Lame-tic Danger, signed "Fairfax" and printed in the *St. James's Gazette*, the *Lancet* for March 11th states that many English medical men refuse to certify to a person's lunacy under any circumstances, because, in the event of the committed person's being subsequently set at liberty, he may bring suit against the certifier, who, even since the statute of 1890 came into operation, has to prove to the court's satisfaction that he acted "with good faith and reasonable care," a thing not always easy to do. Our New York State law, as we understand them, are certainly more liberal in this respect toward a certifying physician, so far as the possible ulterior consequences are concerned, although perhaps more vexatious in the first instance.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 18, 1899:

DISEASES.	Week ending Mar. 11.		Week ending Mar. 18.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	17	6	14	4
Scarlet fever.....	182	14	162	18
Cerebro-spinal meningitis.....	0	12	0	11
Measles.....	280	15	229	14
Diphtheria.....	11	5	171	30
Croup.....	11	5	8	4
Tuberculosis.....	178	202	131	169
Small pox.....	0	0	2	1
Chicken-pox.....	37	0	35	0

The Kentucky State Medical Society.—Dr. John G. Cecil, chairman of the committee of arrangements, announces that the next annual meeting will be held in Louisville, on Wednesday, Thursday, and Friday, May 17th, 18th, and 19th. All those who desire to take part in the proceedings are requested to send the titles of their papers at once to the secretary, Dr. Steele Bailey, Stanford, Kentucky.

The French Academy of Sciences.—We learn from the *British Medical Journal* that Professor Ray Lankester has been elected a correspondent of the academy.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general of the United States Marine-Hospital Service for the week ending March 18, 1899:

Small-pox—United States.

Mobile, Ala.....	Mar. 10.....	4 cases.	
Los Angeles, Cal.....	Feb. 25—Mar. 4.....	9 " "	2 deaths.
Washington, D. C.....	Feb. 25—Mar. 4.....	10 " "	
Washington, D. C.....	Mar. 4—11.....	11 " "	
Jacksonville, Fla.....	Feb. 18—25.....	2 " "	
Savannah, Ga.....	Mar. 8.....	7 " "	
One among troops returned from Arecibo.			
Louisville, Ky.....	Mar. 3—11.....	53 cases,	1 death.

Constantinople, Turkey.....	Feb. 20—27.....	16 " "	

Yellow Fever.

Rio de Janeiro, Brazil.....	Feb. 20—27.....	47 cases,	28 deaths.
Barranquilla, Colombia.....	Feb. 5—12.....	1 case.	1 death.
Barranquilla, Colombia.....	Feb. 12—18.....	1 " "	1 " "

Cholera.

Calcutta, India.....	Jan. 28—Feb. 4.....	12 deaths.
----------------------	---------------------	------------

Plague.

Calcutta, India.....	Jan. 28—Feb. 4.....	1 death.
----------------------	---------------------	----------

The Late Dr. William W. Van Arsdale.—At a special meeting of the medical board of Mount Sinai Hospital held March 18th, the following resolutions were adopted:

The medical board of Mount Sinai Hospital has learned with sorrow of the death of Dr. William W. Van Arsdale, which occurred at Atlantic City on March 17, 1899. Dr. Van Arsdale had endeared himself to all the members of the medical staff by the lovable traits of his character, and earned their respect by his eminent professional attainments and efficiency.

Resolved, That in the death of Dr. Van Arsdale the medical board has lost one of its most valuable and respected members, the institution a skillful surgeon and an able scientific worker; that the sympathy of the members of the medical board be extended to his family in their sad loss; and finally, that these resolutions be spread on the minutes and published in the *Medical Record*, *New York Medical Journal*, and *Medical News*.

Resolved, That a copy of these minutes be sent to his family.

[Signed.] ARPAD G. GEESTER, M. D.,
WILLIAM F. FLUHRER, M. D.,
Committee.

The Buffalo Academy of Medicine.—At the quarterly meeting, on Tuesday evening, the 21st inst., Dr. H. R. Gaylord read a paper on Tuberculous Infections in the Walls of the Blood-vessels and the Production of Miliary Tuberculosis, and the nomination of officers for the ensuing year occurred.

Surgeon-General Shoemaker, of Pennsylvania.—We learn from the *Medical Bulletin* that on February 7th the students of the Medico-chirurgical College, of Philadelphia, presented a sword to Dr. John V. Shoemaker, one of their professors and the new surgeon-general of the Pennsylvania National Guard.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 18th inst., Dr. M. A. Goldstein read a paper on The New Therapeutics of the Tympanic Cavity, and a discussion was opened on the papers presented by Dr. Carson, Dr. Mudd, and Dr. Bremer on The Surgery of the Gasserian Ganglion.

Two Cases of Whooping-cough treated by Aural Medication.—In the *Indian Medical Record* for February 15th Dr. S. Glanville Morris records the following

two cases treated according to the method recently advanced by Dr. G. A. Stephens in the columns of the *Lancet*, December 3, 1898:

Case I.—The patient was a boy, aged five years. He had been suffering from whooping-cough for one week. There was a discharge from both ears, very considerable from the left one. The face was puffy. He vomited with the cough and passed very bad nights. Dr. Morris syringed his ears with warm boric lotion and painted the meatus and membrana tympani in accordance with Dr. Arbour Stephen's method. The first night of the treatment the child slept well, the vomiting ceased, and the child has not whooped since. Pharyngitis, however, was still present, which caused the cough, but on the fourth day the pharyngitis had improved and the cough ceased. By the fifth day the child appeared to be well.

Case II.—The patient was a boy, aged six years. He had suffered from whooping-cough for one week. The appetite was poor; there was vomiting with the cough, but no pain or discharge from the ears. The ears were syringed and painted. On the next day there was no improvement. The treatment was continued. On the third night the child slept much better and whooped less, while the appetite improved. By the fifth day the child was well.

Medical Ethics.—Dr. Robert Roxburgh (*Bristol Medical and Chirurgical Journal*, December, 1898), in a presidential address delivered before the Bristol Medical-chirurgical Society on Progress and Practice, says:

"Now, it is as practitioners of the art of healing, as apart from its abstract and scientific aspects, that the commercial element first enters into our lives. Though it is the glory of medicine that its primary object is not money-getting, but the benefit of humanity, yet we are all agreed that the laborer is worthy of his hire, and so far from ignoring his fees every sensible man will see their fitness and insist on their payment. Unfortunately, however, it is from this side that breaches of ethical rule are apt to occur. The man who spends his days in a laboratory has few temptations to personal aggrandizement, but he whose income depends on the number of his patients is in a different position. Let me here, in the seat of a great medical school, assert that the principles of medical ethics are not taught to senior students as they should be, and students leave their school often without ever having heard the subject mentioned. It is frequently said that medical ethics are comprised in the saying: 'Do to others as you would be done by'; but that is not strictly true, for the honor of the profession as a whole, and not merely our individual advantage, is concerned in the maintenance of a high ethical standard, and perfectly upright men may make grave mistakes of etiquette without a suspicion that they are compromising principle. I have known a highly-touted young practitioner accept the post of medical officer to a notorious medical aid association, and who, the moment its true character was pointed out to him, resigned his office. I have known a man fresh from laboratory work abroad, acting on the advice of his friends, advertise in a newspaper the fact that he had purchased a certain practice, totally unconscious meanwhile that he was committing an unprofessional act. Many other instances might be named where ignorance and inexperience have had very unpleasant consequences—strained relationships, perhaps, or open rupture, between doctors practising in the same vicinity, and who

ought to have been on the friendliest terms. Of course, there are other cases where unscrupulous men, or men without gentlemanly instincts, consciously and willfully advertise themselves, or push their practice in underhand ways. For such the penalty must be isolation from the medical brotherhood of a district."

Osteomalacia cured by Chloroform.—Arcangela (*Gazzetta medica lombarda*, November 29, 1897; *Gli Incurabili*, November, 1898) records the case of a woman affected with osteomalacia for two years who kept habitually the dorsal decubitus and was unable to move herself in bed without aid. The patient, being under chloroform for half an hour, in which time she took thirty grammes, was able the same evening to separate the thighs a little. A month and a half later the pains ceased spontaneously. At the first menstruation, which occurred after twenty days of this treatment, the pains in the legs and thighs reappeared, disappearing immediately after the menstruation. The amelioration was continuous in spite of the recurrence of menstruation. The patient was then put also upon phosphorized oil, whence it may be held doubtful whether the great benefit of which the author speaks was due to the chloroform, the oil, or both.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 11 to March 18, 1899:*

FAUNTLEROY, POWELL C., First Lieutenant and Assistant Surgeon, will report to the commanding officer, General Hospital, Savannah, Georgia, for duty.

WOODSON, ROBERT S., Captain and Assistant Surgeon, is relieved from further duty in the Department of Santiago, and will proceed to Fort Clark, Texas, and report to the commanding officer of that post for duty.

A board of medical officers is appointed to meet in Washington for the purpose of making recommendations relating to a revision of the Standard Supply Table and Field Supply Table, as published in the *Manual for the Medical Department*, approved June 17, 1898. Detail for the board: CARTER, EDWARD C., Major and Surgeon; HALL, WILLIAM R., Major and Surgeon; LA GARDE, LOUIS A., Major and Surgeon; and MCNEX, EDWARD L., Captain and Assistant Surgeon.

By direction of the President, the following officers are honorably discharged from the volunteer army of the United States, to take effect this year: GUARD, ALFRED C., Lieutenant-Colonel and Chief Surgeon; KEAN, JETERSON R., Lieutenant-Colonel and Chief Surgeon; O'BRIEN, ROBERT M., Lieutenant-Colonel and Chief Surgeon; WILCOX, TIMOTHY E., Lieutenant-Colonel and Chief Surgeon; BIRMINGHAM, HENRY P., Major and Brigade Surgeon; BENN, GEORGE B., Major and Brigade Surgeon; BRYANT, WILLIAM S., Major and Brigade Surgeon; BURNS, ROBERT, Major and Brigade Surgeon; CHESNIN, PAUL, Major and Brigade Surgeon; D. NEWMAN, WILLIAM F., Major and Brigade Surgeon; FORD, FRANCIS C., Major and Brigade Surgeon; GLENNAN, JAMES D., Major and Brigade Surgeon; HED, EMER P., Major and Brigade Surgeon; JARVIS, NATHAN S., Major and Brigade Surgeon; MACMURRIN, JOHN L., Major and Brigade Surgeon; McDILL, JOHN R., Major and Brigade Surgeon; McMAHON, PETER D., Major and Brigade Surgeon; SHAKERS

SPEAR, EDWARD O., Major and Brigade Surgeon; and STEPHENSON, WILLIAM, Major and Brigade Surgeon.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending March 18, 1899:*

AYERHILL, H. D., Assistant Surgeon. Detached from the *Itawa* and ordered home.

BELL, W. H., Assistant Surgeon. Detached from the Naval Hospital, Washington, and ordered to the *Vixen*.

KINDLEBERGER, D., Medical Director, retired. Granted leave of absence to go abroad, from April 15th.

MCCLANAHAN, R. K., Assistant Surgeon. Detached from the *Richmond* and ordered to the Naval Hospital, Philadelphia.

ULSH, W. H., Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to the *Glacier*, April 6th.

Births, Marriages, and Deaths.

Born.

FOSTER.—In New York, on Sunday, March 12th, to Dr. and Mrs. Matthias Lanckton Foster, a daughter.

Married.

SIMPSON—THOMAS.—In New York, on Tuesday, March 14th, Dr. William Payne Simpson and Miss Lucy Alsop Thomas.

Died.

IVY.—In West Point, Mississippi, on Friday, March 17th, Mrs. G. Ivy, wife of Dr. Thomas G. Ivy.

PARKER.—In Gloucester, Massachusetts, on Thursday, March 16th, Dr. J. Howard Parker, of Boston, aged thirty-two years.

SEABURY.—In Yonkers, N. Y., on Thursday, March 16th, Dr. John H. Seabury.

VAN ARSDALE.—In Atlantic City, N. J., on Friday, March 17th, Dr. William W. Van Arsdale, of New York, in the forty-fourth year of his age.

WATERMAN.—In New York, on Wednesday, March 15th, Dr. Sigismund Waterman, in the eighty-first year of his age.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

XL

RIGHTS AND LIABILITIES OF THIRD PARTIES.

(Continued from page 387.)

Liability of Party asking Physician to attend Another.—Whether or not the mere request by a third party for a physician to call upon a particular patient, without stating that he acts as agent for such patient, will render the third party liable to the physician for services rendered the particular patient is a question

upon which there is some conflict, the courts in the State of New York holding the third party liable in such cases, while those of other States in which the question has arisen renounce the doctrine of liability under such circumstances.

An extreme case of the sort arose in New York city in 1873. A person called at the office of a physician. The physician being absent, he wrote upon his business card, "Call on Mrs. —, at No. — Broadway," and left it with the clerk, with the request to hand it to the physician and tell him to come as soon as possible.

The jury rendered a verdict for the physician, and the court to which the case was appealed refused to disturb the verdict. The court, in the opinion, said: "There was nothing on the card to indicate to the plaintiff, before he rendered the services, that the defendant had called at his office at Mrs. —'s request, and that he was therefore only acting as her messenger."

"The defendant might very readily have secured himself from all liability by simply writing the memorandum on a blank card, or by adding to what he wrote on his own card something that would have apprised the plaintiff of the fact that he acted in the transaction for Mrs. — as her agent. . . . Having neglected to do this, the plaintiff was, under the circumstances, justified in believing that he was employed and would be paid by the defendant."*

Later, in 1896, the supreme court refused to disturb the verdict of the jury fixing the liability upon a son who summoned a doctor to attend his father by the following words: "Doctor, I want you to come and attend my father. He had a doctor who was not satisfactory." In the opinion the court cited the case of *Bradley vs. Dodge* with evident approval.† These cases represent an extreme view, and, as the question has never been passed upon by the court of last resort in the State of New York, it is impossible to say what that tribunal will determine the law to be.

The better rule of law, it is thought, and probably the one which would be followed in any State except New York, is that the mere calling for a physician, or requesting him to call upon a certain patient, will not make one liable to such physician for his fees in the particular service. This is shown by these cases:

The superintendent of a coöperation company sent a messenger to a physician summoning him to the works of the company to attend an injured employee. The court of appeals for Missouri, in considering the matter, said: "We take it that the law will not imply, upon this evidence, a contract either on the part of the corporation or on the part of Mr. — (the superintendent) to pay for these services. The general rule, no doubt, is that, where a person requests the performance of a service, and the request is complied with and the service performed, the law raises an implied promise to pay the reasonable value of the services. But this implication does not obtain where one person requests a physician to perform services for a patient, unless the relation of the person making the request to the patient is such as to raise a legal obligation on his part to call in the physician and pay for the services. Where a husband calls in a physician to attend upon his wife, or where a father calls in a physician to attend upon his minor child, the law implies a promise on his part to pay the reasonable value of the services, because there is a legal

* *Bradley vs. Dodge*, 45 How. Pr., 57.

† *Foster vs. Meeks*, 18 Misc., 164; 41 N. Y. Supp., 950.

obligation on his part, in either case, to furnish necessities for the patient's benefit. But no such implication arises where one calls in a physician to attend upon a stranger, or upon one to whom he is under no legal obligations." Quoting further in the same case, the court said: "The reason and policy of this rule are obvious, especially in cases like the present. When a person is dangerously wounded, and perhaps unable to speak for himself, or suffering so much that he does not know how to do it, any person will run to the nearest surgeon in the performance of an ordinary office of humanity. If it were the law that the person so going for the surgeon thereby undertakes to become personally responsible for the surgeon's bill, and especially for the surgeon's bill through the long subsequent course of treatment, many would hesitate to perform this office, and in the meantime the sufferer might die for the want of necessary immediate attention." *

A case stronger than the one above given is reported in Vermont. A brother who had been acquainted with a physician took him to see his insane brother and earnestly requested him to undertake the treatment of the insane patient. There was no express agreement as to the payment for the services. The court, in considering this case, said: "It appears that all of the services were performed for the brother of the defendant, who, though insane, was liable therefor. The services were not beneficial to the present defendant, and he was under no legal obligation to pay for them unless as an express undertaking, or unless it may fairly be inferred from the evidence that it was the intention of both parties that the plaintiff should perform the services and the defendant should pay therefor." †

In the case of Rankin vs. Beale, a father sent for a physician to attend his adult son at the father's house, and after the services were rendered agreed with the physician to pay for them. The court held that the father was not bound by merely sending for the physician to pay his fee, and the promise of payment being made after the services were rendered was without consideration and void. ‡

A third party, acting as messenger, was sent for a certain physician to assist in the performance of an operation. Not finding him in, he went to the office of another physician and said: "I have come after you to go and see a sick man." The third party went part way with the physician to the patient's house, when, meeting with another person going to see the patient, he separated from the physician. Upon arriving at the patient's house, the doctor who was in attendance on the sick man explained to him what had occurred, and said that the physician who had just arrived would assist in the operation, which was assented to, and the operation was performed. The court said: "The evidence tended to show that the plaintiff (the physician) was aware of the fact that the defendant acted merely as a messenger, and did not intend, or expect, to make himself personally liable for the services which were to be rendered to the sick man. If, upon the explanation made by the doctor in attendance, the plaintiff was not willing to assist at the instance and on the credit of the sick man, it was his duty then to make known his objections.

"To hold the defendant liable under these circum-

stances would deter every one from doing the charitable office of going after a doctor for a sick neighbor." *

A physician attending a patient who was injured and lying at his son-in-law's house proposed on several occasions to discontinue his services, when he was requested not to do so by the son-in-law. After the patient's death the physician presented his bill, amounting to five hundred dollars, to the son-in-law, as a claim against him personally, and asked its payment. He did not deny his responsibility, but objected to the amount; and after a dispute and some angry words he wrote an order upon an attorney for two hundred dollars to be paid out of a certain claim when collected, and handed it to the physician, saying he would give him that, and would not pay him another cent, and if he did not take that he would not get anything. The account was charged upon the physician's books to the patient, and when the bill was presented to the son-in-law he was the patient's administrator; but that was unknown to the physician. The court said: "Though the physician in the beginning, may have rendered services solely upon the patient's responsibility, in the absence of a special contract he was not bound to continue to do so, and had the right to discontinue, and enter into a contract with the son-in-law to become responsible for his subsequent services; but, in such case, the burden is on him to show, not only a discontinuance, or a proposal to discontinue, but also an agreement on the part of the son-in-law to be responsible. There is no pretense of an express agreement; in the absence of such, it was necessary for the physician, in order to entitle him to the affirmative charge, to prove facts undisputed, from which the law would conclude an actual, though implied, agreement. The cause of the physician's proposal to discontinue his attendance does not appear. . . . Every person who may go for the regular attending physician when needed by his patient, or who, from considerations of friendship or humanity, may request him not to discontinue his attendance, does not render himself responsible for the services of the physician. Whether he does or not, depends upon the attendant circumstances." †

In the following cases circumstances have been shown which were considered equivalent to a direct contract or undertaking to pay the indebtedness.

In the case of Clark and Meigs vs. Waterman, a physician was called by the defendant to attend a girl who had lived with him from the time she was eight until she was eighteen years of age, and who had spent nearly seven eighths of her time subsequent thereto, up to the time of her sickness and death, in his household. The defendant manifested much interest in the case, was dissatisfied with the services of the first physician employed, discharged him, and employed another physician to attend the patient; he called for the bills of the physicians to lay before the town, "to see if they would not assist him." These facts were considered sufficient to show that the defendant intended and gave the plaintiffs to understand that he was himself the employer, and he was accordingly liable.

The employee of a lumber company was injured, not while in the course of his employment, but in a private brawl. The secretary, treasurer, and general business manager of the company sent a telegram to a physician as follows:

* Meisenbach vs. The Southern Cooperage Co., 45 Mo. App., 322.

† Smith vs. Watson, 11 Vt., 332.

‡ Rankin vs. Beale, 68 Mo. App., 325.

* Smith vs. Reddock, 56 Me. Law N. C., 14.

† Curry vs. Shelby, 99 Ark., 171, 18 S. Rep. 90.

‡ Clark and Meigs vs. Waterman, 7 Ark., 76.

"To Dr. —: Come here immediately by quickest means; man shot in breast.

[Signed.] " — Lumber Company."

The doctor responded, and continued his visits for six weeks. The bill was presented to the company, but they denied liability and refused to pay. The secretary-treasurer and manager denied his liability, but offered, by way of compromise, to pay ten dollars, the price of the first visit. The offer was refused, and suit brought against the company and the officer who sent the telegram. It will be observed that the telegram by which the physician was summoned was not a request for him to attend any particular person, but an order for him to report to the company direct. So far as the reported case shows, the sufficiency of this order to bind them, had it been properly authorized, does not seem to have been questioned; but the company contested the claim on the ground that the officer sending the telegram had no authority, express or implied, to bind it to pay for such services. The officer's excuse for using the company's name was that he was personally unknown to the physician, and was afraid the physician would not come unless summoned in the company's name. The trial court found that the company was not liable, but the secretary was personally liable. The principle upon which the secretary was held liable is that if the agent exceeds his authority, so that his principal is not bound, he will himself be liable for the damages thus occasioned to the other contracting party, although he may have been innocent of any intention to defraud.*

A landlord sent orders to a physician requesting him to call upon his tenants. The physician understood from the orders that the landlord intended to pay, and accordingly charged the services to him and made no efforts to collect from the tenants. The landlord testified that he did not consider that the orders made him personally responsible; afterward, however, he offered the physician some fodder to apply on the account, and also promised to make a payment of money at a stated time. The trial justice gave judgment against the landlord for the full amount of the claim, and the appellate court refused to disturb the judgment, as there seemed to be evidence to support such a judgment.†

The question whether or not an implied promise by a third person to pay exists in a particular case is nearly always one of fact, to be determined by the jury, whose duty it is to consider all of the attendant circumstances and carefully weigh the evidence of the parties, plaintiff and defendant, and, when such evidence is conflicting, to consider the character and reputation for truth and veracity of the witnesses, their intelligence and opportunity for knowing the real truth, and all other matters which bear upon the question at issue.

Liability of Corporation for Employment by Agent.

—A prolific source of litigation is the question of whether or not the employment of a physician by an agent or officer to attend an injured employee binds the corporation or company whom he represents to pay the physician's fee.

This question arises more frequently in connection with railroad companies than with all other concerns, the character of the employees' duties being such that they are liable to become seriously injured at almost any time and at any point on the line of the employer. When such accidents occur the services of a physician

are needed at once, and it is usual for an employee having the highest authority in the immediate locality, usually the station agent or conductor, to summon and employ for the company the nearest competent physician and surgeon. The railroad companies, instead of meeting such obligations promptly, have manifested a preference to avoid paying for the services rendered in such cases when the circumstances of hiring are not such as legally to bind them to pay. A careful examination, therefore, of what will and what will not amount to a binding obligation on the part of the company will be of material value.

General Rule of Liability.—It may be stated as a general rule that a company or corporation is under no legal obligation to provide medical attendance for persons injured in its service; and if a physician or surgeon seeks to recover from a company for attendance upon an employee so injured, he must show that he was employed to render such services by a servant or officer of the company having authority to employ him; or, if the person employing him did not have authority so to do, he must show a subsequent ratification by those having authority to act for the company in such capacity.*

Letters to the Editor.

SOME DRUG-STORE ABUSES.

128 EAST FIFTY-SEVENTH STREET, March 13, 1899.

To the Editor of the New York Medical Journal:

SIR: The modern American drug store, called by courtesy a pharmacy, is a hybrid thing, partly professional and partly mercantile. To this fact are due many of its shortcomings. The sale of miscellaneous merchandise seems, in the majority of cases, the most serious and important purpose in view, and the spirit which dominates its conduct is chiefly commercial. It is found to be, unfortunately, the fact that the percentage of profit which a drug or preparation will yield is of more importance in determining its selection than the degree of its therapeutic efficiency. An employee is held in estimation more on account of his proficiency as a salesman than because of his knowledge of medicines or his skill in their preparation.

These are wholly natural and direct consequences of the commercial domination of the calling, and in turn become causes of the further impairment of its efficiency in its legitimate sphere.

The primary purpose of the occupation seems to be largely lost sight of. The business of preparing and dispensing medicines should be an accessory to the work of the physician. The modern city drug store is more a combination of bazaar and bureau of general information.

An outgrowth of the same commercial spirit is the persistent pushing of "our own," or home-made, nostrums in place of the widely advertised articles of this class. This is a practice which is rapidly becoming general, since the competition of the department stores has abolished the profit on the popular "patents."

* Toledo, Wabash, and Western Ry. Co. vs. Prince, 50 Ill., 26. This rule is probably changed in South Carolina by a statute which imposes upon the railroad company the duty of giving notice to the most accessible physician of all accidents which occur on its road. Rev. Statutes of South Carolina, § 1690.

* Dale and Banks vs. Donaldson Lumber Co., 18 Ark., 188.

† Speer vs. Meschino, 16 S. C., 505; 24 S. E. Rep., 329.

The general sale of these ready-made medicines is bad enough, but the blind pushing of the home-made nostrum is infinitely worse. They are ill made as a rule, and are sold regardless of their appropriateness to any given case. It is a rule to pay the salesman according to the number of bottles of the "our owns" he can sell, and he can scarcely be expected to be too scrupulous in his statements under the circumstances. The customer suffers first and most severely from this system, but the doctor is discredited by interested and reckless statements, and the reputable pharmacist will in time suffer from its reflected perniciousness.

In the exercise of his legitimate functions, in the preparation and sale of medicines and allied articles, the druggist also sins against the physician and the public. The indiscriminate and unauthorized renewal of prescriptions is an almost universal practice. The physician is perhaps primarily to blame for this, but the evil is none the less in need of correction.

Prescriptions are renewed without regard to fitness, age, date, or previous ownership. The nature of the drug dispensed is not seriously considered unless in exceptional instances, and the larger share of the cases of habitual use of morphine, cocaine, and other enslaving drugs is due to this unregulated practice.

I recall a case where a prescription containing cocaine and calling for four ounces had been filled for over seven years without the physician's authorization, and it had so grown in quantity that fifteen pint bottles were sent out at a time, and this quantity at frequent intervals. I have examined morphine prescriptions filled for fifteen years and obtained without restriction, either by the original owner or by any one who represented himself as from this person. Nearly all stores are equally guilty in this regard.

The greatest and most crying evil is one closely akin to this. This is the unconsidered sale of poisons, and of the drugs which enslave. This latter feature is the worst in effect and is the most common. The laws affecting the sale of poisonous substances are insufficient at best, and are difficult to enforce. Except in those cases where the will to conform to them is present and actuates their enforcement, they are practically dead letters. Not only is it easy for any person to obtain nearly any poison on the list, but there are a number of stores in certain parts of the city—pariahs among their kind, be it said to the credit of the rest—whose revenues chiefly accrue from the sale of enslaving drugs. A considerable element among their patrons is the class who make use of "knock-out drops" and preparations employed for similar purposes. Business is most brisk in these places when the day is done and it is near the closing hour at other stores. Then the pitiful parade of the unfortunates begins.

The painted and diamond-locked courtesan comes for her nightly portion of cocaine. She knows she is gayer, her eyes are brighter after it, and she has found how shaking and almost collapsed she becomes if anything prevents her coming, for she is like the rest of her kind, and "sufficient for the day" is her motto. The wrinkled and bent old hag with a parchment skin, blackened teeth, and dark-stained lips presents a begrimed box with ten cents or perhaps a quarter, and without a word. The two would know she wanted opium. A dozen tiny pills are given to the next applicant. She does not state her demands in words, it is not necessary. The clerk knows she wants morphine pills, and nothing less than half grain, the strongest

made, will do for her. Perhaps she takes half of them when she pauses on her way to the door. Next, when midnight draws nigh, the dreamy-eyed, emaciated throng of "dope fiends" begins to arrive, and if the store is open all night this contingent drags in from time to time until daylight. All this I have seen, and more. I have been told that there are some places where the very poor of these creatures go, and where they hold an outstretched hand for the five cents' worth of morphine and lick up the little square of white crystals from a dirty palm while they wait. I know that there are a number of stores where the opium prepared for smoking is sold, though not all who sell the other forms of the drug will handle the "dope."

In these same stores the sale of abortifacients is an important item, and they are also the distributing points for the many specifics for "lost manhood," and all that class of schemes for duping the simple-minded.

I call attention to these abuses in this way because I do not believe that the members of the medical profession, as a rule, are aware of the extent to which they exist, and, knowing myself of the depth of the evil, think something should be done toward its amelioration. From the medical profession should come the first move in the matter.

ROBERT C. BICKELL, M. D.

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of December 7, 1898.

The President, Dr. S. ALEXANDER, in the Chair.

Case of Abdominal Tumor.—Dr. W. J. PULLEY presented a patient with abdominal tumor who had been exhibited before the society last winter. At that time there had been an abdominal tumor in the right hypochondriac region. This tumor had seemed to be so intimately connected with the liver that he had supposed it to be a growth of the liver, or a cyst of the gall bladder due to obstruction of the common duct. Previous to coming under observation, three years ago, while lifting a very heavy wagon, he had experienced severe pain in the right lumbar region. About one week later he had felt an enlargement in the right side. When seen by the speaker shortly afterward, he was very anæmic, and there was a tumor under the free border of the ribs which was moderately movable. It was not associated with fever or pain. The tumor did not seem to be connected with the kidney. Under tonic treatment the patient had rapidly improved, and had returned to the country. On October 1, 1898, he had again come under observation, and the tumor at that time had been very much larger than before. The patient had then been operated upon by Dr. Joseph D. Bryant, and a simple cyst, connected with the right kidney, found. Most of the kidney found in a healthy condition, the organ had been left in situ.

Dr. JOSEPH D. BRYANT said that at the time the patient had been previously presented to the society there had been considerable doubt as to the situation and nature of the tumor. The patient had come under his care on October 5th. The tumor was to the right of the

median line, and extended firmly under the ribs down to the anterior superior spinous process. He had been seen at that time by many of the visiting surgeons and physicians of the hospital, who had declared the tumor to be one connected with the kidney. He had then made an incision, about five inches in length, purposely through the left rectus muscle to inspect the tumor. The incision having been extended until its upper limit was at the free border of the ribs, he had endeavored to remove the growth. In removing such a tumor connected with the kidney, the question came up as to the removal of the tumor at the outer side of the descending colon by carrying the colon across to the median line, thereby saving the vessels and obviating the danger of sloughing, or of opening directly downward upon it, and in that way endangering, to a certain degree, the vessels supplying the colon. Scrutiny of the anterior surface disclosed the fact that the pressure which had existed for a long time had been such as to destroy the vascular channels crossing it. An incision had therefore been made through the peritoneum over the tumor, and an attempt made to pull it off. That had been found impossible to do except at the periphery. The tumor was firmly pressed against the right side of the abdominal wall, and extended across a considerable distance to the left of the vertebral column. The tumor had then been tapped with a trocar, and three quarts of fluid evacuated. It had then been easy to raise a portion of the sac up through the incision. While doing this, it had been noticed that the kidney appeared to be normal, both as to size and general physical appearance. It was deemed wiser to attach the sac to the opening, and this had accordingly been done. After the sac had been drawn up, and before it had been stitched to the opening, a considerable portion of the sac had been cut away from the top. Through this opening the finger could be passed down to the bottom. The base was made up of the anterior surface of the kidney and of the sac. A large number of complete layers of lymph were washed out, the sac stitched to the wound, and counter drainage carried through the flank. The object of this drainage was to allow an easy exit for the pus if inflammation should ensue. The patient had made a comparatively smooth recovery. When he left the hospital there was a sinus, and this still existed, although it was quite superficial. The patient's general condition was markedly improved. Dr. Harlow Brooks had reported that no form of anatomical elements, with the exception of leucocytes, had been found in the cyst fluid. The fluid had been stained for bacteria, but none had been found. The membrane lining the cyst was composed of lime salts and disintegrated fibrin.

Dr. J. W. S. GORLEY remarked that there seemed to be fluid still present, as indicated by an obscure sense of fluctuation, obtained by bimanual palpation.

Prostatectomy.—The PRESIDENT presented a fresh specimen of a prostate that had been removed that day by prostatectomy. The patient was about sixty-two years of age, and he had had for five years marked symptoms of prostatic obstruction. He had begun catheter life three years ago, and had been entirely dependent upon the catheter during the past year. During this time, the speaker said, he had operated upon him twice by litholapaxy for recurring phos-phatic vesical calculi. The first operation had been done under a general anesthetic, and the second under cocaine, the interval being five months. This last operation had

been done two months ago. Since then there had been evidence of spasm at each urination, which occurred every two hours. Before the first stone operation had been done prostatectomy had been advised, but the patient, who was a physician, had declined to submit to it. This morning the two large lateral lobes and a smaller one occupying the position of the middle isthmus had been removed. There were also several smaller fragments. All had been removed by sub-mucous enucleation. He hoped to be able to show the ultimate result.

(To be concluded.)

Book Notices.

The Practice of Obstetrics. By American Authors. Edited by CHARLES JEWETT, M. D., Professor of Obstetrics and Diseases of Children in the Long Island College Hospital. Illustrated with Four Hundred and Forty-one Engravings, Thirty-four of which are in Colors, and Twenty-two Colored Plates. New York and Philadelphia: Lea Brothers & Co., 1899. Pp. xiii-17 to 768. [Price, \$5.]

It is not an easy task to prepare a variorum book of no larger bulk than this that will fulfill the editor's aim, that of furnishing "a clear and practical treatise suited to the needs of medical classes" and "a concise and comprehensive guide for the practitioner." It seems to us, however, that Dr. Jewett has succeeded very well in the undertaking.

The chapter devoted to the changes wrought in the maternal organism by pregnancy might perhaps have been amplified to advantage. On the other hand, an unusual amount of space is devoted to the care of the newborn child, and the advice given is very judicious.

Manual of Ophthalmic Surgery and Medicine. By WALTER H. JESSOR, M. A., M. B. Cantab., F. R. C. S. Eng., Ophthalmic Surgeon to and Lecturer on Ophthalmic Medicine and Surgery at St. Bartholomew's Hospital, etc. London: J. & A. Churchill, 1898. Pp. xiv-169. [Price, \$3.]

THIS is a tolerably systematic, practical, and concise manual, intended for students, and better adapted for the English than the American student. It contains twenty-three chapters and an appendix. The few illustrations in black are good, but the chromolithographs are defective in coloring. It seems almost impossible in a student's manual to give a good chapter on the errors of refraction and accommodation, and this book is no exception to the rule. On the other hand, the chapter on muscular anomalies is a really good one, and very clear. For the student in this country there are, however, better text-books.

A Syllabus of Materia Medica. Compiled by WARREN COLEMAN, M. D., Instructor in Clinical Medicine and Materia Medica in Cornell University, Medical Department, etc. New York: William Wood & Co., 1899. Pp. vi-169. [Price, \$1.]

THIS is an excellent little guide to the more important drugs used in medicine, with the doses and therapeutic actions arranged under each drug. There are

also useful tables of the alkaloids, the official preparations, etc.

Atlas of External Diseases of the Eye. By A. MALT-
LAND RAMSAY, M. D., Ophthalmic Surgeon, Glasgow
Royal Infirmary, etc. With Thirty Full-page Colored
Plates and Eighteen Full-page Photogravures.
Glasgow: James MacLehose and Sons. New York:
The Macmillan Company, 1898. Pp. xvi-195.
[Price, \$20.]

This is a magnificent specimen of the bookmaker's
art. It is a folio volume of nearly two hundred pages.

The illustrations are supplemented by the text,
which gives detailed descriptions of the various diseases
in their different phases. This text is a model both of
conciseness and of comprehensiveness. The various dis-
eases are considered in their aetiology, symptomatology,
and pathology with a fullness and care that are most
admirable. The illustrations are the most perfect of
their kind that have yet been published. The plates
have been executed from photographs of actual cases met
with at the author's clinic at the Glasgow Eye Infirmary.
The whole book is the most perfect type of what is best
in text and illustrations, and the author's work is admi-
rably supplemented by the publisher's art.

BOOKS, ETC., RECEIVED.

*General Physiology: An Outline of the Science of
Life.* By Max Verworm, M. D., Ph. D., A. O. Professor
of Physiology in the Medical Faculty of the University
of Jena. Translated from the Second German Edition
and edited by Frederic S. Lee, Ph. D., Adjunct Pro-
fessor of Physiology in Columbia University. With
Two Hundred and Eighty-five Illustrations. New
York: The Macmillan Company, 1899. Pp. xvi-615.
[Price, \$4.]

*An American Text-book of Diseases of the Eye, Ear,
Nose, and Throat.* Edited by G. E. de Schweinitz,
A. M., M. D., Professor of Ophthalmology in the Jefferson
Medical College, Philadelphia, etc.; and B. Alexander
Randall, M. A., M. D., Ph. D., Clinical Professor of
Diseases of the Ear in the University of Pennsylvania,
etc. Illustrated with Seven Hundred and Sixty-six En-
gravings, Fifty-nine of them in Colors. Philadelphia:
W. B. Saunders, 1899. Pp. 3 to 1251. [Price, \$5.]

Elementary Physiology. By Benjamin Moore,
M. A., Professor of Physiology in the Medical Depart-
ment of Yale University, etc. With One Hundred and
Twenty-five Illustrations. New York, London, and
Bombay: Longmans, Green, & Co., 1899. Pp. vi-295.

Addresses and Papers. By the Members of the In-
structing Staff of the New York State Veterinary Col-
lege. For the Years 1896-1898.

*Fifth Annual Report of the State Charities Aid As-
sociation to the State Commission in Lunacy.*

*Thirty-first Yearbook (October 1, 1897-October 1,
1898) of the New York Orthopaedic Dispensary and
Hospital.*

*Thirty-third Annual Report of the St. Francis Hos-
pital, New York.* For the Year ending December 31,
1898.

*Twenty-first Annual Report of the Prince of
George's Eye, Ear, and Throat Charity Hospital of Baltimore.*
1898.

*Notes on the Absorption versus the Excretion of
Milk.* By E. DUNCAN BULLOCK, M. D. [Reprinted from
the *Journal of the American Medical Association*.]

Miscellany.

Amnesia after Excitement.—Féré (*Belgique médi-
cale*, July 7, 1898; *University Medical Magazine*,
March) states that amnesia and other disturbances of
memory may supervene in persons ill with disturbances
of the nervous system or in those hereditarily predis-
posed, after injuries, excessive exertion, and even after
coitus; and that they may also follow pure psychic
disturbances either immediately or after the patient has
been exposed to them for some time. He reports the
case of a woman, who had never been ill with any nerv-
ous affection, and who resided with a sister whom she
loved very much. The latter became ill, and was nursed
by the other with great diligence and care. The sister,
however, died. The other remained apparently normal,
until the corpse was being removed from the house,
when she suddenly lost all recollection of her sister.
She remained in this condition several weeks, at the
end of which time the recollection returned suddenly in
a dream.

Diabetes Mellitus in a Ten-year-old Girl.—Haus-
halter (*Annales de médecine et chirurgie infantiles*, No.
13, 1898; *University Medical Magazine*, March) reports
a most unusual case of diabetes in a young girl aged ten
years. The glycosuria amounted on an average to about
a hundred and twenty-two grammes of sugar a day,
during an irregular observation of seven months. Poly-
uria was not excessive. The subjective manifestations
consisted of thirst and polyphagia, which were not
marked. Various abscesses developed on the lower ex-
tremities, the disease progressed, the child became mar-
rantic, and died at the end of about two years, despite
all treatment.

**Treatment of Chronic Metritis with Chloride of
Zinc.**—Delbet (*Annales de gynécologie et d'obstétrique*,
January; *Indépendance médicale*, March 1st) says that
intra-uterine injections of chloride of zinc appear to be
equally efficacious in chronic metritis with curettage,
and possess, moreover, two appreciable advantages:
they do not risk aggravation of lesions of the annexa;
and, secondly, they do not call for anaesthesia or lay
the patient up. Many patients rise immediately after
the injection, and even those who suffer somewhat can
get about their occupations after a few hours of repose.

**The Treatment of Suprapubic Vesical Fistula with-
out Operation.**—Dr. Charles Lester Leonard (*Thera-
peutic Gazette*, February 15th) records the following in-
teresting case:

Three months before the patient came under his
care she had been operated on for a pelvic abscess. By
some mischance the bladder had been opened and a su-
prapubic fistula had formed, through which both urine
and pus were discharged, while there had been a contin-
uous interference of infection between the abscess, the
bladder, and the surrounding pelvic soft parts.

The only treatment resorted to before
Dr. Leonard saw her had consisted in irrigation on the
known tendency of such a case to become chronic, the
but little had been accomplished, and a permanent fistula
had as a consequence the patient was in a most de-
plorable condition, with some suppuration and a most
serious and connective tissue infection from the protracted
of infection can be made to the patient's health.

condition of the patient and the extent of the infection, with the probability of renal involvement, made it seem desirable to defer operation until the patient's physical condition could be improved. She was therefore removed to a private hospital ward, where strict antisepsis could be maintained.

The first indication in the treatment was the prevention of any further interchange of infection between the bladder and abscess cavities. Suprapubic siphon drainage was secured for the bladder in the following manner: A fine rubber drainage tube was threaded upon a silk ligature attached to an eyed probe. After the probe had been passed through the sinus into the bladder, and while it was held by the attached ligature, the drainage tube was slipped over it into the bladder. A suitably connected tube conducted the urine into a receptacle beneath the bed. Drainage tubes were passed into the abscess cavity and sinuses in a similar manner. A wall of granulation tissue speedily formed between these various tubes and effectually prevented any further intercommunication.

The marked cystitis was treated by irrigating with hot boric-acid solutions, and as soon as inflammation of the external genitalia, which had resulted from the continual flow of pus over that region, had subsided, a catheter was passed and through-and-through irrigation was used daily. The urine was also sterilized and rendered acid by the administration of benzoic acid as employed by Emmet in the following formula:

B. Benzoic acid	2 drachms;
Boric acid	3 "
Distilled water	12 ounces.

M. S.: One tablespoonful well diluted three or four times daily.

The general pelvic tenderness was rapidly decreased by the external application of a fifty-per-cent. ichthylol ointment and the same drug was used in vaginal suppositories.

The greatest difficulty experienced was in the treatment of the abscess, as antiseptics had to be employed that would not irritate the bladder, while it was impossible to get good drainage. The complete emptying of the abscess cavity and thorough antisepsis were secured by the employment of the official boroglyceride, which, while acting as a non-irritant antiseptic, also, by its greater specific gravity caused the displacement and expulsion of all the pus. Although the progress toward recovery was at first slow, the combined local and constitutional treatment enabled the patient to make such progress that operation was again postponed.

As soon as the urine became normal and the sinuses ceased to discharge pus, the suprapubic drainage was removed and catheterization at regular intervals substituted. The drainage tubes in the sinus leading to the abscess cavity were not removed till the urinary fistula had healed. This occurred promptly after the removal of the siphon drainage. The sinuses leading to the abscess cavity were then allowed to heal; their healing, however, did not take place as rapidly.

In all the sinuses the first drainage tubes introduced were necessarily small, but each gradually dilated the sinus in which it lay, when a larger one was introduced in the manner described.

The continued good health of the patient (now over two years) and the knowledge of the condition probably produced by the numerous pelvic adhesions have deterred the author from further operative interference, which, unless new indications arise, seems hardly justifi-

able. The author says that the case is of interest as a demonstration of the relief that proper antiseptic measures can afford in cases where suppurative disease has so depressed the system and devitalized the tissues that operative interference is hazardous and inopportune. It also illustrates the fact that conservative antiseptic surgery, in certain instances, is capable of assisting Nature to accomplish cures where radical operation would certainly be attended by failure; and further, that asepsis or antisepsis is essential to the spontaneous closure of suprapubic vesical fistula.

Suprapubic Transplantation of the Penis.—Wagner (*Centralblatt für Chirurgie*, July 30, 1898; *American Journal of the Medical Sciences*, March, 1899) reports a case in which, as the result of trauma, so great a defect ensued in the posterior portion of the urethra that it was impossible to close it by the usual methods. There had been great loss of tissue, with a recto-vesical fistula as well as a perineal one, and the rectum had been so injured that it became necessary to do a formal resection of the lower portion for the resulting stricture.

The extensive scar tissue which resulted from these conditions made it impossible to obtain normal skin for a plastic operation. Mikulicz, who was the operator, therefore determined upon a new and radical measure. An incision was made from above the symphysis pubis down upon the dorsum of the penis, and reached the bone. The ligaments supporting the penis were detached, and with them the entire penis without injury to it. The peritoneum was displaced upward and the bladder wall exposed. A deep groove was cut in the symphysis pubis, which permitted the penis to lie in it. The urethra was then united to the bladder above the symphysis, and a catheter passed through into the bladder, where it was permitted to remain. The case followed a very satisfactory course. The union of the penis to the bladder was uncomplicated, while the urethra was kept dilated by the judicious employment of gradual dilatation by sounds. The urine was passed by the catheter, and the patient at the time of the report was able to retain the urine for two hours and then pass it in a stream. Sounds, however, had to be used regularly to keep the urethra from contracting. The perineal fistula decreased in size, but urine would dribble through it if it was retained over two hours. The result attained was far preferable to any that could have been secured by other means, and is one that can be employed wherever there has been an extensive destruction of the prostatic and membranous portions of the urethra.

A History of the Case Essential.—The *Doctor's Fac-lotum* for March and April quotes the following from *Puck*:

"A man must not only have a fractured skull but a clear and coherent explanation of how he came to get it before he is admitted to a New York hospital."

Ligature of the Common Carotid for Hæmorrhage from the Ear.—Dr. Stewart (*British Medical Journal*, February 18th), at a recent meeting of the Leeds and West Riding Medico-chirurgical Society, said that on May 18, 1898, he was called to a child suffering from hæmorrhage from the ear. On arrival he found a little girl, aged three years, lying on a sofa almost lifeless. Three weeks before she had got thoroughly wet, and a few days afterward a lump appeared at the angle of the left jaw, with pain on swallowing. On the fourteenth day from the appearance of the swelling in the neck, the child

complained of intense earache, and a few hours afterward there was a profuse discharge of foul, greenish pus from the left meatus. Forty-eight hours later an attack of hemorrhage from the ear occurred, followed by another on the same day, and two more on the day following. The bleeding always ended in faintness. Dr. Stewart saw the child on the third day from commencement of the hemorrhage, when she had another attack. He packed the external meatus with gauze, and banded the head up tightly, but, as the bleeding recurred during the night, the mother consented to an operation. The left common carotid was tied. The child was quite well within a week. The blood was distinctly venous in character. The only change noticeable after the operation, and one which still persisted, was a flushing of the right side of the face, with profuse sweating on exertion, as compared with pallor on the left side, on which the carotid was ligatured.

The Topical Use of Quinine in Leucorrhœa.—According to the *Medical Review of Reviews* for February, R. S. Miller, F. R. C. S. (*Lancet*, January 21st), confirms the observations of Dr. Hardwicke (*Review*, No. 4, p. 61). He has employed hydrochloride of quinine in all cases of leucorrhœa, granular erosion of the cervix, and in all forms of vaginitis and septic endometritis for eight or nine years. Its action is admirable, this salt of quinine being powerfully antiseptic and mildly astringent. As an intra-uterine douche in septic endometritis it is very prompt in effect and perfectly unirritating. For vaginal use he has employed pessaries of two grains or three grains of the hydrochloride in glyco-gelatin medium, one-drachm or two-drachm size, the glyco-gelatin being made with hazeline (ext. hamamelidis liq.) instead of with water. Such pessaries, especially the larger sizes, reduce uterine congestion, and cause a remarkable contraction in a flaccid vagina, so that after a few days of their regular introduction at bedtime it is sometimes necessary to employ a smaller speculum for examination. Hydrochloride of quinine is soluble 1 in 36 of water. For douching, a grain to the ounce of warm boric-acid solution answers well, as also for washing out the bladder. Four grains to the ounce with a little cocaine in boric solution makes a good urethral injection and may be used at the very earliest stage of gonorrhœa. From two to four grains to the ounce of the same salt in boric solution, with or without cocaine as required, is by far the best lotion for ophthalmia neonatorum and gonorrhœal ophthalmia, and also for ulcers following hypopyon.

The Perceptive Properties of the Hair.—Von Boehmer (*Neurologisches Centralblatt*, November 15, 1898; *Medical Review of Reviews*, February 25th) describes a new instrument for measuring the perceptivity of the hair—the electric trichæsthesiometer. There appears to be a practical field for the instrument, as the author is satisfied that perception by the hair amounts almost to a special form of cutaneous sensibility, in that it differs radically both from ordinary tactile and general sensibility. It is further apparent that in some diseases hair sensibility is lost outright, while in others it is greatly augmented; yet in these same diseases tactile and general sensibility may not be subjected to any alteration.

Injections of Gelatin in Aneurysm.—Dr. Harold Moyer (*Medicine*, March) says that a review of the recent literature justifies the following conclusions: 1.

Gelatin solutions are of some value in the treatment of saccular aneurysms. 2. They are of no value in diffuse enlargements of a vessel. 3. The remedy is used empirically, the experimental work affording little or no basis for the treatment. 4. Solutions not stronger than one per cent. should be used. 5. Great care should be exercised in technique; failures in asepsis are easily made, as the solution is a good culture medium. The solutions should be kept in a brood oven to determine bacterial growth. 6. There may be dangers in the treatment, but the observations heretofore made are insufficient to indicate what they are. 7. Absolute rest in bed should be enjoined, and other remedies suitable for these cases may be given at the same time. 8. It is not a cure for aneurysm, but may rank in the future as a treatment. 9. The method is worthy of more extended trial.

The Arterial Tissue Elements.—Dr. George Burgess Magrath (*Journal of the Boston Society of Medical Sciences*, February 7th), as the result of investigations conducted in the Sears Pathological Laboratory, arrives at the following conclusions:

"1. The elastic tissue of the aorta consists of a system of richly branched fenestrated bands or plates, circular in direction, except the innermost, which is longitudinal, and concentrically placed in the tunica media; and an interlamellar meshwork of elastic fibres derived from the processes of these plates. 2. These structural characteristics are practically constant for different levels of the aorta. 3. The elastic tissue of the aorta of the child differs from that of the aorta of the adult in that the lamellar or plates are placed more closely together, are more fibrous, thinner, and present smaller fenestrations, and the fibres and spaces of the interlamellar meshwork are smaller in the former than in the latter. 4. The elastic tissue of the arteries varies in character and distribution, justifying the recognition of several types of structure. 5. These structural characteristics are constant for different periods of life. 6. The distribution of elastic tissue in the arterial wall probably bears some relation to the function of the vessel."

The Absorption of Iron.—Dr. A. E. Austin (*Boston Medical and Surgical Journal*, March 2d) thus concludes an exhaustive paper on this subject:

"If the difference between the amount of iron ingested and the amount eliminated represents the amount retained in the body and hence absorbed, then there can be no question from these experiments in regard to the absorption of the iron of the blood when taken either in the form of hæmoglobin, as in the meat, or as hæmatin in the preparation used. This assumption also appears as fully justified as that the amount of nitrogen in albuminous food taken less the amount of nitrogen in the feces and urine represents the amount of the same element taken on by the body in the form of tissue, and this principle has been assumed as proved by all physiologists who have been engaged in experiments on metamorphosis. This also substantiates the views held by Kolbert in regard to the absorption of the blood. Considering that the amount of iron retained in the third period from the meat was proportionally as great as in the second, then the amount of iron retained from the 2058 grains contained in the hæmatin preparation must have been at least 0.0152 gramme, or 7.30 per cent. a very small portion, it is true, but it does not indicate necessarily the total amount absorbed. In applying the same calculation

to the beagle we would find that out of 0.0774 gramme in the albuminate at least 0.0026 gramme, or 3.3 per cent., was retained; hence we can not from this say absolutely that iron albuminate is not absorbed, but that the amount retained is only one half of that in the hæmatin; of the ferrous sulphate it is quite evident in this experiment that none was retained, and hence probably none absorbed. A brief summary of this work will establish the following points:

"1. That iron is constantly being eliminated both in urine and faeces even during fasting.

"2. That apparently raw meat furnishes an available form of iron for absorption under normal conditions.

"3. That inorganic iron as represented by ferrous sulphate is non-absorbable.

"4. That albuminates and peptonates of iron are absorbable but to a limited extent.

"5. That organic iron, of which hæmatin and hæmoglobin are representatives, furnishes the most easily absorbable and most valuable of all iron preparations."

Surgery among Birds.—According to the *Medical Times* for March, some interesting observations relating to the surgical treatment of wounds by birds are quoted in *Our Dumb Animals* as having been recently brought before the Physical Society of Geneva by M. Faio. He mentions the case of a snipe which he has often observed engaged repairing damages. With its beak and feather it makes a very creditable dressing, applying plasters to bleeding wounds, and even securing a broken limb by means of a stout ligature. On one occasion he captured a snipe which had on its chest a large dressing composed of down taken from other parts of the body and securely fixed to the wound by the coagulated blood. Twice he had brought home snipe with interwoven feathers strapped on the site of fractures of one of the limbs. The most interesting example was that of a snipe, both of whose legs he had unfortunately broken by a cruel shot. He recovered the animal only on the day following and found that the poor bird had contrived dressings and a sort of splint to both limbs. In carrying out this operation some feathers had become entangled around the beak, and not being able to use its claws to get rid of them, it was almost dead from hunger. In a case recorded by M. Magnin, a snipe that was observed to fly away with a broken limb was subsequently found to have forced the fragments into a parallel position, the upper fragments reaching to the knee, and secured them there by means of a strong band of feathers and moss intermingled. The observers were particularly struck by the application of a ligature of a kind of flat-leaved grass wound round the limb, of a spiral form and fixed by means of a sort of glue.

The Misericordia; a Surviving Mediæval Ambulance Service.—The Rome correspondent of the *Lancet* in its issue for February 25th gives the following interesting account of this ancient institution:

"When the *Romanesque of Outdoor Relief* comes to be written it will owe one of its most touching, most picturesque chapters to the Misericordia—a brotherhood peculiar to Tuscany, and at its best in Florence, though at considerably an *exile* at Siena, Pisa, Lucca, and elsewhere, and represented in the minor provinces by a *convalescent* or *maritime*. Each is tied in origin, it was founded in 1344 by Pietro di Luca Borini and his *permanence* drew from every social rank, all and

individually bound to serve whenever summoned, without fee or reward. The Grand Duke himself, when presiding at a State banquet in the Pitti Palace, has had to rise and leave his guests when his turn came and to bear a hand with tradesmen, nobles, mechanics, professional men—with the company, in fact, promiscuously improvised to transport to hospital some victim of an accident or to carry a patient from the sick bed to the suburban lodging indicated by the physician. The service is not one of 'unskilled labor.' The members of the brotherhood have all been previously trained to lift the sufferer from the street, to turn the patient in bed, and put him on the 'bara' or stretcher with the minimum of pain or of risk to compromised limbs or organs, and thereafter to bear him through the thoroughfares to his destination with the least possible vibration, friction, or disturbance. As often happens, the particular company told off on sudden duty is composed of men as various in altitude as they are in social position, so that in carrying the 'bara' shoulder high they employ for the first part of the journey those of them who are as nearly as possible of the same height, and when these are tired they lower their burden to the less tall without interruption of movement or alteration of pace, and so continue the shifting process till the sufferer is at his journey's end and laid down in bed with scarcely the consciousness of having been transported at all. Few sights or sounds are more impressive in the Florence of to-day than the 'measured march' of the Misericordia through its crowded streets, as robed in black gowns and hooded in black cowls with openings for the eyes the brotherhood wends its way with its burden, the bystander lifting his hat sympathetically, the traffic reverently falling aside, and the street noises subdued to a momentary hush in presence of

"The still, sad music of humanity."

An Unfeeling Jest.—From St. Louis, Missouri, to India and back is a long way, but the *Indian Medical Record* for February 1st is responsible for the following:

"Doctor," said Pat to Dr. Marks, of the St. Louis City Hospital, "I hain't had no feelin' in this yere leg for twenty years." "Well, let's see it," replied the doctor. And Pat, pulling up his trousers, exhibited a wooden leg.

Medical Gleanings from Roman Egypt.—The *Lancet* for February 25th says that it is probable that no archaeological literary discovery of the expiring century will in future be so celebrated as the rescue from the sands of the Egyptian Fayoum of more than ten thousand complete and fragmentary papyri by the explorers acting under the auspices of the "Græco-Roman Branch of the Egyptian Exploration Fund," a society which at its commencement owed much to the late Sir Erasmus Wilson. A selection from some fourteen hundred documents, the greater part of which are at Oxford and the minority at the Ghizeh Museum, has been made by Messrs. Grenfell and Hunt, who have carefully edited about a hundred and fifty of them and published them with a commentary in a volume entitled *The Oxyrhynchus Papyri: Part I, with Eight Facsimile Plates*. First in importance is the now famous portion of a "Logia," or collection of "Sayings of our Lord." There are also pieces by Sappho, Thucydides, Plato, and other classical writers. The first papyrus of medical interest is No. 39, which is from the military archives of Oxyrhynchus.

-chus, and is the certificate for the release from army service of one Tryphon because of defective eyesight. It reads thus: "Copy of release, dated and signed in the twelfth year of Tiberius Cláudius Caesar. Release from service was granted by G. Vergilius Capito, prefect of Upper and Lower Egypt, to Tryphon, son of Dionysius, weaver, suffering from cataract and shortness of sight, of the metropolis of Oxyrhynchus. Examination was made at Alexandria." Another papyrus gives an account of a lawsuit relative to the identity and the custody of an infant who had been placed with a baby farmer. Papyrus No. 51 is the report of a medical officer upon a case of suicide and is dated A.D. 113. A similar document is to be found in the large collection of Greek papyri in the Berlin Museum. The present one is as follows: "To Claudianus, strategus, from Dionysius, son of Apollodorus, son of Dionysius of Oxyrhynchus, public physician. I was to-day instructed by you through Heraclides, your assistant, to inspect the body of a man who had been found hanged, named Hierax, and to report to you my opinion upon it. I therefore inspected the body in the presence of Heraclides at the house of Epagathus in the Broad-Street quarter and found it hanged by a noose, which fact I accordingly report."

Puerperal Convulsions in both Mother and Child.—

Dr. A. Barnes Hughes (*British Medical Journal*, February 25th) says that while attending a primipara of whom he had no previous knowledge he found a first cranial presentation and the os well dilated. He ruptured the membranes and a few sharp pains brought the child down to the outlet. During a pain the woman became convulsed, tonic and clonic spasms being well pronounced, and lividity over the whole body. She remained absolutely unconscious, even after the clonic spasms had passed away. He was able to feel the clonic spasms of the child *in utero*. During a pause he delivered her on the back by means of Simpson's forceps, but this act brought on another fit, and on the birth of the child—a very small one—he found that it also was in convulsions and remained so for a period of from fifteen to twenty seconds, the spasms passing away from both mother and child at the same time. The placenta was removed naturally.

The patient remained unconscious for an hour and a half, having a fit at intervals of half an hour. At this point an idiotic expression passed over the patient's face, and she sprang up in bed and attempted to tear the face of the nurse. By restraint, and the absence of the nurse, the patient was quieted. He then injected subcutaneously a third of a grain of morphine and an eightieth of a grain of atropine, and with the exception of one fit, she remained quiet but unconscious for five hours. Then a succession of fits supervened, six taking place in half an hour. He further injected subcutaneously a quarter of a grain of morphine, and she then seemed to sleep.

At eight o'clock next morning she was still sleeping, and had had no recurrence of the fits during the night. She woke as the doctor called at 11 A.M., and recognized him and the nurse, and, though in a dazed condition, was able to converse rationally. From that time on she made a quick recovery. She was unable to pass her urine for two days, necessitating the use of the catheter. On the third day the temperature was 100° F., and he then douched the uterus. He put her on a sedative mixture, and had belladonna plasters ap-

plied to the breasts, and she made an uninterrupted recovery. On the fourteenth day he visited her for the last time, and found mother and child doing well.

The Clinical Significance of Fatty Stools.—Zoja (*Clinica medica italiana*, 1898, p. 589; *Gazette hebdomadaire de médecine et de chirurgie*, February 26th) emphasizes the necessity of clinically distinguishing between saponaceous and fatty stools. Saponaceous stools, improperly called acholic, he says, owe their peculiar appearance to the presence of a large quantity of insoluble soaps and fatty acids; while fatty stools contain fats recognizable macroscopically, and are the highest expression of dyspepsia. These forms have different clinical significations. Fatty stools indicate chiefly the absence of the pancreatic juice, whether primary, or associated with a lesion of the mucosa of the glandular duct, or with occlusion of the choledochus. Saponaceous stools indicate a trouble of the absorbent apparatus, or, when they coexist with signs of biliary occlusion, the absence of bile in the intestine, or the two conditions combined.

The Relation between Maternal Diseases and the Development of the Fetus.—M. Charrin and M. Nattan-Larrier (*Presse médicale*, February 23d) presented at a recent meeting of the French Society of Biology the case of a young woman of nineteen years who succumbed in the course of typhoid fever of hypothermic type to cardiac syncope. This patient, in the seventh month of pregnancy, gave birth a few hours before her death to a child weighing only a little over two pounds (about thirty-four ounces and a third) which survived forty-eight hours. At the autopsy thereon were found lesions of the heart and of the liver, which latter was in a state of fatty degeneration. The intestine and the liver contained *Staphylococcus aureus* and *Bacillus coli*.

This observation tends to show to what an extent the mother's diseases may influence the development of the fetus.

The Treatment of Hysteria in Children.—Dr. Edward E. Meyer (*Pennsylvania Medical Journal*, February) thus concludes a paper on Hysteria in Children, dealing exhaustively with the subject:

Happily, he says, with children, the disease once recognized, the treatment is easy. The more strange, bizarre, and unstable the symptoms the better the prognosis. Charcot has said of hysteria, the older the woman the harder the cure. We can inversely say, the younger the child the easier the cure. This follows from their being so susceptible to suggestion. We have repeatedly said that hysteria is a psychosis. We know that it is accompanied by diminution of inhibitory force of cerebral activity, provoking thereby diminution of volition. This promotes suggestion and auto-suggestion. By working upon the latter we can alter the moods, help to increase the volitional powers and diminish the imaginative. From this it clearly follows that the treatment is normal.

A psychic disease, the treatment is psychical. In fact, medicinal treatment is not only often futile but may be harmful. Make the parents, if possible, realize their responsibility and the effects of their influence in the future progress of the malady. No feignedness, no submission to the caprices of the child, not too much rigor, and especially no corporal punishment. Too much severity is as bad as too much love. But the parents are too often unable to carry out such injunctions.

Then we have only one alternative—isolation from home surroundings. This does not mean from other patients, but simply separation from home influences. This is to many a hard point. They will ask, Why isolation in a hospital? Why not at home? They assure you that they will do whatever you say; that they can watch and attend to the patient better than strangers. You can not make them understand that the patient is harming them as well as itself. O. W. Holmes once remarked: "An hysterical girl is a vampire sucking out the blood of the people around her." Never promise a cure without isolation; do not use halfway measures, for so you only injure yourself. The child brought to a hospital realizes itself alone, it can not call on weak parents to act against the physician. Stop all visits, even letters. It finds it will not get home until cured; the new surroundings, a strange physician—all these suggestions work wonders. The family doctor is really in such cases the best physician, as he knows and understands the family and can watch the growth of the child and direct its education; but if he does not take the upper hand from the first, or allows the mother's word to have any influence, woe to his treatment! It is as disastrous as if he did not understand the case. He will not succeed, but will lose prestige, friends, and money. If unsuccessful, a specialist is called in at his or the mother's suggestion. The latter is firm, isolates and cures. Not from superior knowledge, but, being supposed to be an authority, his word is law.

Of course, there are other indications to meet. Careful dieting is invaluable. The food must be light and nourishing and may include meats and greens, but milk and fruits are the chief articles to depend upon. A daily bath or douche should be ordered. The shower and cold plunge—the latter at a temperature of about sixty degrees, for from five to ten minutes, the cold jet and cold affusions being the most important. Cold frictions, a wet pack, a Charcot douche, or a Scottish douche may all be found useful, consideration being paid to the age, vitality, and present condition. Massage and electricity, on account of their suggestiveness more than from any action in themselves, should be used. Hypnotism—often dangerous in adults—should never be used in children. The author has, however, seen the transferred system as practised at the Salpêtrière do much good. When anæmia, debility, or other diseases coexist, they should, of course, be counteracted by appropriate remedies. For hysteria, if drugs are to be used, the best are the copper salts, gold and silver chloride, and the valerianates or the sumbul preparations. Gowers recommends turpentine, and others asafœtida, but their efficacy lies largely in their taste and odor.

In regard to prophylaxis, the author states that though hereditary influences are of some moment as a causal factor, still, environment and improper education, by developing a neurotic tendency, do still more harm. Yet he thinks that only State intervention could accomplish anything. It is true that by promoting public hygiene, by exercising control of the ventilation of homes, by creating public baths, by erection of sanitary closets and good sewerage, by controlling the liquor traffic, and by public schools, it does much good. But, unfortunately, its function can not go further. It can not control drunkenness, intermarriage of neurotics, and ill-treatment of children, so that a prophylactic treatment can never be fully realized. Education, he says, is of great moment, public schools being the best.

There the child is less liable to be surrounded by weak children, and is less liable to become a victim of the epidemics of hysteria, so often seen in convents, pensions, and boarding schools. The number of hours and the time of school are also important questions. The question of exercise rightly receives attention. We know that excessive corporal exertion induces nervous exhaustion as well as excessive mental labor. The State, then, can do much, but not all. It can save us from such epidemics of hysteria as in the days of Salem witchcraft, though it can not stop hysterical camp meetings, or the Gautamas seeking after Nirvana; but by good discipline and careful education, the parents can be made to supplement the efforts of the State and to promote self-control of their offspring.

The physician should seek to direct the education and development of the children brought under his care, but he should be more alert to recognize hysteria and its manner of treatment than heretofore. How often have splints, casts, and embrocations been applied to hysterical joints, or tenotomy been about to be performed, or tumors excised, when under narcosis the contracture and swelling disappear! How often did men like Mollinger and Kneipp, how often places like Lourdes and Tries, cure patients after physicians had tried and failed! Let the physician recognize the importance of suggestion in therapeutics, and he can do what enthusiastic charlatanism has done for years. "No hysteria; no quackery," says Strümpell, and he is right.

Paralysis following Cerebro-spinal Meningitis.—Dr. W. N. Bullard (*Boston Medical and Surgical Journal*, February 16th) calls attention to certain forms of paralysis occurring in the course of cerebro-spinal meningitis and continuing after the acute stage of the disease has passed. These differ clinically from the ordinary forms of paralysis in certain respects and do not entirely correspond to the other forms of paralysis which are commonly described in connection with this disease. All his cases have occurred in children.

These cases, while at times and in certain stages precisely resembling cases of paralysis in anterior poliomyelitis, are to be distinguished clinically from the paralyzes of infantile paralysis by the following conditions:

1. In cases of paralysis following cerebro-spinal meningitis we find that pain on passive motion of the limbs persists to a degree rarely, if ever, found in anterior poliomyelitis. Such pain and tenderness sometimes exist during the acute stage of anterior poliomyelitis for two or three days, but if they last much longer than a week he is inclined to consider the case as one in which the diagnosis is to be very carefully examined. It is not uncommon, on the other hand, for great pain, on passive motion of the limbs or of certain joints, especially the ankles, to exist in cerebro-spinal meningitis one, two, or more months after the acute stage of the disease has ceased. Tenderness on pressure over the muscles also persists much longer than in anterior poliomyelitis, where it rarely continues much beyond the acute stage, but it does not last as long as the pain on motion, active or passive.

2. The character of the paralysis also differs, at least in the early stages, although later it is often nearly indistinguishable. There is always a tendency to spastic contracture in the early stages of the paralysis of cerebro-spinal meningitis. This is sometimes so marked that it is evident on casual examination—cer-

tain portions of the limbs are flexed and there is a decided muscular resistance to passive motion due to a permanent tonic contraction. More often, and particularly in the later stages, this tonic or spastic condition is not so evident and shows itself only or principally in the extreme degree of flexion (extension) at the ankle joint, the foot often being in a position of equinus, its axis almost in direct continuance of that of the leg.

3. The knee-jerk is, on the whole, less affected than in anterior poliomyelitis. In other words, there seems to be a greater tendency to retain the knee-jerk. This is rather a question of degree than of anything else, and may have been accidental in our patients. He lays stress on it only in connection with other symptoms. The knee-jerk is sometimes in this affection, as in anterior poliomyelitis, totally abolished.

4. In addition to these clinical signs we have the history of the initial attack to guide us. While certain cases occur in which it is difficult to determine the character of the initial attack, as a rule the existence of the retraction of the head and of contractions of the muscles of the back or limbs, the continued presence of extreme tenderness or pain on movement, and the duration of the acute stage of the disease enable us to determine more or less accurately the character of the case.

He has been accustomed to regard any case as suspicious in which the acute stage lasted more than seven days.

In conclusion, he draws attention to the fact that the conditions in these cases closely resemble, if they are not identical with, those reported in certain epidemics of so-called anterior poliomyelitis, and to suggest that in some of these the disease, which assumes a more fatal course than is usual in anterior poliomyelitis, may really be cerebro-spinal meningitis.

He has recently seen one of the cases attacked in the Cherryfield epidemic, and its present condition would, he thinks, tend to confirm the above view.

Berberine in the Treatment of Malarial Swelling of the Spleen.—Tippaldo Lasarato (*Grice medicale*, January; *Independence medicale*, February 224) says that berberine, in addition to its bitter tonic action, has the faculty of causing the elastic fibres of the spleen to contract, especially when that organ is enlarged, in a manner similar to that of ergotone on the muscular fibres of the uterus. This is not entirely free from danger, as, if it is not administered with caution, its action may be so severe as to rupture the swollen spleen and cause fatal hemorrhage. But berberine, by rapidly and abruptly contracting the parenchyma of the spleen, drives from it *en masse* the paludal parasites which swarm in it toward the general circulation, from which arises a fresh access of pyrexia. The administration of berberine has often been known to be followed by a brusque elevation of temperature. Many physicians have on this account considered berberine more harmful than useful. However, the author points out, the action of berberine in driving the parasites from the spleen, which is their place of election, into the general circulation is very favorable to the complete destruction and disappearance of the paludism from the entire organism. The parasites expelled from the parenchyma of the spleen are pushed through the general circulation at a very inopportune period of their evolution, when they engage in a deadly struggle with the phagocytes of the blood to which they are succumb. To and this result, the Italian physicians, who have had considerable experience with the

remedy, advise its use always simultaneously with quinine, which attacks them more readily in the blood when driven out by the berberine from the spleen. In all cases of swollen spleen, therefore, save those of too old standing or the ultimate result of advanced hypertrophy or degeneration of the organ, berberine is highly commended by the author. It is given in a daily quantity of from a grain and a half to fifteen grains, according to the age of the patient, and always in combination with quinine. A favorite Italian prescription is as follows:

R Hydrochloride of berberine 15 grains;
Bisulphate of quinine ½ “

M.

To be divided into four powders, and one taken every half hour or hour, for an adult.

The Relations between Pure and Applied Science.—

The president of the Geological Society of America, in his presidential address (*Science*, January 13th), made the following trenchant remarks:

“We given all honor to applied science, yet we can not forget that it is but a follower of pure science. The worker in pure science discovers; his fellow in applied science utilizes; the former receives little credit outside of a narrow circle; pecuniary reward is not his object and rarely falls to his lot; the latter has a double possibility as an incentive, large pecuniary reward and popular reputation in case of noteworthy success. The two conditions are well represented by Henry, the investigator, and Morse, the inventor and promoter.

“Men are ignorant of their debt to closer workers because the facts have never been presented. As geologists and as citizens of no mean countries we ought to present this matter clearly to men whose fortunes have come through application of principles discovered by obscure workers. Such men are quick to perceive the justice of the claim and usually are ready to pay a reasonable interest on the debt.

“The world must advance or retrograde; it can not stand still. Continued advance in physical comfort and intellectual power can come only through intense application to investigation along the lines of pure science, which can be made possible only by affording increased opportunities for research in our colleges and by the expansion of research funds held by societies such as this.”

An Extraordinary Fraudulent Charge of Rape.

The *Gazzetta medica* of *La Capitale* for February 20th, contains the *Grice medicale* of a new case, records an extraordinary case: A beautiful young girl of eighteen was brought by her parents to the University of Turin and entered a complaint that she had been raped by a young man to whom the girl was attached. The girl, a noble, Sicilian, proved that he should be considered her lover. The crown prosecutor ordered Dr. G. and Dr. M. to proceed to make an examination of the girl, in order to establish the fact of the crime. Next day, at the first hearing of the case, the witness, Dr. G., testified that the girl was not a virgin, but that she had been raped by a young man; but the doctors found blood in the girl's drawers and then, etc. The expert, Dr. M., who was also present, and slightly indisposed, testified that he had not found blood. However, on account of the fact that the girl's drawers had been found with blood on them, the court decided in favor of the young man, and he was sentenced to prison. The case was then closed, and the girl was released. The case was a very extraordinary one, and it was a very interesting one to read about. The girl was a noble, Sicilian, and she was attached to a young man. The crown prosecutor ordered Dr. G. and Dr. M. to proceed to make an examination of the girl, in order to establish the fact of the crime. Next day, at the first hearing of the case, the witness, Dr. G., testified that the girl was not a virgin, but that she had been raped by a young man; but the doctors found blood in the girl's drawers and then, etc. The expert, Dr. M., who was also present, and slightly indisposed, testified that he had not found blood. However, on account of the fact that the girl's drawers had been found with blood on them, the court decided in favor of the young man, and he was sentenced to prison. The case was then closed, and the girl was released. The case was a very extraordinary one, and it was a very interesting one to read about.

picious of fraud and were led to the belief that the defloration had been artificially produced with the object of accusing the young man, which opinion was strengthened by the girl's mental state. They therefore proceeded to a vaginal examination. In the vagina they detected an ovoid body, smooth and movable. In attempting to remove it, it broke, and from the colored material that ran down the girl's thighs they recognized that they had broken a hen's egg. It transpired that the girl's parents, knowing that the young man had declined a marriage, had adopted this means, after a family council, to consummate their desires.

Christian Science Moneymaking Methods.—The *Christian Science Weekly* for January 19th contains the following impudent demonstration of its character as a barefaced moneymaking scheme:

"Christian Science Souvenir Spoons."

"On each of these most beautiful spoons is a motto in bas-relief, that every person on earth needs to hold in thought. Mother requests that Christian Scientists shall not ask to be informed what this motto is, but each Scientist shall purchase at least one spoon, and those who can afford it, one dozen spoons, that their families may read this motto at every meal, and their guests be made partakers of its simple truth.

"MARY BAKER G. EDDY.

"The above-named spoons are sold by the Christian Science Souvenir Company, Concord, New Hampshire, and will soon be on sale also at the Christian Science reading rooms throughout the country."

A Journal of Military Sanitation has been started in Buenos Aires. It is an octavo monthly of sixty-two pages entitled *Anales de Sanidad Militar*, edited by Dr. Marcial V. Quiroga.

The Regulations concerning the Sale of Patent Medicines Abroad.—By the courtesy of Messrs. Merck & Co. we are enabled to give the following summary of the patent-medicine laws in several foreign countries.

Austria-Hungary.—Prepared medicines, whether patented or not, unless imported for druggists, require a special permit from the customs authorities. All medicines and medical compounds are excluded from protection by the Austrian patent law, and the sale of such is permitted only to and in drug stores.

Belgium.—Patent medicines can only be sold by apothecaries or other authorized persons, and must bear the seal of the seller, who assumes the responsibility of the product.

Denmark.—The regulations in this country are very stringent. Both the importation and sale are confined to apothecaries, who may be said to hold a monopoly.

France entirely prohibits the sale of patent medicines, or, as they are called there, "secret medicines," unless such preparations are approved by a competent authority and the formula inserted in the code.

Germany.—All proprietary medicines must be retailed by a licensed apothecary, who is responsible for their effect; but the most serious restriction is the prohibition of patent-medicine advertisements in public journals, when such medicines are made by a secret formula or process. This law is vigorously enforced in Baden and in Prussia, but less stringently so in Württemberg, Bavaria, and some parts of northern Germany, while in Saxony the authorities exercise the right of prohibiting the sale altogether.

Italy.—The regulations as to patent medicines are identical with those of ordinary drugs, and in either case a statement of the composition thereof must be previously given to the board of health and its approval obtained.

Russia.—No patent medicine is allowed entry into Russia unless special permission is on each occasion obtained from the medical department of the ministry of the interior. If, after careful examination, it is proved that the production of such medicine requires elaborate work and expensive apparatus, it is allowed entry subject to a duty of about forty cents a pound avoirdupois, provided the medicine is regarded as beneficial.

Sweden.—The laws as regards patent medicines are very old and not generally in force. According to later decisions no private person, except a licensed apothecary, may import medicines of any kind without permission from the board of health or under certain restrictions for scientific purposes. Most medicines are free from duty; but advertising, except by an apothecary, is prohibited.

Switzerland.—No federal law beyond the tariff exists as to patent medicines, the sales being regulated by the ordinances of the different cantons.

Turkey is a far more promising country for patent-medicine manufacturers, as only a stamp tax of two cents for every bottle, box, or package of medicine is required. Except chlorodyne, cigarettes of cannabis indica, nitroglycerin, collodion, and chloride of potassium, medicines of any kind may be imported and sold in the country.

The College of Physicians of Philadelphia.—At a meeting of the Section in Ophthalmology, held on February 21st, Dr. C. A. Veasey exhibited a patient with atrophic retino-chorioiditis and incipient angeioid streaks in the retina; Dr. G. Oram Ring reported a successful case of iridocystectomy according to Knapp's method, and showed a patient with rupture of the chorioid and optic nerve from a baseball injury; Dr. David Riesman presented a case of day-blindness; and Dr. de Schweinitz described cases of chorioiditis and retino-chorioiditis with unusual ophthalmoscopic appearances, a case of cured sympathetic iritis, and a case of almost total detachment of the retina of three months' standing in which forty-eight hours of dorsal decubitus were followed by complete reattachment and restoration of function.

Echthol in the Treatment of Erysipelas.—Echthol, which is described as containing the active principles of *Echinacea angustifolia* and *Thuja occidentalis*, has been employed by Dr. Robert C. Kenner, of Louisville, in twenty-two cases of erysipelas. For adults he prescribes a teaspoonful every two to four hours; in very mild cases, every six hours. In severe cases he would begin by giving teaspoonful doses every hour until some manifest impression is made on the disease. All his patients treated with this preparation did well. He lays stress on seeing that the patient gets an adequate amount of nourishing food and on the use of local treatment. As an application, he advises a solution of potassium acetate, fifteen grains to the ounce of distilled water. This is applied every hour or two.

A New Italian Journal, entitled *Gazzetta internazionale di medicina pratica*, has made its appearance. It is a monthly quarto of sixteen pages, published in Naples.

TREATMENT OF ECZEMA
IN INFANTS AND CHILDREN.*

By CHARLES WARRENNE ALLEN, M.D.,

MEMBER OF THE AMERICAN DERMATOLOGICAL ASSOCIATION
AND OF THE NEW YORK DERMATOLOGICAL SOCIETY;
CONSULTING DERMATOLOGIST TO THE RANDALL'S ISLAND HOSPITAL,
TO THE ITALIAN HOSPITAL, TO THE HACKENSACK (N. J.) HOSPITAL,
TO THE BAYONNE (N. J.) HOSPITAL;
ATTENDING SURGEON (DEPARTMENT OF SKIN), GOOD-SAMARITAN DISPENSARY,
CONSULTING SURGEON (GENITO-URINARY DIVISION)
TO THE CITY HOSPITAL, NEW YORK.

THE paper upon the diagnosis and forms of eczema to which we have just listened makes the part allotted to me possible.

I would not have ventured to present a brief paper upon the treatment of eczema unless the question of what eczema is and what it is not had been previously defined.

Infantile dermatitis, beginning with the erythema of the newborn and extending through the papular, vesicular, and bullous forms of childhood, including the impetigo and pustular dermatitides due to the irritation of pediculi and insect bites, as well as the irritated and secondarily inoculated lesions of urticaria and a number of other conditions, have been and continue to be confounded with eczema proper.

The eczema, which has so long figured in dermatological statistics as furnishing one third of all cutaneous disorders, has unquestionably included many dermatoses in which some external visible and tangible irritant has been at work, but which otherwise conformed to the requirements of redness, itchiness, exudation or moisture, and scabiness. When this rather large class of dermatitis is excluded we find that the sum total of eczema proper is materially reduced.

In the American Dermatological Association statistics for 1879 about one third of the cases were put to the credit of eczema; in the report of 1897 the ratio was about one in four; while in my personal statistics for last year in five thousand cases reported there were but about a thousand instances of eczema, or one in five.

There are some general principles which underlie the treatment of eczema which remain the same no matter what the etiology may be, and therefore apply equally to dermatitis. In these are to be included superintendence of the clothing, especially that which comes next to the body, with special reference to the degree, regulation of the bath and daily washing, re-education of the nursing periods, examining the mother's milk for quality and quantity; the prevention and correction of intestinal derangements on the part of both infant and mother, including constipation in the latter, and the protection of the infant's delicate cutaneous tract

from those irritations which may arise from various causes, including soap, water, sun heat, and cold winds. Newman has recently stated that the infant's first bath should be given only after the umbilical wound had healed. While there is no question that the matter of early bathing is often much overdone, still I know from a personal experience, in which I have myself given the first bath to many infants and have superintended it in many others, that the bathing can be carried out without injury from the day of birth. I will not presume to suggest before this audience the precautions in regard to the temperature of the water, the amount of friction, the use of coarse towels, irritating soaps, etc.

Soap is unquestionably often at fault, and it was only to-day a mother brought a child with beginning eruption upon the cheeks, and suggested that a new glycerin soap might have determined the eruption, because she had afterward tried it on her own skin and found it caused an itching.

Another general statement may be made to the effect that infantile eczema requires nursing and proper intelligent management quite as much as and often more than it needs the physician's prescription. A generalized eczema often requires the services of a trained nurse quite as much as a case of pneumonia does, if we are to expect a prompt cure.

The secret of success in treatment lies often in knowing not to stimulate when you should soothe and in picking cases which require antiparasitic remedies.

One very large class of cases which has been at times carelessly designated as belonging to the impetiginous or crusty form of eczema I believe should be called more properly impetigo contagiosa. Although I recognize a form of eczema with tendency to the formation of impetiginous crusts, I believe that often confluent lesions about the mouth, chin, and other portions of the skin surface which are associated with pediculosis of the scalp are usually eczemas which have become secondarily inoculated with pus organisms, the latter having developed in connection with the condition of looseness. In my recent clinical work I have also made a class by itself of the so-called eczema of the scalp, neck, and back occurring as a direct outcome of the irritation of pediculosis and the scratching occasioned by it, but which oftentimes does not produce typical lesions of impetigo; and to this I have given the name of

Urtica pediculosa, to indicate its etiology. In this way we find a large number of eruptions about the buttocks and genitalia, which are due primarily to, and caused by, pediculosis, and are intensified by irritation caused by the constant peaking, rubbing, and scratching of the inflamed, barbed discharges of the pediculi. These eruptions are kept in a chronic state by the constant irritation of their tiny compound pustules, and are due to their crusts.

* Read by invitation before the Section in Paediatrics of the New York Academy of Medicine, January 12, 1899.

Leaving aside, then, all those conditions which are not, properly speaking, eczema, but whose cause can be directly traced to some external irritation, and confining ourselves to the well-divided classes described in the paper to which we have just listened, we will take up, first, the seborrhoeal form in which the affection presents itself so often in early life.

The fact that infantile eczema shows a decided predilection for certain regions, notably the scalp, forehead, cheeks, the region behind the ears, flexures of the extremities, the neck, and groin, is accounted for largely by this fact of the seborrhoeal element predominating. It seems to me almost the exception to find an eczema, not clearly to be placed in the impetiginous, or in the neurotic, or reflex class, which does not present upon the anterior surface of the scalp in the region of the fontanelle evidence of greasy crusts mixed with exfoliated epidermis; or to have the mother give the history that almost from birth difficulty has been experienced in keeping this region clean and free from scales. In spite of the mother's statement that the head is washed daily, it is by no means uncommon to find large areas of the scalp covered with thick, dirty brown or almost black, greasy cakes. I believe it to be of the utmost importance that, in order to secure good and permanent results in the eczema situated upon the parts lower down, the scalp should be brought back to a healthy state of secretion and kept free from crusts and dirt.

The reason that the cheek, next to the post-auricular, is the region most frequently affected is because we have here what are termed the "flushing areas," or those of greatest vascularization. And the frequency with which the groin becomes implicated would seem to be caused by the very great abundance and activity of the secreting glands in this situation. This might also account for the natural folds being involved, and in fat babies the facilities here presented for retention of the secretions and extraneous dirt undoubtedly assist in determining the localization.

The treatment is almost exclusively local. The health of these children is usually about the average of those of equal age and social station. In nurslings, the mother's breast is taken regularly, or more often irregularly; but, aside from this, as we fail to discover vices of table or vicious habits, we can not fall back upon the much-abused *excessus in vino et venere* as an excuse for not effecting a rapid cure.

For the scalp affection, and for dry, scaly patches elsewhere, resorcin is useful, as it is in the seborrhoeal form of eczema in the adult; it is here equally efficacious, but must be used in much decreased strength, as in the following prescription:

R Resorcin (Mord.)	0.5-1.0
Washed sulphur	2.0-4.0
Catbolol	5.0-10.0
Lard	ad 100.0

M.

As an ointment base nothing seems very much superior to the long-tried zinc-oxide ointment.

In almost all eczemas about the anogenital and groin region during the past year I have been using a three-per-cent. watery solution of methylene blue, and can say without hesitation that here, as well as in erythema intertrigo in infants, it has given me most satisfactory results. The drug is somewhat analgetic, is soothing to the irritated, raw, and sometimes exulcerated surfaces, it forms a protective coating, is antiseptic, and from its discoloration leaves no doubt as to the time when a new coat of the solution is required.

In order to keep the parts free from excreta and urine I instruct the mother or nurse to place the infant regularly at each time of feeding, or every two hours, upon a small vessel with the object of teaching it thus early in life not to urinate in the diaper. If the stream does not follow upon contact of the buttocks with the cold rim of the vessel, the finger nail or any sharp-pointed object drawn from the bladder region to the umbilicus may succeed in inducing urination. In male children I have frequently accomplished this object by painting the glans penis with a drop of cold methylene solution. These methods are, at times, useful in securing a specimen of the infant's urine for analysis, and are much superior to passing a catheter or wringing out a wet diaper.

Methylene blue I have used extensively in a great variety of eczemas and believe it a valuable addition to our means of cure. Upon the exposed parts, however, the color is, in most instances, an objection; and in general the staining of the clothing might be a drawback. In point of fact, the parents are so well satisfied with the results that never has this been raised as a serious objection in any case so treated.

The form of seborrhoeal eczema is more rarely pityriasis with dry desquamation and slight infiltration of the integument. Here mild salicylic and ichthyol applications are of use, as for example:

R Salicylic acid	0.2-0.5
Powdered zinc oxide	10.0
Powdered starch	15.0
Compound tincture of benzoin	10.0
Lard	ad 100.0

M.

Naturally in this, as in any other forms, if any internal derangement is to be made out, it is to be combated by internal remedies. If there is anemia, and especially if the secretions are inactive, or there is at the same time intestinal fermentation, the following tablet, which we owe, I believe, to our worthy chairman, can be given with decided advantage:

R Calomel	gr. $\frac{1}{10}$
Saccharated iron carbonate	gr. $\frac{1}{2}$
Powdered white sugar	gr. ij.

M. S.: One crushed in milk twice a day.

In older children:

R Iron peptonate gr. xl;

Elixir of calisaya 5 ij.

M. S.: A teaspoonful three times a day.

An occasional larger dose of calomel, a sixth to a fourth of a grain, once a week, is often of benefit.

FIG. 1.—Head dressing, or cap and mask in one piece.

If the mother of the nursling is a beer drinker or a tea drunkard, or if she is in a state of ill health, or suffers from habitual constipation, her condition is to be looked after for the benefit of the little patient.

In the impetiginous form, if the crusts are thick and not readily removed by oil or soft soap, I often order a favorite cataplasm of the French made with potato flour (*fécule de pomme de terre*), but I usually order it made with some antiseptic, such as mild bichloride, carbolic acid, or lysol solution, the latter having the advantage of being somewhat antipruritic.

In the more chronic, i. e., persistent, forms of older children, and when there are extensive scaly plaques upon the back of the neck, or involving the margins of the scalp regions behind the ears, etc., I use a stiff, paste-like ointment, as in the formula:

R Resorcin	10
Tar	20
Prepared zinc carbonate, }	
Powdered zinc oxide, }	100
Lanolin	500
Lard	ad 1000

M.

This is an intermediate between stiff pastes and thin ointments without adhesive properties, and has the advantage over ordinary pastes made with starch that in

the latter, when the fat is absorbed by the crusts, the skin, and the dressings, there is left behind a residue of dry, crumbling or caking material, which is apt to act more or less as an irritant, and thus, in a measure, defeat one of the very objects for which it was employed.

When an impetiginous eczema is impetiginous because it has been inoculated with the virus of true impetigo, ammoniated mercury ointment, so useful in the latter, is, in modified strength, here likewise efficacious.

The neurotic, nervous, or reflex eczemas, usually of symmetrical distribution, occurring in young children who are florid, fat, and in fit condition, and in whom no error of diet may be discoverable, is an excessively pruriginous affection, requiring primarily applications which will allay the itching and prevent the scratching which is so pronounced an element in the dissemination and aggravation of the condition. Although attributed to the irritation of cutting the gums, it is seen not infrequently in those who have not yet reached the period of eruption of the teeth. Intestinal irritation may be found, especially if the child has reached the age at which certain liberties of diet are allowed. In the majority of cases reliance must be placed almost wholly upon external measures, and one of the most difficult problems to solve is that of retention of applications in

FIG. 2.—Cap and mask.

situ, and the prevention of moisture becoming and rubbing, especially at night. I have devised for the purpose of retaining dressings on the head and face a little cap with a mask attached, which I now show you. It is made, as you see, from a net, so that by

removing the stitches or safety pins from a single seam it can be used as a pattern from which new caps may be cut out. I find this a necessity, since mothers and nurses, however willing, are often unable to manufacture efficient head dressings. Sheet lint or linen is spread with the particular ointment which you wish to apply in strips of requisite size for the various regions, and over this is placed and securely fastened the cap and mask as devised. Besides this it is necessary to secure the hands to the side by means of safety pins, attaching the sleeve of the nightdress to the diaper. Whatever rubbing against the pillow is indulged in can then do little more than rub in the ointment applied.

There are many interesting conditions which I must refrain from more than mentioning, such as mycotic varieties requiring rather the treatment applicable to ringworm, and contagious impetigo; rare chronic conditions affecting single regions, as the fingers of one hand alone, implicating the nails and bringing about in them changes such as are seen in eczemas of bartenders and washerwomen; eczematoid conditions of the scrotum in scabies, and secondary inoculations resulting in quickly changing vesicles into pustules, the latter being surely more common in infants than in the adult, particularly in the poor and uncleanly.

We can also not do more than to note common complications—the irritation and itching incident to insect and louse bites, intercurrent attacks of urticaria, in which scratching and inoculation result in lesions which add to the already marked multififormity of eczema as it is observed in infantile life and early childhood.

The unprotected patches which become infected by pyogenic cocci still require treatment, but it must now be modified to meet the pustular development and changes in clinical features.

As to internal treatment, my first impressions of therapy in infantile eczema tended toward the theory that there were certain forms which were salutary, and that if healed or cured too quickly some internal disorder would follow.

In post-graduate study in France I was taught that most of these affections were dependent upon certain diatheses or disordered conditions of the system, and I learned the benefits of internal medication, diet, etc.

In Vienna I found that external applications were relied upon almost to the exclusion of internal therapy. Now, after twenty years of endeavor to find out which plan is nearer the truth, I have come to the conclusion that they are all in a measure right. There is external irritation operative in one instance and internal in another; irritation may be excretory or perhaps reflected to the surface from internal organs. At times a rapid disappearance of extensive eczema will be followed by intercalated eruptions, which will cause one to suspect that the surface, after receiving a relief to the particular internal organ, is once more a *terra incognita*. This I know to be

true in certain instances in the adult—gouty manifestations or asthma coming on when a chronic eczema is made to disappear—and I know of no reason why infants should not occasionally react in a like manner; but so rare is it that no one need hesitate to cure a given case in the shortest possible time. I find that the statement to the parents that their offspring's skin eruption must not be too quickly healed comes rather frequently from those practitioners whose ability to effect a rapid cure might come into question. Some cases require external means alone, others internal measures at the same time, but the great majority will do best under a judicious combination of the two.

126 EAST SIXTIETH STREET.

THE PREVENTION OF DEFORMITY AFTER EXCISION OF THE KNEE IN CHILDREN.*

By WISNER R. TOWNSEND, A. M., M. D.,
PROFESSOR OF ORTHOPEDIC SURGERY IN THE NEW YORK POLYCLINIC;
ASSISTANT SURGEON,
HOSPITAL FOR THE RELIEF OF THE RUPTURED AND CRIPPLED;
CONSULTING SURGEON, RAYSONE HOSPITAL;
ORTHOPEDIC SURGEON, FRENCH HOSPITAL.

THE opportunity to observe the results of excision of the knee in children years after the operation is probably growing less each year, because at the present time but few of such operations are done.

In a *Treatise on Surgery by American Authors*, edited by Roswell Park, on page 623, volume i, we find the following: "Resection for tubercular arthritis, formerly very extensively practised, is for good reasons less and less employed. Until the period of puberty has been reached a formal excision should rarely be performed, since the removal of the epiphysis is invariably followed by very great shortening of the extremity"; and on page 640: "In tubercular disease the easy accessibility of the joint fits it particularly for the more conservative operation of arthrectomy and informal or partial excision. In the failure of this, recourse may be had to formal excision. The latter is not called for in young children, and even in youths and adults should be rarely resorted to as the primary operation, except in cases of most extensive destruction by disease."

The above was written in 1896, and may be taken to represent the views of most of the American surgeons of to-day. If we consult the four standard American text-books on orthopaedic surgery we find that Sayre in his first edition, published in 1876, says nothing against excision of the knee in children, but advises against ankylosis in a flexed position, because the solidification is very insecure and is liable at some future date to give the patient trouble. This is a most valuable suggestion, and is universally adopted at the present day.

Bradford and Lovett have a very complete article

* Read before the Orthopaedic Section of the New York Academy of Medicine, November 18, 1896.

in their *Orthopædic Surgery*, and give many valuable data collected from many sources. Their own views are clearly expressed in the following lines: "The functional results after excision are, however, decidedly inferior to the results after conservative treatment. Ankylosis is to be hoped for after excision, and is complicated by a tendency to flexion of the apparently ankylosed joint. Referring to the statistics of Hoffa, in which a hundred and thirty cases were analyzed a considerable time after the operation, and in which fourteen showed slight flexion and thirty severe flexion, they say that "this should make the surgeon very careful about removing splints before there is reason to believe that firm bony ankylosis is present. This generally occurs after the patient has been discharged from immediate supervision."

Moore, in his *Orthopædic Surgery*, in speaking of arthrectomy, says: "This operation should always be chosen for a child, because it will not interfere with the growth of the limb, as excision would."

Young, in a text-book on *Orthopædic Surgery*, published in 1891, quotes Agnew as saying that "excision is always to be preferred for children, and amputation for adults," and he believes that this agrees with the opinions of most surgeons of large experience, the question being largely one of individual judgment. He does, however, refer to the fact that in children where the resection must remove a very large portion of the shafts of both bones, amputation may be considered.

It is unnecessary to further multiply quotations, because the profession is practically in accord on the subject that excision of the knee in children is an operation that should rarely be performed, because the conservative treatment is most satisfactory and gives better results, and because in severe cases, where much bone is destroyed, the removal of so much bony tissue interferes so seriously with the future growth of the limb that the ultimate result is very poor indeed. Where the knee has become septic, and much destruction of soft tissues as well as of the bones has resulted, the more radical operation of amputation is indicated.

The chief reason that excision has been abandoned is on account of the subsequent shortening, and I would like to place on record a few of the cases I have personally seen at the Hospital for the Relief of the Ruptured and Crippled during the last two years. No attempt has been made to collect a number of cases, and therefore it could be very easily increased. I have added one case of shortening that I saw some years ago, but that I have been unable to trace.

The amount of shortening that will follow excision before the age when the lower epiphysis of the femur has firmly united to the shaft will depend upon the amount of bone removed. If the operation is performed that only the bone between the epiphyses and the joint is removed the shortening will be less than where the epiphysis is removed, and the same amount of

removal of the upper end of the tibia. Where there is extensive bone disease, to keep within the narrow limits just referred to is not only difficult but often impossible, if we desire to thoroughly remove all diseased tissue.

Koenig* gives a table of measurements showing the height of the epiphysis from the articular edge of the femur, and also the same measurements for the tibia. Ollier† has also given us similar measurements. The cartilage uniting the epiphysis to the diaphysis follows a line nearly parallel to the lower curve of the condyles, presenting two concavities, which at the age of sixteen are seven or eight millimetres, or a third of an inch, above the periphery, and at the age of five from five to six millimetres. That of the tibia is more nearly straight across and about three or four millimetres from the edge of the articular surface of the bone.

From this it follows that we can not remove a piece of bone from the lower articular edge of the femur more than thirty-five millimetres, or an inch and a half, without invading the cartilage between the epiphysis and diaphysis, from which the growth of bone largely occurs, as the epiphysis grows but little by itself. The union of the epiphysis and diaphysis occurs between the eighteenth and twentieth year of life.

These show very clearly that if the disease of the bone is at all extensive we must remove the epiphysis, and thus interfere with the growth. The earlier in life the operation is done the greater will be the shortening when adult life is reached. If the epiphyses of both femur and tibia are removed, the shortening will be greater than where one alone is removed.

The literature is fairly complete with recorded cases of shortening, and I will only report the few personal cases previously referred to.

CASE I.—A boy. Operation at age of three years. Shortening at age of nine years was six inches. Shortening at age of fifteen years and six months is nine inches and a half. Length of right femur, twelve inches and a half; right leg, eleven inches and a half. Length of left femur, eighteen inches and a half; left leg, fifteen inches.

CASE II.—A boy. Operation at age of two years. Shortening at age of thirteen years was seven inches.

CASE III.—A boy. Operation, age unknown. Shortening at age of fourteen years was seven inches and three quarters. Shortening after supracondylar osteotomy, six inches and a half.

CASE IV.—A girl. Operation at age of two years and six months. Shortening at age of seven years, eight and a half inches.

CASE V.—A boy. Operation at age of one year. Shortening at age of eleven years, seven inches and three quarters.

CASE VI.—A girl. Operation at age of one year. Shortening at age of nine years, eight inches.

CASE VII.—A boy. Operation at age of one year. Shortening at age of nine years, eight inches.

* *Technique des Opérations de Chirurgie Orthopédique*, published in 1867.

† *Leçons de Clinique Orthopédique*, published in 1887.

CASE VIII.—A girl. Operation at age of four years. Shortening at age of ten years was an inch and three quarters.

FIG. 1.

FIG. 2.

FIG. 1.—Case III. Bowleg and flexion deformity. Shortening, seven inches and three quarters, reduced to six inches and a half after supracondyloid osteotomy.

FIG. 2.—Case III. Position three months after operation.

Another objection to the operation of excision, and the one to which I especially wish to refer, is the tendency to deformity after the cases are apparently cured and bony union has taken place.

Surgeons will continue to perform this operation, and all admit that in exceptional instances it may be indicated. The opinion that it should never be performed until union of the epiphyses and shaft has taken place may be advocated by many, but it will not prevent the few from operating. To those who do operate, however, it seems to me that the following cases will clearly show the necessity of subsequent long-continued protection to the joint even after bony union seems perfect.

Not a single patient in whom the excision had been done before puberty has presented himself at the hospital two years after the excision without showing some deformity. In fact, they all came seeking treatment for the deformity, and in none can I learn that protective treatment was given the joint for any great length of time after the operation.

The deformities that may occur are flexion, bowleg, knock knee, and what is known as genu recurvatum, or a bending backward at the knee. Where bowleg is present the patient usually turns the foot in, and in knock-knee turns it out. If the tibia is rotated they may walk on inner or outer side of the foot. Of all these, flexion is by far the most common, and will surely result if at the time of the operation the leg is not put up perfectly straight. The few degrees at first may become many

degrees in after years. It is easily understood that the weight of the body pushing downward on a flexed knee tends to increase the flexion, and the action of the hamstring tendons may tend to increase this, and for this reason many operators always cut these tendons. It is also claimed that the flexion is increased, owing to the fact that in such cases there is less pressure on the anterior surface of the knee and the growth of bone is greater and, owing to lack of pressure, does not become so dense; while on the posterior surface there is increased pressure, greater density, and some interference with growth. The object of placing a limb in slight flexion is to enable the patient to have the ankylosed limb slightly shorter than the other, so as to facilitate locomotion; but this is never necessary in children, because shortening always occurs after the operation, no matter how little bone is removed.

The few cases on record where shortening has not occurred, and the few examples where, after excision, lengthening has taken place, bear such a small proportion to the total number of cases that they need not be considered. The deformity is usually progressive, and may increase rapidly or very slowly. Where it is rapid, usually there was not firm bony union to start with, and in many instances where bony union was supposed to exist it has been subsequently proved to be fibrous or cartilaginous only, yet the limb was perfectly stiff and straight, and the patient had borne weight on it for some time. Such a case is quoted by Ollier.*

FIG. 3.

FIG. 4.

FIG. 3.—Case VIII. Flexion deformity.

FIG. 4.—Case VIII. Result after supracondyloid osteotomy.

For the prevention of flexion deformity it is necessary that apparatus be worn for a very considerable

* *Traité des excisions*, tome iii, p. 265.

period after the operation. This may consist simply of a plaster-of-Paris splint, or of a posterior or lateral splint of some firm material, preferably metal. Where the deformity exists the method of treatment should be to reduce it if possible by slight force, either with or without an anæsthetic. Most cases are better handled with the aid of the anæsthetic. If the union between the tibia and femur is firm and the ankylosis bony without a doubt, too much force must not be used, because a fracture may result or a separation at the point of union of femur and tibia. In such a case it is far preferable to do another excision, or to do a supracondyloid osteotomy. In most cases, if the deformity is excessive, an excision is indicated, and a considerable wedge of bone may have to be removed; but when the deformity is slight, but yet can not be corrected by manual force, an osteotomy may suffice. In connection with the flexion deformity we may have either knock-knee or bowleg, and in such cases we must correct both deformities. This may be done by an excision or osteotomy, or by straightening the flexion and then treating the knock-knee or bowleg by a suitable brace. The particular form of apparatus is not so essential as it is that the treatment should be thorough and kept up for some time. A simple form of apparatus, and one easily worn by children, is the Thomas knee splint, and this can be used to protect the joint, and, by the attachment of adhesive strips to the limb with buckles fastened to straps at the bottom of the brace, traction can be made and flexion deformity overcome where the ankylosis is not firm, or the brace may be worn after an excision with or without the straps. As a protective apparatus the brace may be used with a sliding foot piece. The use of crutches is rarely indicated, for, if the knee is straight and the union between femur and tibia firm, no harm will follow walking if the knee is protected. The following cases showed flexion deformity when admitted to the hospital:

CASE I.—Slight flexion.

CASE II.—Flexion to a right angle.

CASE III.—Flexion deformity of twenty-five degrees.

CASE IV.—Flexion deformity of fifty degrees.

CASE V.—Flexion deformity of twenty degrees.

CASE VI.—Flexion deformity of forty degrees.

CASE VII.—Flexion deformity of sixty-five degrees.

CASE VIII.—Flexion deformity of fifty degrees.

Cases I and III showed bowleg deformity, and Case V was one of knock-knee. In Cases VI and VII slight motion was present. None of these cases showed any recurvatum, but I have seen a case in an adult, and there is no reason why it should not occur after an excision performed in childhood.

Another objection to the operation of excision is that very often sinuses are left and may continue for a considerable length of time. The use of nails in holding the two bones together has been thought by some to be a produce these sinuses, and many do not use them for

that reason. I have also seen sinuses occur, or rather a breaking down at some point of the scar, and subsequent discharge of broken-down bony tissue many months after the wounds had entirely healed. Any little focus of disease left behind at the time of operation may start up fresh trouble even months afterward. Motion may also remain as the result of non-union, and this nearly always means a very weak knee or base of support. Knowing that the removal of the epiphysis will shorten the limb, it has been suggested by Dr. Dawbarn that in such cases at the time we operate we might also destroy or injure the epiphysis of the opposite femur by simply passing some sharp instrument into it subcutaneously, and thus shorten both limbs. I do not know that this has ever been done or that it would prove of any great advantage; it might even produce lengthening, as many cases are on record of increased growth from irritation at or about the cartilage between the epiphysis and shaft. Such a case I have shown the Section in Orthopædic Surgery of the academy, where a man had limbs of equal length until the age of twelve, when some dead bone came away from the lower end of the right femur, and to-day, at the age of fifty-five years, he has a right femur two inches and an eighth longer than the left. It is also a well-known fact that after osteitis of the femur we often get a lengthening. The following brief histories will give fuller particulars of the cases and show what treatment was employed in each case and the result.

For the short leg a patten or cork sole must be worn, and where it is excessive a Symes or some other amputation and artificial limb might even be indicated.

CASE I.—W. M., a boy, six years of age, admitted March 3, 1890. Disease began when he was three years old; operation shortly afterward. On admission had slight flexion deformity and two discharging sinuses. Treatment was local and constitutional; sinuses healed. Knee straightened by manual force under ether.

July 26, 1891.—Six inches shortening.

November 18, 1898.—Nine inches and a half shortening. Has slight bowlegs. Right femur, twelve inches and a half; left, eighteen inches and a half. Right leg, eleven inches and a half; left, fifteen inches.

CASE II.—W. B., a boy, twelve years of age, admitted June 21, 1888. Disease began when he was seventeen months old. Excision at age of two years. On admission had flexion deformity to right angle and firm ankylosis.

July 3d.—Length of right thigh, sixteen inches and a half; length of left thigh, twelve inches; length of right leg, fourteen inches and a half; length of left leg, twelve inches and a half. From right acetabulum superior spine to internal malleolus, twenty-two inches and a half; from left anterior superior iliac to internal malleolus, twenty-three inches and a half.

A wedge of bone was removed from the knee perfectly straightened, and on September 1, 1888, there was seven inches shortening. He wore a patten for the short leg and walked very well.

CASE III.—C. W., a boy, six years of age, admitted March 3, 1898. Disease began in early child-

hood, age not known; had excision shortly afterward. On admission, twenty-five degrees of flexion deformity. Seven inches and three quarters of shortening. Tibia slightly displaced outward. Bowleg deformity.

March 29, 1898.—Under ether, supracondylar osteotomy; plaster-of-Paris dressing.

December 6, 1898.—Six inches and a half shortening; leg straight; wears patten on short leg.

CASE IV.—E. G., a girl, seven years of age, admitted August 29, 1898. Excision at age of two years and six months. Has, on admission, fifty degrees of flexion deformity and half an inch shortening. Under ether, flexion deformity entirely overcome in three stretchings and leg put up straight in plaster of Paris.

November 18, 1898.—Leg straight; shortening is half an inch.

CASE V.—H. P., a boy, eleven years of age, admitted February 15, 1898. Operation at age of seven years. On admission, twenty degrees of flexion deformity and slight knock-knee; three inches and three quarters shortening. Under gas, leg straightened perfectly.

November 18, 1898.—Unable to find the patient, he having left the hospital several months ago.

CASE VI.—M. R., a girl, nine years of age, admitted February 28, 1896. Excision at age of six years. On admission, two discharging sinuses. Flexion deformity of forty degrees.

December 22, 1897.—Under gas, knee straightened.

October 17, 1898.—Sinuses all healed. Knee straight; an inch shortening. Five degrees of motion.

CASE VII.—J. G., a boy, nine years of age, admitted July 14, 1898. Excision at age of six years. On admission, forty-five degrees of flexion deformity. Slight motion in knee. Right femur eleven inches and a quarter long; the left is ten. Right lower leg, thirteen inches; left, twelve. July 28th, stretched to a hundred and seventy-five degrees, or nearly straight. Has a plaster-of-Paris cast and a Bishop brace.

November 18, 1898.—Shortening, two inches; twenty degrees of flexion deformity. Has about ten degrees of motion.

CASE VIII.—M. F., a girl, ten years of age, admitted November 10, 1897. Operation at age of four years. Flexion deformity of fifty degrees.

November 16, 1897.—Supracondylar osteotomy, subcutaneous.

February 25, 1898.—An inch and three quarters shortening; no motion; knee straight.

Conclusions.—1. Excision of the knee should rarely be performed before puberty.

2. Eriasion, arthrectomy, or partial operations are to be preferred.

3. Shortening will usually follow, and depends on the amount of bone removed and the age when the operation was done.

4. Protection should be given the knee for a long time after the operation to prevent flexion, knock-knee, genu recurvatum, bowleg, and other deformities.

5. Always put the leg up straight.

6. In severe, optic cases amputation is preferable to excision.

Mount Sinai Hospital. Dr. Howard L. Lenthal has been appointed attending surgeon to the hospital.

A FURTHER REPORT ON THE USE OF "ANTIPHTHISIC SERUM, T. R." (FISCH), IN TUBERCULOSIS.

By A. MANSFIELD HOLMES, A. M., M. D.,
DENVER, COL.

(Continued from page 409.)

CLASS II. Early-Stage Cases with Bacilli.

CASE I.—Mr. S., aged twenty-three years; nativity, Newfoundland.

Family History.—Tuberculous on mother's side. Mother died of tuberculosis at the age of thirty-nine years; began with hæmorrhages. She tried climates of North Carolina, Florida, and Alpine villages of Switzerland, with no benefit.

Personal History.—Former health good; present trouble began with hæmorrhages September 22, 1897. Had nine severe hæmorrhages within one week; following them, cough, expectoration, and night sweats developed, and temperature rose to 102° F. During three weeks previous to hæmorrhages patient had exercised rather more than usual. As soon as he was able to travel his physician advised him to come to Colorado. He arrived in Denver November 28, 1897; consulted me on the following day.

Physical Condition.—Distinct area of infiltration and dullness over upper lobe of left lung; crepitant râles over entire left lung; also small area of infection in apex of right lung, with râles. Patient had large, well-formed chest, but chest expansion was reduced to an inch and a half. Weight reduced from one hundred and fifty-eight to one hundred and thirty-five pounds; temperature, 99.4° F.; pulse, 102; sputum moderate in amount; bacilli abundant; pronounced dyspnea; strength greatly diminished; appetite and power to sleep impaired; commenced serum at once (November 29, 1897).

First Month.—Slept better; appetite improved; felt stronger; dyspnea diminished; night sweats entirely stopped; sputum frequently tinged with blood. Weight increased to one hundred and forty-two pounds and a half—a gain of seven pounds. Marked improvement in every respect except sputum, which was slightly increased and bacilli abundant; cough loose; temperature reduced; pulse beginning to fall (92–106).

Second Month.—Improvement made during the first month maintained; cough and expectoration beginning to diminish; bacilli remained abundant; temperature close to normal; pulse lower (82–90); once during the month sputum was tinged with blood.

Third Month.—Began increasing dose of serum, hoping to diminish sputum and bacilli. Patient continued to feel well and maintained the gain already made, but very little progress was apparent. Weight increased to one hundred and forty-six pounds—a gain of eleven pounds. Temperature normal; pulse greatly reduced (76–90).

Fourth Month.—Sputum greatly diminished; frequently passed several days without expectoration. March 26th an examination of the sputum was made, and, to my disappointment, it presented almost a solid mass of bacilli. Up to this time I was under the impression that the number of bacilli was a fair criterion of the severity of the tuberculous condition. The serum had been used daily during four months, and I was ex-

pecting a decrease in the number of bacilli, but found them more numerous than at any previous examination. I will frankly confess that I was disappointed and almost at the point of abandoning the serum. I, however, decided to try it for a short time longer, since all other symptoms had improved and the patient was feeling quite well.

Fifth Month.—No material change developed, except intervals of several days frequently passed without cough or expectoration. At the end of fifth month another examination of sputum was made, and I met with another surprise by not being able to find bacilli. Numerous examinations were made, with uniformly negative results; expectoration had almost ceased. In all other respects patient was well. Patient insisted on taking the serum for three months after all signs of the disease had disappeared. At the expiration of this time I gave three tuberculin tests—one, five, and ten milligrammes, respectively—with no evidence of reaction. Patient has been engaged in business six months, and states that his power of endurance is equal to, if not greater than, before the advent of the disease.

I should state that marked improvement continued for several months after discontinuing treatment. It should also be noted that the patient has recently suffered from the gripe, with rapid recovery. Sputum frequently examined for bacilli during and after this attack, with negative results. Present state of health excellent.

CASE II.—Mrs. N., aged thirty years; nativity, Kentucky.

Family History.—Distinctly tuberculous. Brother, sister, mother, and aunt died of tuberculosis.

Personal History.—Present illness began five years ago; gradually lost in weight and strength; general condition failing; weight reduced from one hundred and thirty-seven to one hundred and three pounds; cough and expectoration developed in June, 1897; came to Denver in July, 1897.

Examination, One Month later.—Small area of dullness over upper lobe of left lung; moist râles in apex; right lung normal; appetite and sleeping capacity poor; very weak and easily fatigued; afternoon temperature, 99.5° F.; pulse rapid; cough and morning expectoration; a few bacilli found. Commenced serum August 25, 1897; continued two months.

Close of Treatment.—Gained five pounds; cough and expectoration had ceased and bacilli could not be found; lung had cleared; râles had disappeared; appetite improved; slept better; temperature and pulse normal; pain had left the lungs; patient much stronger. Previous to beginning treatment menstruation had ceased, but appeared after six weeks of serum therapy. Improvement has continued since close of treatment; more than a year has passed and patient has continued in excellent health; is now living in Colorado. She, however, spent several months in her former home in Kentucky the past summer, with no tendency to relapse.

CASE III.—Mr. S., aged twenty-three years; nativity, Ohio.

Family History.—Distinctly tuberculous on both sides.

Personal History.—Telegraph editor; had been working at for one year; during this time his trouble began. Had two hemorrhages in July, 1896; seldom had cough or expectoration; had occasional night sweats. In April, 1897, the cervical glands began to en-

large on left side. Three weeks later the right cervical glands became involved. These rapidly broke down, but were not painful. Had another hemorrhage in August, 1897. Came to Denver October 13, 1897.

Examination, November 26, 1897.—Cervical glands on each side of neck much enlarged, and a number of them discharging; rough breathing over right lung; no râles; morning temperature subnormal; afternoon temperature often one degree above normal; little cough or expectoration; no bacilli found; tuberculin test not made.

Began serum November 30, 1897.

First Month.—Swelling of glands remained stationary; no new glands became involved. At close of second month I removed all enlarged glands. No treatment for one month after operation; no new glands became involved during this month. Resumed treatment again February 1st, and continued three months. During this period only one gland became swollen, and I removed it. Serum continued until May 1, 1898. Left Denver for Michigan six weeks later. Two months after returning east nine glands had enlarged and softened, and were ready for operation. They were removed in University Hospital, Ann Arbor, Michigan.

Returned to Denver November 15, 1898, six months and a half after ceasing treatment. An examination then revealed a slight lesion of the lungs; small amount of sputum, and bacilli found for the first time. The trouble has ceased in the lymphatics, there being no enlarged glands. The active foci of infection have apparently centred in the lungs, but there is very little trouble from this source. Present condition is in every respect better than any time since his trouble began. No serum has been given since May 1, 1898.

CASE IV.—Mr. W., aged twenty-four years; nativity, Iowa.

Family History.—Tuberculous.

Personal History.—Present trouble commenced during 1894 with hemorrhages. Came to Colorado, in 1894, soon after beginning of illness; expected climate to bring about a cure; gained in weight; trouble remained stationary for some time; lung affection then began to increase in severity. During August, 1897, he began to fail; cough and expectoration were increasing; afternoon fever pronounced.

Examination, November 27, 1897.—Upper lobe of right lung involved; coarse and fine râles and some consolidation; profuse expectoration, and bacilli abundant.

Began serum at once, and continued two months; improvement was marked; gained seven pounds and was much stronger; patient experienced an instantaneous reaction which I had previously neglected to explain to him. He became frightened and discontinued the treatment. Ten months have now elapsed and patient has maintained the gain made during the treatment, but has made no further progress.

CASE V.—Mr. H., aged twenty-six years; nativity, Louisiana.

Family History.—Negative.

Personal History.—Druggist; had worked hard from 6 A. M. to 10:30 P. M. during seven years; illness developed in June, 1898; cough had existed over a year. Tuberculosis diagnosed by his physician, and bacilli found June 13, 1898; came to Colorado at once.

Examination made August 7, 1898.—Much of the left lung consolidated; coarse, moist friction râles on forced inspiration; bronchial breathing; cough, sputum,

and bacilli; weight, one hundred and twenty-two pounds; right lung normal; commenced serum August 7, 1898; continued two months and a half.

Close of Treatment.—Sputum increased in quantity and thinner; less cough at night; slight gain in weight; appetite improved; feeling better and stronger; temperature and pulse close to normal, but bacilli more numerous than at any time during the treatment. Patient unexpectedly called home, and was obliged to cease treatment; expected to resume serum again.

CASE VI.—Mrs. P., aged forty-four years; nativity, Kentucky.

Family History.—Tuberculous on mother's side. Mother, aunt, and both maternal grandparents died of tuberculosis.

Personal History.—Illness began in August, 1894, with hæmorrhages; previous health good. Tried climate of North Carolina and Florida, and became worse; came to Colorado in July, 1895. Trouble was apparently held in check without treatment. Returned to Kentucky in May, 1896; came to Colorado again in November, 1896. Trouble returned in February, 1897, when I was consulted.

Examination.—Patient confined to bed; troublesome cough; pains in lungs; distinct dullness over left lung; crepitant râles; temperature, 100° F.; variable pulse. Up to this time there had been little or no sputum and no bacilli found.

Tuberculin Test.—Almost immediately after giving one milligramme "O. T." body began to itch, and a rash appeared, beginning at point of puncture. Within three hours temperature rose to 100.2° F., being one degree higher than on previous day at same hour; headache and pain in lungs.

Began serum February 11, 1898. A few days later I succeeded in obtaining a specimen of sputum; a microscopic examination revealed bacilli. July 6, 1898, patient discontinued serum on account of hot weather and inconvenience in coming for treatment. In many respects patient gained while under the treatment. In others there was no gain. Soon after stopping treatment she began to lose. A few weeks later she had a severe hæmorrhage, and was again confined to her bed. Resumed serum again November 1, 1898.

Result of Treatment (January 1, 1899).—Temperature normal; pulse normal; very little pain in lungs; bacilli continue in sputum; no gain in weight, but patient is feeling better and appetite is good; in every respect improving; treatment continued.

CASE VII.—Mr. C., aged thirty years; nativity, Nebraska.

Family History.—Negative.

Personal History.—Active disease began in June, 1898. There had been some cough during the year previous to this time; rapid loss of strength. Came to Colorado August 18, 1898.

Examination, September 22, 1898.—Extensive consolidation of upper lobe of left lung; occasional râles and impaired vesicular murmur. Cogwheel respiration; nothing abnormal detected in right lung; weight, one hundred and forty-three pounds; pulse, 96.

Commenced serum September 23, 1898. After three months' use of serum the following conditions exist: Weight, one hundred and forty-eight pounds—a gain of five pounds; patient feeling better; less cough; very little sputum; bacilli more abundant; temperature subnormal much of the time; pulse reduced from 98 to 85; left lung clearing; less dullness; râles now heard

where consolidation existed on beginning of treatment; serum continued.

CLASS III. Chronic Cases of Long Standing.

CASE I.—Mr. C., aged twenty-eight years; nativity, Nova Scotia.

Family History.—Tuberculous on father's side.

Personal History.—Attorney at law; health good until February, 1895, when present illness was manifested by hæmorrhages; aphonia became pronounced. Came to Colorado in October, 1895, soon after beginning of illness; gained during a short period; maintained this gain one year, then began to decline. At the end of two years in Colorado disease was steadily progressing. Patient had given up all hope of recovery, but as a last resort decided to test the serum.

Physical Examination, November 1, 1897.—Small cavity in upper lobe of right lung; coarse râles abundant; fine râles in apex of right lung; left lung normal; cough persistent; expectoration profuse; bacilli very numerous; no apparent mixed infection; temperature and pulse close to normal; weight, one hundred and forty-one pounds; normal weight, one hundred and fifty pounds.

Began serum November 3, 1897; continued eight months. Discharged July 3, 1898, with no bacilli in sputum.

First Month.—Cough no less, but easier; expectoration unchanged; appetite much better; tolerated serum well; pain in lungs less; weight at end of first month, one hundred and forty-seven pounds—a gain of six pounds.

Second Month.—Very little progress, but maintained former gain.

Third Month.—Felt better than at any time during previous two years.

Fourth Month.—Maintained gain already made, but remained apparently stationary; slight gain in weight (one hundred and forty-nine pounds); feeling stronger; began to increase dose; tolerated larger doses very well. Patient observed a marked improvement after beginning the use of larger doses.

Fifth Month.—All symptoms improved except cough and expectoration; sputum no less; bacilli abundant.

Sixth Month.—Weight reached one hundred and fifty-five pounds—more than he had ever weighed—a gain of fourteen pounds since beginning the serum.

Seventh Month.—Cough and expectoration decreasing, but bacilli were numerous; patient discouraged. Believing the bacilli would not disappear, we were at the point of discontinuing the use of the serum. There had been almost eight months of daily treatment, and the cough, expectoration, and bacilli continued. I suggested to patient that we discontinue the serum for a time, and he very willingly agreed. On June 28, 1898, I asked for a specimen of the sputum for examination to note the condition at close of treatment. To my surprise, I was unable to find bacilli, although the quantity of sputum was abundant. Numerous examinations gave like results. Serum discontinued July 3, 1898. After the bacilli disappeared the sputum rapidly diminished, and finally ceased. The patient's general condition improved each month, and he has since enjoyed the best health of his life. Weight reached one hundred and fifty-eight pounds—a gain of seventeen pounds since beginning the serum. Physical examination fails to reveal any lung lesion; no bacilli; lung expansion, four

inches. His physical endurance is now greater than ever before.

Later.—This patient has recently suffered from a severe attack of gripe, with two relapses, making a good recovery. The sputum was carefully examined throughout this attack, watching for a return of bacilli, with negative results. This evidently was a severe test in a patient who so recently had well-established tuberculosis, and would seem to be strong evidence of a complete cure.

CASE II.—Mr. C., aged twenty-six years; nativity, Pennsylvania.

Family History.—Distinctly tuberculous on mother's side.

Personal History.—Tuberculosis of seven years' standing; in Colorado four years; has had several slight hæmorrhages; experienced slight improvement after coming to Colorado, but not permanent; took no treatment; failing rapidly; as a last resort he decided to try serum.

Physical Examination on beginning Serum.—Greater portion of right lung involved; cavity and râles in this lung; left lung slightly involved; cough troublesome; expectoration moderate; bacilli abundant; appetite and sleeping capacity poor; lung expansion, two inches and a quarter; temperature close to normal; pulse, 100; marked dyspnea and bronchitis.

Began serum September 23, 1897, and continued its use eight months; gained in strength; appetite improved; slept better, and felt much better; dyspnea less; pulse slower; cough improved; bacilli abundant; lungs felt better.

Patient discontinued the treatment and accepted a position; has been employed during the summer and up to present date. This patient had little to hope for when beginning serum. He has not been cured, but his life has been prolonged at least fifteen months, and his present condition is much better than before beginning the serum.

CASE III.—Mr. W., aged twenty-eight; nativity, Ohio.

Family History.—Negative.

Personal History.—College professor; present illness began July, 1895, with cough, which continued. During the spring of 1896 he began to lose weight and strength. He consulted a number of prominent physicians, and his illness was diagnosed tuberculosis; gave up college work; visited Colorado, New Mexico, and California, with periods of improvement, followed by relapses. The case was referred to me in October, 1898.

Examination.—Right shoulder lower than left; right chest sunken; much infiltration and some consolidation of upper lobe of right lung, with evidence of small cavity; fine crepitant râles also heard over apex and central part of upper lobe of left lung. Lung expansion, two inches and three quarters; weight, one hundred and thirty-two pounds; pronounced dyspnea present; afternoon temperature, 100° F.; pulse, 102; cough troublesome, sputum abundant; bacilli present.

Began serum October 18, 1898. A slow but gradual improvement has been made; patient is stronger and looks better; there is also less dyspnea; cough looser; expectoration slightly increased. In other respects symptoms remain much the same as at beginning of treatment; serum continued.

CASE IV.—Mr. A., aged thirty-six years; nativity, Wisconsin.

Family History.—Tuberculous on father's side.

Personal History.—College professor; former health good; had gripe in January, 1891, and also in January, 1892. Dates the beginning of his present illness from last attack of gripe. First actual tuberculous trouble was recognized in July, 1893. At this time had a constant feeling of disease in his lungs; severe cough and considerable expectoration; marked hoarseness; night sweats; bacilli in sputum; spent several months in pine woods in northern Wisconsin. On returning received lighter work in college; health improved; recovered voice; relapsed in fall of 1895; had pleurisy and acute bronchitis, and also cough and expectoration, but not as bad as during first attack. In December, 1896, lost voice again during four weeks.

In August of 1897 went to Salt Lake City and commenced college work; lost at first, then gained slightly; disease increased rapidly during spring of 1898 until July 1st, when he came to Denver and commenced the serum treatment.

Examination before beginning Serum.—Extensive infiltration and consolidation in right lung, chiefly confined to upper lobe; coarse and fine râles; bronchial breathing; small cavity in upper lobe; left lung normal; former weight, one hundred and fifty pounds; weight when beginning serum, one hundred and twenty-seven pounds. During two months previous to beginning serum treatment the average morning temperature was 99.2° F.; pulse, 94; afternoon temperature, 100° F.; pulse, 94. Lung expansion on beginning serum, two inches and three quarters.

The serum has been judiciously administered since July 1, 1898. Throughout the course of treatment the case of this patient has been exceedingly interesting. There have been no radical or sudden changes, but the improvement has been gradual. The character of the expectoration has changed. At first it was dark green and heavy; it is now thinner in consistence, lighter in color, and increased in quantity. Recently the bacilli are enormously increased. Even with the large quantity of sputum, the microscopic field presents the appearance of being a solid mass of bacilli. Notwithstanding this fact the patient is conscious of a constant improvement. In all other respects, except the cough, expectoration, and bacilli, he is practically well. The cough is looser, skin clearer, and he is stronger and feeling better; pulse slower, and there is less fever. He can now sleep on the back without coughing; lung clearing; less dullness; area of infiltration diminishing; lung expansion increased to three inches; average pulse during the last month, 81; temperature close to normal; weight increased eight pounds.

This has been one of the most valuable cases in my report to show the effects of the serum. I have pushed the serum to its physiological limit, and have frequently been obliged to lower the dose. The ultimate results in this case are being watched with much interest. Treatment continued.

CLASS IV. *Acute Cases with "Mixed Infection."* *

As to the fourth class, I have included cases which develop rapidly and tend toward an early termination, with no tendency to become chronic. This rapid tendency may be explained in two ways: First, on the ground of a feeble resisting power of the patient; second, from the standpoint of a high degree of virulence of the bacilli.

Any close student of tuberculosis will observe severe cases in which sputum and bacilli are very scarce or entirely absent, except at intervals. I have observed examples of this type in which the disease was advanced before expectoration appeared in which bacilli could be found, and then not in abundance. These cases have attracted my attention from the fact that they frequently are of a severe type, and the treatment is slow to yield results. In such cases there is also generally a high temperature.

CASE I.—Miss C.; nativity, Minnesota.

Family History.—Negative.

Personal History.—Occupation, stenographer; had been working very hard in a poorly ventilated office during several years; illness first recognized July 15, 1897. Patient sent to Arizona in fall of 1897; came to Denver in spring of 1898; never had hemorrhages; sputum had never been examined.

Examination revealed advanced pulmonary tuberculosis; left lung extensively involved, with cavity; also beginning disease in right lung; patient very weak; night sweats and morning chills; temperature always high—99°–101.5° F.; pulse, 110–120; respiration, 35–40; hectic flush; profound dyspnoea; dry cough; sputum slight in amount; bacilli abundant.

Began serum May 12, 1898. Continued treatment two months; temperature persistently remained high; pulse rapid and weak; in fact, all symptoms of a high degree of infection were present; patient made no progress; on the contrary, the disease was advancing; treatment stopped and patient returned to her home.

CASE II.—Mr. H., aged forty-two years; nativity, Ohio.

Family History.—Tuberculous.

This case in many respects resembles Case I. The patient was in the last stage of pulmonary tuberculosis when serum was commenced; treatment continued two months with no improvement; serum discontinued; patient returned to his home; lived one month.

CASE III.—Mrs. D., aged thirty-seven years; nativity, Pennsylvania.

Family History.—Very good.

Personal History.—Acute tuberculosis developed in the spring of 1897, traced directly to infection; trouble rapidly advanced; came to Colorado one month after the nature of the trouble was ascertained; tried the climate for a few months; disease advanced; used serum for four months, with no improvement; ceased treatment; patient returned to her home; later results not learned.

CASE IV.—Mrs. M., aged twenty-five years; nativity, Illinois.

Family History.—Tuberculous.

Personal History.—In case developed in July, 1893. Came to Colorado in October, 1891; improved; May 1, 1895, returned to Iowa. At the end of two months trouble rapidly developed; confined to bed one month; August 31, 1895, returned to Denver and remained in Colorado. Health moderate until winter of 1897, when evidence of new invasion appeared.

Examination, March 25, 1898.—Right shoulder lower; right side of chest depressed; dullness over greater portion of right lung; large area of consolidation; evidence of small cavity; apex of left lung also involved; afternoon temperature, 99–100° F.; cough and expectoration, bacilli, occasional night sweats, and loss

in weight and strength; menstruation diminished and irregular during six months. Began serum March, 25, 1897; continued four months.

First Month.—Gained three pounds and a half; cough and expectoration less.

Second Month.—Intervals of several days passed with no expectoration; once during second month sputum was tinged with blood. It should be borne in mind that the patient never had a hemorrhage during the five years and a half of her trouble. About the time of the appearance of the bloody sputum night sweats commenced and temperature was frequently higher. The gain made during first and second months was apparently maintained during third and fourth months, but no further progress observed. At close of fourth month a severe hemorrhage occurred without warning. Four days later another hemorrhage occurred, which terminated fatally.

CASE V.—Mr. N., aged twenty-six years; nativity, Michigan.

Family History.—Tuberculous.

Personal History.—Clerk; pulmonary tuberculosis in last stage when I first saw the case. Patient then confined to bed with temperature 102° F., and pulse 125; chills, night sweats, poor ability to sleep, and loss of appetite. After considerable deliberation I decided to begin the serum treatment.

Began serum treatment November 24, 1897; continued five months.

First month, patient made distinct progress; temperature normal much of the time; night sweats almost stopped; feeling stronger and taking daily walks. Under the serum treatment there was a perceptible gain in all symptoms except the cough and expectoration, the cough being looser and the sputum thinner in consistency; bacilli continued abundant. The case was a difficult one, but distinct evidence of beneficial effects was unquestionably obtained. Eight months have elapsed since close of treatment, and patient is in better condition than any time since coming to Colorado. He has maintained the benefits obtained from the serum, and, although not cured, has suffered no further extension of the disease.

CASE VI.—Mr. C., aged thirty years; nativity, Kentucky.

Family History.—Negative.

Personal History.—Physician; felt well up to one year ago; had been overworking; had hemorrhage and was confined to bed six weeks; came to Colorado four months later.

Examination, March 9, 1898.—Apex of each lung involved; much consolidation of upper lobe of left lung, with cavity forming; sputum abundant; bacilli numerous; temperature, 99.5° F.; pulse, 105; weight reduced from one hundred and forty-five to one hundred and thirty-two pounds; chest expansion, an inch and three quarters.

Began serum March 9, 1898; continued two months; very little improvement; weight diminished; temperature remained high; insomnia continued; suffered from severe reactions; tolerated serum rather poorly; treatment discontinued. Patient has remained apparently stationary to date.

CASE VII.—Mr. R., aged thirty-three years; nativity, Ohio.

Family History.—Tuberculous.

Personal History.—Clerk; active tuberculosis developed in spring of 1898. Patient lost weight and

strength; troublesome dry cough developed without expectoration, accompanied by pains in lungs; obliged to give up work; came to Colorado in April, 1898.

Examination, June 17, 1898.—Small area of consolidation in each lung; no cavity; pronounced daily fluctuations of temperature; morning temperature, 97° F.; afternoon, 101° F.; pulse, 100; troublesome cough; very little expectoration; frequently passed several days without sputum. When sputum was produced, bacilli were abundant.

Serum commenced at once and continued for five months. Very slow, but gradual improvement in all symptoms was observed. Patient was unexpectedly called to his home, and was obliged to discontinue the serum. He, however, has continued to improve, and has resumed the serum under his family physician.

CASE VIII.—Mr. H., aged twenty-six years; nativity, Maryland.

Family History.—One uncle died of tuberculosis.

Personal History.—Occupation, engineer; present illness began in 1894; previous health excellent; came to Colorado in spring of 1895; improved; did not consult a physician until spring of 1897, when disease gave evidence of extending. I first saw the patient early in December, 1897.

Examination.—Both lungs extensively involved; cavity in upper lobe of left lung; marked aphonia; temperature, 100.4° F.; pulse, 100; marked emaciation; weight reduced from one hundred and seventy to one hundred and twenty-five pounds; cough troublesome; expectoration abundant; bacilli very numerous.

Began serum December 14, 1897; continued treatment five months. During four months flattering results were obtained. All functions improved; slight gain in weight; temperature and pulse both approached close to normal, notwithstanding the patient was daily employed; serum tolerated well, even in large doses.

During the fifth month evidence of new infection developed; patient became rapidly worse; returned to his home in June, 1898. His relapse was apparently temporary. The beneficial effects of the serum have continued, but without improvement.

I am thoroughly convinced that if this patient could have gone under such a treatment when he came to Colorado two years and a half before, a recovery would have resulted.

Two important lessons may be learned from this case: First, climate alone is not sufficient. Second, cases too far advanced can not hope for a cure, even with climate and serum. Notwithstanding these facts, it is very evident that the serum frequently prolongs such cases indefinitely.

(To be concluded.)

A POWDER BLOWER FOR THE STOMACH.*

By MAX EINHORN, M.D.

Our deeper knowledge of gastric pathology and the better therapeutic results attained nowadays must be ascribed to the new special methods of diagnosis as well as of treatment of the local conditions of the stomach.

Methods of direct treatment of the affected organ

always merit consideration. Several years ago I devised a spray apparatus for the local application of medications to the mucosa of the stomach. This method has since acquired numerous followers here and abroad. By means of the spray, however, only soluble drugs can be applied, but not substances which are either soluble with great difficulty or not at all. In order to facilitate the introduction of the latter I have devised a powder blower for this purpose. The stomach powder blower* (Fig. 1) consists of an ordinary, not too flexible rubber

FIG. 1.—The stomach powder blower. A, the tubing part; B, connection with the bulb; C, hard rubber end with screw thread for capsule.

FIG. 2.—(Natural size.) The capsule-shaped powder receptacle.

FIG. 3.—The small spoon for putting the powder into the capsule.

tube (.1), twenty-eight inches and a half long, the distal end of which connects by means of a hard-rubber piece with an air-suction bulb (B), the proximate end of which is attached to a hard-rubber piece (C). The latter is hollow and pierced with several small openings at the side for the passage of air, and provided with a screw thread for the capsule. The capsule (D) has numerous holes, and is made in three different sizes (three, three and a half, and four centimetres long),

FIG. 4.—A rubber bag with the string, if desired, with the end of the stomach powder blower.

FIG. 5.—The bag opened, the white spots showing the powder.

(Fig. 2). It is filled with the necessary quantity of powder, by means of a very small spoon (Fig. 3), and screwed on to C.

* Demonstrated at the Society of German Physicians of the City of New York, January 27, 1899.

* The stomach powder blower can be obtained at J. Reindess & Co., 303 Fourth Avenue, New York.

Method.—Insufflation of the stomach with powder can naturally only be done when the organ is empty. It should therefore be performed in the fasting condition, and, in cases in which the stomach is not empty in the morning, after previous lavage. Proceed as follows: According to the quantity of medicament required, one of the capsules, *D*, *E*, or *F*, is filled with the powder and screwed on to the apparatus. The tube is moistened with warm water and inserted into the stomach. The bulb is then compressed three or four times in quick succession. By holding the ear over the gastric region of the patient during insufflation the entrance of air (consequently also of the powder) is distinctly heard. In cases in which there is much mucus in the pharynx and œsophagus its entrance into the holes of the capsule may be prevented by covering them with vaseline in a thin layer. The latter forms a protecting covering and prevents liquids from coming in contact with the powder. When the apparatus is in the stomach and the bulb compressed, the air opens up the vaseline layer over the holes, and the powder can now escape.

The following simple experiment shows that the powder does not collect merely at one spot, but rather spreads over the entire surface of the gastric mucosa:

Take a rubber bag (seven inches long and six inches wide), insert the end of the stomach powder blower filled with powder, and draw the strings together (Fig. 4). Then compress the bulb two or three times and remove the insufflator from the bag. If the latter is now opened, the powder is found equally distributed upon the entire inner surface of the bag (Fig. 5).

This shows that the air disseminates the powder as fine dust over all parts of the inside of the bag. In the stomach the conditions are not different from those in the bag, and the insufflation of the interior of the gastric cavity with the powder will thus be complete.

The correctness of this view can also be proved by the Röntgen rays. The stomach is insufflated with bismuth powder and the patient exposed to the X rays.

FIG. 6. Fluoroscopic picture of the stomach of Miss C., after powdering with bismuth. Pronounced gastropneuxia.

On examining the gastric region with the fluoroscope the entire stomach is visible as a shadowy figure. This can occur only if the bi-muth powder covers the entire inner lining of the stomach.

Dr. Willy Meyer has been so kind as to place at my disposal the use of his excellent X-ray apparatus, and

I take this opportunity to thank him most heartily for his courtesy.

The following drawing is an exact sketch of the stomach of a patient (Miss C.), as it appeared when fluoroscoped after insufflation of bismuth powder (Fig. 6).

The indications for powdering the stomach are manifold: In ulcer ventriculi, bismuth; in gastric hemorrhages, antipyrine; in gastralgia, orthoform; and in erosion, protargol can be directly insufflated. Insufflation of the stomach with bismuth powder appears also to be of great help in X-ray examinations of this organ. The points just mentioned, and others, will have to be carefully investigated in a large number of cases in order to ascertain their real value. At present my intention has been merely to describe this method of powdering the stomach. At some later period I hope to publish the results therewith obtained.

20 EAST SIXTY-THIRD STREET.

HYDROTHERAPY IN CHRONIC DISEASES.*

By SIMON BARUCH, M.D.,

PHYSICIAN TO THE J. BODD WRIGHT MEMORIAL (FORMERLY THE MANHATTAN) GENERAL HOSPITAL, ETC.

DURING the past ten years the methodical application of water in *acute* diseases has received an impetus in this country from which it is hoped there will be no recession.

The movement was inaugurated in this society by a paper on the Cold Bath Treatment of Typhoid Fever, which was read here on February 6, 1889.

Immediately on my return from that meeting I was requested by Dr. Austin Flint to explain to his house staff at Bellevue Hospital the technique of the Brand bath, which he adopted at once.

Since that time it has been warmly espoused by Delafield, Loomis, Peabody, Gilman Thompson, Ball, and Northrup, of New York, J. C. Wilson and Tyson, of Philadelphia, Osler, of Baltimore, and other prominent teachers in these and other cities.

The methodical application of water in *chronic diseases* also received an impulse in this society from a paper read on February 2, 1892, on The Successful Treatment of Chronic Diseases, a Plea for their more Methodical Management.

The utilization of hydrotherapy in chronic diseases was not so rapidly taken up as its use in acute diseases. The reason is plain. Every conscientious physician is guided by his observation at the bedside in forming an estimate of remedial agencies. In acute diseases, like typhoid fever, the patient is visited several times a day or at least once a day, and the treatment is carefully laid down for the guidance of the nurse, who presents a report of all happenings. The behavior of the patient

* Read by invitation before the Medical Society of the State of New York at its ninety third annual meeting.

during and after the bath is closely observed, and a record made of all symptoms. Thus the physician is enabled to watch the effect of hydrotherapy, and if he has ordered it with precision his results assure him of its value.

Chronic cases, on the contrary, are seen once or twice a week, or less frequently, and there is no intelligent supervision and no reliable report, the patient's report being the chief guide to the effect. Moreover, medication is, as a rule, negative and expectant in acute cases, while in chronic cases it is active and positive, iron and other tonics, iodides, malt preparations, hypnotics, and digestive agents being used in combination with hydrotherapy. The result becomes thus uncertain, and deductions with regard to it are unreliable. Moreover, a positive method like that of Brand is usually understood by the physician because he can obtain its details from textbooks, while upon the hydrotherapy of chronic diseases no instruction is given in our schools, and text-books dismiss it with brief references to cold sponging, etc. The physician comes to regard it as an agent of no importance.

It is my aim to impress upon you, as the result of a somewhat extensive observation in private, hospital, and dispensary practice, that we have in the judicious and methodical application of hydrotherapy a remedial agent of pronounced value, an agent whose action is based on a sound rationale, an agent which may be guided with precision, and which may therefore be utilized in the most unpromising cases. That water may claim your earnest attention, it is meet and proper that you be convinced of the rationale of its action.

In the time at my disposal a brief glance at this important point must suffice. If we bear in mind the enormous vascular and nerve terminals of the skin and their intricate connection with the cardiac and cerebro-spinal centres, and if we reflect but a moment on the fact that the latter govern the entire human economy, it at once becomes as clear as day that we hold the key to the situation if we can find an agent which can powerfully affect the blood and nerve supply of the skin. That we possess such an agent in water I do not ask you to accept until you are convinced of its rationale.

Water exerts its action on the skin by its mechanical and thermic action—i. e., as a conveyor of excitation and depression. It is a trite physiological fact that cold contracts smooth muscular tissue and that warmth relaxes it. When cold is applied to the skin, the latter contracts, forming cutis anserina; if the application is prolonged, the cutaneous arterial capillaries are contracted, while the venous are unaffected; the result is the well known cyanotic appearance.

If the application is still more prolonged, necrosis of the tissues, by reason of the deprivation of the vascular supply, is produced; we have frost-bite.

If the application of cold to the skin is brief, the contraction of the arterioles is evanescent and the con-

traction gives way to a tonic dilatation, called reaction, which heightens the vitality of the part.

Similar results are obtained by heat.

Both are cutaneous irritants whose effects are conveyed to the skin through the medium of water in the practice of hydrotherapy.

Water has become popular for this purpose by reason of its great capacity to take up heat and cold and give them off again in the solid, liquid, and gaseous forms. This quality renders it a flexible therapeutic agent which may be applied by various methods to a portion of the body or to its entire surface with varying temperature and pressure and for longer or shorter periods.

Thus we have in the temperature, pressure, and the duration of hydropathic procedures opportunities for utilizing water for various conditions, and so modifying its effects that surprising results may be obtained.

As an illustration let me refer to an ordinary case of syncope from emotional causes. The dash of water on any sensitive surface of the body arouses the patient to consciousness. In a more profound condition, such as opium poisoning, more active procedures, such as a douche or affusion, would be required to produce this effect.

In both instances the rationale is the same: a shock and reactive stimulus to the cutaneous nerve terminals, which is carried on motor tracts to the brain and thence reflected through the pneumogastric nerve to the lungs, deepening respiration, and to the heart, increasing cardiac action.

Upon the utilization of this principle, upon this rationale, is based all the clinical value of external hydrotherapy.

Thermic and mechanical action upon the skin produces positive and readily ascertained effects upon the heart, influencing its action in a positive manner. It can be definitely foretold whether the pulse will be accelerated or slowed, whether it will become more tense or more feeble. Changes in the size of the vessels can also be positively effected; contraction or dilatation by heat or cold, with accompanying increase or diminution of their tone, may also be distinctly anticipated and accomplished. Alterations in the corpuscular elements of the blood itself and in its hæmoglobin have been demonstrated by exact experiments, many of which I have personally conducted. That these results must be far-reaching in many diseased conditions is self-evident.

Since most so-called inflammatory processes have as a pathological basis a disturbed circulatory condition, with changes in the vessel walls and in the corpuscular elements of the blood, and inasmuch as these pathological conditions may be removed by restoring normal circulatory conditions, by hydrotherapy, we have in the latter a remedial agent of great potency in the more common cardiac, circulatory, and vascular diseases.

Physiological experiments, as well as clinical obser-

vation, have positively demonstrated that secretion and excretion, dependent as they are on the circulation, may be enhanced by restoring the latter when disturbed. Hundreds of records have shown that in infectious diseases, like typhoid and pneumonia, for instance, not only is the quantity of urine enormously increased by judicious hydrotherapy, but the urotoxic coefficient is doubled or trebled. The elimination of urea and uric acid, too, has been found by Alois Strasser to be greatly increased in healthy and diseased individuals.

These being well-ascertained facts, the so-called dyscrasic diseases, like gout, rheumatism, diabetes, and syphilis, must be favorably influenced by hydrotherapy.

We have the testimony of that renowned teacher of therapeutics, Professor Semmola, of Naples, that "hydrotherapy excites cutaneous activity and with it all functions affecting tissue change and organic purification, so that frequently real marvels of restoration in severe and desperate cases have been obtained by it."

In a paper read before this society on February 6, 1892, I ventured to state that "in many chronic diseases it has proved so successful after failure of medicinal agents that no case should be yielded up as hopeless until hydrotherapy in some form has been tried."

Seven years have elapsed since this statement was made, and it may be conscientiously reiterated to-day by reason of my observation in numerous cases which have been referred to me by colleagues after disappointment with the best therapeutic methods.

Time does not permit the discussion of the details of technique and methods to be adopted in such cases. A few illustrations must suffice.

A case of chloro-anemia, for instance, which has resisted iron, strychnine, malt, digestives, etc., often assumes a different aspect when the neurovascular discipline produced by the following treatment is secured. In such a case a mild procedure should be adopted.

The room being warm (70° F. or more), the patient should stand in a tub of water at 100° F. and receive rapid ablutions with water at 80° F., small quantities being used in the beginning to avoid chilling.

Friction with a wash rag or bath glove during the ablution aids reaction. The temperature of the water for ablutions should be lowered every day and larger quantities should be applied; the duration should be prolonged also, but decided chilling should always be avoided.

The patient's statement that she feels cold must not be our guide. Chattering of teeth, cyanosis of the nails, and insufficient warming up after the procedure indicate that the reactive capacity of the patient is not adequate.

It is a very common error to increase the temperature of the bath water when the reaction is feeble. Warmer water would *diminish* reactive capacity. Under these conditions the extent of surface treated should rather be diminished. The water should be applied on

the back alone very rapidly and with good friction. The patient should be dried and made to warm up by exercise. The temperature of the bath water may be lowered one degree each day, and the extent of surface proportionately increased. When the patient is able to bear ablutions of 60° F. over the entire body, *affusions* may be substituted with advantage.

A basinful of water at 80° F. may be thrown with some force upon the back for two successive days. Two basinfuls may now be applied and the temperature lowered two degrees. This having been done on two successive days, a basinful on the chest may be added, then two, and so on.

The number of basinfuls may be increased to six, always avoiding chilling. When a temperature of 60° F. is reached by this gradual daily lowering of the bath temperature, the treatment will have produced its legitimate effect. The inspiration is deepened, the pulse is less frequent and more tense, the percentage of hæmoglobin and the number of red cells in the blood drawn from the surface are absolutely increased.

These effects of increased oxygenation may be greatly enhanced by following the treatment with exercise in the open air. The pallid lips assume a brighter hue, the languid eye brightens, the step is lighter, and appetite and assimilation are improved because of the enhanced circulatory conditions in the gastro-intestinal mucous lining.

Another type of cases which I see quite often is in that trying class of neurasthenics who wander from one doctor's office to another, and sooner or later become the prey of charlatans and Christian Science faddists.

These patients present every phase of depreciated vascular and nerve condition. They look wan and worn from loss of appetite and sleep, digestion is impaired, and introspection renders them and all around them miserable.

Such a case has probably once been benefited by treatment, rest cure, change of air and scene, but he returns to his unfavorable environment and gradually but surely all his old symptoms return. He again finds himself tottering on the brink of invalidism; now he believes his reason threatened, his memory weakened; he is the prey of morbid fears; he becomes the despair of family, friends, and physician. What prospect is there for such a case?

I can say from actual observation that if such a patient be subjected to a methodical course of hydrotherapy the result will prove a revelation, provided there is no organic basis for the malady. The mild procedures indicated above may not meet all the indications of this type of cases, although they may be useful as an introduction to more positive treatment.

Douches adapted with regard to temperature, duration, and pleasure to each individual case play the most important rôle here. These are capable of arousing the dormant neurons, enhancing vascular activity, and im-

proving general and local nutrition. The cortical centres, which are the chief points of failure in these depressed neurasthenics, feel the impulse of a better circulation and nutrition. The morbid ideas and illusions vanish. The hypochondriacal introspection ceases, and the patient slowly but surely regains his neurovascular equilibrium. The results of hydrotherapy in such cases are far more enduring than those following other methods in my experience.

Another set of cases which are greatly benefited by hydrotherapy are those unsatisfactory rheumatic, gouty, and lithæmic conditions and adiposity which are the bane of the doctor's life, and which we are often so glad to get rid of by sending the patients to the hot springs. At these resorts many remarkable cures are effected, by removal of the patient from unfavorable environment and by the judicious application of baths and douches under the direction of their skillful physicians. Unhappily, few of our patients are able to leave their homes for this purpose, and for these much may be done by methodical hydrotherapy at home. The course adopted at these springs may be usefully imitated wherever douches under pressure of twenty to thirty pounds can be had. The patient receives a full bath of 100° to 105° F. for five to ten minutes, during which gentle massage is given in the vicinity of the crippled joints. After this he is laid on a warm cot, covered with several blankets, and made to perspire for a specified time. He is then well dried and rested.

The value of this treatment is much enhanced at the springs by alternating or succeeding it with douches over the entire body, except the chest and abdomen, the temperature of the douche water being 101° to 108° F.

These douches should also be followed by rest under warm blankets for a half hour or longer. This treatment stimulates the emunctories, especially when it is combined with the *abundant* and *methodical* drinking of water. Products of retrograde tissue change are eliminated; normal products are formed. Although the patient may lose flesh, his appetite, sleep, and general *bien-aise* are increased, and if the dietary and mode of life are properly regulated his health may be entirely restored. While we can not approach the rapid and decided effects attained by our colleagues at the hot springs, to whom such cases should preferably be referred, great relief may be afforded and even complete restoration may be slowly attained by the hot douche and bath treatment at home.

If there are medicinal agents which are capable of producing similar effects, I have failed to discover them during an active professional life of thirty-seven years. Far be it from me to deprecate the pharmacopœia, but I have arrived at the stage of which that wise therapist, the late Alfred L. Loomis, once said in the Academy of Medicine, "Physicians prescribe less medicine as they grow older." This truth is realized by every con-

scientious practitioner, who becomes convinced by increasing observation of the inadequacy of medicinal remedies when unaided by those hygienic agencies which maintain health and restore it when lost. Among the latter the judicious use of baths has stood preeminent since the days of Hippocrates.

When the simple procedures mentioned above, and which are more fully described in works on hydrotherapy, do not suffice to produce satisfactory results, resort to institution treatment becomes imperative.

Fortunately, there are several institutions in the country where systematic hydrotherapy is administered under medical direction.

My personal experience with hydrotherapy in chronic diseases extends over a period of ten years and embraces over a hundred thousand recorded procedures in neurasthenia, hysteria, some of the psychoses, phthisis, gout, rheumatism, dyspepsia, cardiac diseases, sciatica and other neuralgias, obesity, and neuritis.

The application of this method of treatment to such varied diseased conditions is rendered possible by its flexible nature, which enables us to adapt it by modifications of temperature, pressure, and duration, and numerous technical details to the most varied pathological manifestations, provided the physician has mastered its rationale and mode of action, and its details are not left to the judgment of bath nurses.

My confidence in the value of hydrotherapy in chronic diseases, borne out by actual clinical observation, is confirmed by the most noted clinicians of the present day. The writings of Leyden, Kussmaul, Ziemssen, Erb, Nothnagel, Senator, Charcot, and Krafft-Ebing, and those of Draper in our own country demonstrate that I have not given it undue credit. Indeed, to the marvelous results of hydrotherapy in intractable chronic diseases is due the establishment of numerous institutions in Germany which are run by masseurs, bath nurses, priests, and others. These are unhappily bringing hydrotherapy into the same disrepute which has often been caused by similar espousal in its past history. In New York city also, several institutions of this kind have sprung up under the management of such people, whose knowledge of hydrotherapy is in inverse ratio to their claims. The medical profession may well heed the warning against these pronounced by Brehmer, the father of modern phthisis treatment: "The douche is a dangerous remedy, which should always be given under the supervision of a physician, never by bath nurses alone." And Dr. Draper says: "Its best results require the appointment of a well-ordered establishment, where all the various methods of applying water can be wisely and skillfully directed."

By utilizing only institutions which are under the supervision and direction of a colleague, the physician may obtain all the valuable effects of hydrotherapy for his patients, without subjecting the latter, or himself, to the dangers of its empirical application, which has so

often brought disaster and discredit to this remedial agent.

If water is to occupy a lasting position among remedial agents, a place from which the whims and fancies, the prejudices and passions of coming generations shall not again displace it, it *must remain in the hands of medical men entirely*; its theory and technique must be taught in our schools, and its application demonstrated in our hospitals. The latter is now done in some of the best medical schools of Europe. In Vienna, Professor Winternitz has a clinic and delivers a regular course of lectures on hydrotherapy. In Heidelberg, Professor Vierordt has also established a hydrotherapeutical clinic. In the Berlin University Clinic, Professor Leyden also dwells upon hydrotherapy with much emphasis. The great teacher Kussmaul has recently pointed out the crying need of instruction in this branch of therapeutics. Agitation in favor of making it a regular subject for instruction in our universities has also been begun in the German Parliament. Only by this means will water be rescued from the hands of the quacks and empirics, who thrive upon it to the detriment of the educated practitioner. Witness the crowds of people who fifty years ago flocked to Graefenberg from all parts of the world to be treated with water by the ignorant peasant Priessnitz. Very recently history has repeated itself in the great fame attained by a priest, Father Kneipp, who successfully imitated Priessnitz in the enormous congregation of sick people whom his water cures attracted to Woerishoefen.

Such incidents must lower the medical profession in the estimate of people whose faith in medical learning and skill is rudely shaken by the cures accomplished by a layman after failure of the physician. Is it not clear that if these lay people, who know nothing of the rationale of water and who practise hydrotherapy in the most mechanical fashion, can accomplish so much, the educated physician must achieve far greater results if he has been properly instructed in the technique and rationale of hydrotherapy?

Let me therefore impress upon those of my hearers who are connected with medical schools the need of adding this method of treatment to the practical curriculum.

51 WEST SEVENTIETH STREET.

Therapeutical Notes.

Rhus Aromatica in Nocturnal Incontinence of Urine.—Freyberger (*Treatment; Canada Medical Record*, December) reports a number of cures by means of the fluid extract given in doses of from five to twenty minims, with twice as much aromatic syrup and six times as much distilled water, three times a day. In several instances a temporary aggravation of the trouble,

lasting from four to six days, took place during the first week, but subsided somewhat abruptly.

A Mixture for Dyspepsia.—The following formula is given in the *Riforma medica* for January 25th:

R Pepsin 150 grains;
Hydrochloric acid 15 “
Syrup of bitter-orange peel... 1,800 “
Distilled water, enough to
make 4,500 “

M. S.: A coffeespoonful before dinner and before supper.

A Mixture for Tympanites in Infants.—In the February number of the *Revue mensuelle des maladies de l'enfance* we find the following formula credited to Freyberger:

R Sodium sulphocarbolate.... 4 to 8 grains;
Syrup of bitter-orange peel.... 75 “
Distilled peppermint water.... 375 “

M. S.: A coffeespoonful three times a day for two days.

White of Egg as an Application in Cutaneous Inflammations.—Dr. S. Lewith (*Archiv für Dermatologie und Syphilis*, xliii, p. 441; *Centralblatt für Chirurgie*, March 11th) recommends coating eczematous, erythematous, and other inflamed cutaneous areas with white of egg. It is soothing and slightly compressive, and is readily removed.

Ichthyol in the Treatment of Chronic Bronchitis.—Dr. Le Tanneur (*Bulletin médical*, January 24th; *Indépendance médicale*, March 8th) reports having cured cases of many years' standing with ichthyol given internally in daily amounts of not less than half a drachm. He thinks it should be administered in such a form as to reach the intestine without having been freed in the stomach—namely, in gluten capsules.

A Prescription for Neuralgia.—The March number of the *Centralblatt für die gesammte Therapie* takes the following formula from the *Clinica medica*:

R Extract of cannabis indica..... 7½ grains;
Salicylic acid..... 75 “

M. Divide into five powders. Two or three to be taken daily.

An Antiseptic and Antiphlegmonous Inunction.—The *Centralblatt für die gesammte Therapie* for March attributes the following formula to O. Werler:

R Credé's colloid silver..... 5 parts;
Lanolin 50 “
Vaseline 25 “

M. The skin of one half of the body is to be rubbed with the ointment every twenty or thirty minutes in cases of acute phlegmons and furuncles.

Phosphate of Copper in the Treatment of Tuberculosis and Chlorosis.—*Progrès médical* for March 4th ascribes the following to Luton:

R Neutral acetate of copper..... 1½ grain;
Crystallized phosphate of sodium 3 “
Licorice and glycerin, enough to make one pill.

M. Two such pills to be taken daily.

R Phosphate of copper..... 15 grains;
Pure glycerin, 1 of each..... 37½ “
Distilled water, 1

M.

To be used in hypodermic injections (dose not stated).

Salicylized Gelatin in the Treatment of Eczema.—The *Riforma medica* for February 3d attributes the following formula to Schreimser:

R	Salicylic acid,	{	each.....	10	parts;
	Glycerin,				
	Gelatin,	{	each.....	30	“
	Water,				

The gelatin is to be dissolved with the aid of heat, and the solution applied to the eczematous vesicles.

A Pill for Aortic Palpitation.—The *Riforma medica* for February 10th gives the following formula:

R Quinine hydrobromide 60 grains;
Powdered digitalis, {
Extract of convallaria, { each . . . 45 "

M. Divide into forty pills. From two to four to be taken daily.

A Liniment for Herpetiform Dermatitis.—The *Gazette hebdomadaire de médecine et de chirurgie* for March 9th attributes this formula to Eliot:

R Ammonium sulphiechthyolate, }
Oil of sweet almonds, } ..equal parts.
Limewater, }

M. To be rubbed upon the affected part several times a day.

Formoform.—The *Riforma medica* for March 6th gives the following formula for formoform, which it says is useful for sweating of the feet:

B Formaldehyde	13	parts;
Thymol	10	"
Zinc oxide	3,444	"
Starch	6,627	"

M.

A Paste for the Acne of Young Persons.—The *Riforma medica* for February 25th gives this formula as Veiel's. It differs from a paste that has long been in use chiefly in the substitution of mucilage for glycerin.

B) Mucilage of gum arabic	6 par
Sublimed sulphur,	} each 20 "
Alcohol,	
Water.	

M.

An Injection for Vaginal Gonorrhœa.—The *Progrès médical* for March 11th gives the following as Lutaud's formula:

Alum,	℥ each	150 grains;
Sodium borate,	℥	"
Quinine sulphate	℥	15 "
Carbolic acid,	℥ each	30 drops;
Oil of thyme,	℥	"
Glycerin	℥	6½ ounces.

M. A soup-spoonful, in a quart of hot water, to be injected into the vagina two or three times a day.

Clay as a Dressing.—Langemak (*Münchener medicinische Wochenschrift*, 1899, No. 4; *Gazzetta degli ospedali e delle cliniche*, March 9th) recommends clay as an application to eczematous surfaces and superficial ulcerations, in the form of a paste made according to this formula:

B Clay,	1	each	1	part.
Glycerin,	1
Yinseline	2	parts.

M. The clay is first sterilized by means of heat and then finely powdered.

THE
NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 1, 1899.

THE CARE OF THE SICK POOR IN LARGE CITIES.

THERE is need, we think, of a *juste milieu* between what seems to be desired by the shriekers about the abuse of medical charity, on the one hand, and, on the other hand, the continuance of the present state of things, which is favored by the opposite extremists. Pending the dawn of the millennium, we do not look for any arrangement that will be wholly acceptable to everybody, but we do hope for one that in the main will be acceptable to all reasonable people. A plan that is equitable in its principal features, so far as we can see, has been formulated by a physician who has had several years' experience in New York practice, and we learn that it is that gentleman's purpose to submit it to the legislature, in the form of a bill which he has already drafted, provided he finds that it meets the views of the profession.

Substantially, the features of the project are as follows: The State board of health is to divide cities of the first class into districts of not more than fifty thousand inhabitants. For each of these districts a physician for the poor shall be appointed, after a competitive examination, to hold office for three years, at an annual salary of not less than \$2,500 or more than \$3,000. The bill does not debar him from pursuing his private practice during his incumbency of the office. He must be a legally qualified practitioner who has resided in his district for at least five years, a member of some medical society in good standing, not connected with any dispensary or hospital, and having a recommendation from at least two regular physicians residing in his own district. He is to give his professional services free of charge to the sick poor of his district, to persons injured and requiring immediate medical aid, and to those to whom the police may summon him. To persons who may require or wish to be treated by a specialist in a dispensary or hospital he may issue cards entitling them to free treatment in such an institution, but may refuse cards to persons known to him to be able to pay for the necessary attendance. He is to keep a record of patients treated by him in his official capacity, and make annual reports to the State board of health. Besides doing all these things, he is to act as an exam-

ining physician for the district attorney in cases of sudden death.

It is only a rough draft of the bill that we have seen. We repeat that in the main it commends itself to our judgment, but we recognize that it will have to be modified materially in several of its features, and made more explicit in others, before it will be quite acceptable to either the legislature or the medical profession. For example, it contains a section which forbids the hospitals and dispensaries to treat patients indiscriminately without charge. We presume the institutions that are supported entirely by the public funds are the only ones meant, but it is not so stated; manifestly the State has no power to restrict the benefactions of other hospitals and dispensaries. In the next place, we presume there are many members of the profession who would think it more fitting that the medical officers provided for in the bill should report to the State board of charities than to the State board of health. Further, we should object decidedly to disqualifying a physician because of his holding a hospital or dispensary appointment; in fact, we think a hospital or dispensary physician would, *ceteris paribus*, be better fitted than any other to attend the sick poor. Next, we object to compelling this official to attend in cases of accidents; the police surgeons are already charged with that service, and the bill does not aim to legislate them out of office. Finally, we understand that one of the intents of the bill is to do away with the coroner system. That is a consummation devoutly to be wished for, we admit, but one that probably can not be reached for many years to come, for, as we understand it, the office of coroner can not be abolished without amending the constitution of the State; and, if it could be, why replace the present efficient service of the coroner's office—leaving the system out of account for the moment—by the services of a physician willing to undertake such responsibilities, in addition to attending the poor, for the paltry remuneration of \$2,500 or \$3,000 a year?

The consideration of economy is urged in support of the measure. This seems to us illusory. Not only, as we have said, would there be no doing away, at least for the present, with the great expenses of the coroner's office, but the city health board's corps of summer physicians is not abolished in the bill. Therefore these two expected items of saving would not be realized. Moreover, the author of the bill estimates the expense upon the basis of a division of the city of New York into thirty districts. As a matter of fact, there would have to be seventy or thereabout.

On the other hand, it has been said that the medi-

cal profession of the city is opposed to free attendance upon the poor in their homes. We do not believe that that opposition, if it exists at all, is considerable; certainly it is not intelligible. Which man is in the greater danger of becoming a pauper, he who calls a public physician to attend a member of his family in the family home, or he who makes his first visit to a public resort of paupers, to become by contagion one of their number?

THE CHICAGO HEALTH DEPARTMENT'S MANAGEMENT OF INFECTIOUS DISEASES.

We are indebted to the department for advance sheets of its forthcoming *Bulletin*. They show extraordinary energy and vigilance, coupled with much ingenuity, in dealing with such diseases as diphtheria and scarlet fever, and they account amply for the department's unexampled success in the antitoxine treatment of diphtheria. It seems that whenever a case of sore throat is reported as occurring in a poor family, word is sent by telephone at once, by night as well as by day, to the nearest disengaged medical inspector, who visits the patient immediately. If he finds that the symptoms point to diphtheria, he administers the antitoxine on the spot, without waiting for a bacteriological confirmation of the diagnosis. "The patient, rather than the disease," says the report, "receives the benefit of the doubt." Nevertheless, before leaving, and before the use of any antiseptic or other application to the throat, he inoculates the culture box and smears a microscope slide with mucus from the affected part or places on it a bit of false membrane if there is any. By this means the bacillus may often be identified without the delay required to incubate the specimen.

Stress is laid on the administration of the antitoxine "in full strength and quantity" in every case that warrants the suspicion of diphtheria. Experience has shown that the initial dose should range from two thousand to three thousand units, the former in a bulk of five cubic centimetres, and it is said that the inspectors' maxim has come to be "Inject early and enough." Removing the patient to a hospital is not recommended by the department, and its results abundantly justify it in maintaining that a patient's chances are better if he is kept in his own home, no matter how squalid it may be, than if the delay of transportation to a hospital is incurred. Whenever, for any reason, the removal to a hospital is decided upon, an antitoxine injection is given at once, unless it is forbidden by the family, a common occurrence in the early days of the antitoxine treatment, but a rare one now.

An expedient that is novel, so far as we know, has

been tried by the department to take the place of placarding dwellings in which there is infectious disease. Handbills headed "Warning!" with blanks for the date and the name of the disease, announce that there is such and such a disease in a neighborhood, urge upon parents to find out what family it is that is afflicted, and give information concerning suspicious symptoms. The handbill is printed in English, but the German, Italian, Polish, and Yiddish equivalents of the word warning appear on it in large letters, reliance being had on the curiosity of persons who can not read English to secure a translation. These handbills are distributed in ten or more neighboring houses, given to janitors of apartment houses and especially to children, who are always eager to "spread the news," and affixed to police-patrol boxes, telegraph poles, etc., and to the fences of the nearest school buildings. This experiment is said to promise success. The idea of it is to place the responsibility upon the persons chiefly interested, that is to say, parents.

HERDMAN'S AND BOYCE'S RESEARCHES INTO THE NORMAL AND PATHOLOGICAL HISTOLOGY AND BACTERIOLOGY OF THE OYSTER.

THE supposed connection of the oyster with infective disease prompted Professor Herdman, F. R. S., and Professor Boyce, M. B., to a series of researches which have now been carried on intermittently for a period of three years. The *Proceedings of the Royal Society* for February 16th contain an abstract of their interesting paper which was read before the Royal Society on January 19th.

The "greening" of oysters was fully studied by them, and their opinion is that there are several causes and distinct kinds of greenness in oysters. Of these, some kinds are innocuous, as is the case with the green Marennes oysters so highly prized by epicures, and those of some rivers in Essex on the east coast of England. American oysters rebedded on the English coast, and Falmouth oysters native to England, suffer, however, from noxious forms of greenness; the former, according to the authors, being due to a pale-green "leucocytosis," certainly associated, they say, with a greatly increased amount of copper in the oyster, which mineral is also responsible for the toxic nature of the green Falmouth oyster. On the other hand, the greenness of the Marennes oyster was found not to be due to copper, but to a special pigment which they term "marennum." The green oysters of this latter variety, moreover, are not found to contain any excessive amount of iron over that found in the white varieties; nor do their greener por-

tions—*e. g.*, the gills, palp, etc.—contain more iron than the colorless parts.

On the other hand, the authors find by quantitative analysis that the green American oysters, and also the Falmouth oysters, do contain more copper than the colorless ones, and more proportionately in the greener parts than in those that are less green, and they therefore conclude that this variety of greenness is due to copper. This copper in the American oysters appears to be stored up in noticeable amount in the leucocytes, constituting a "green leucocytosis"; while in the Falmouth oysters it is mechanically attached to the surface of the body in a form insoluble in water, probably a basic carbonate. The feeding of oysters with weak solutions of various copper and iron salts gave negative results.

As to the bacteriology of the oyster, the authors failed to find the *Bacillus typhosus* in any oysters obtained from the sea or from markets. Inoculation with that organism, however, enabled them to recover it from the body of the oyster up to the tenth day.

Sea water appeared to be inimical to the growth of the bacilli, for infected oysters washed in a stream of clean sea water presented a diminution or total disappearance of the microbe in from one to seven days.

The colon group of bacilli is said by the authors to be frequently found in molluscs, especially oysters, sold in towns, but they have no evidence that it occurs in them while living in pure sea water. An anaerobic spore-bearing bacillus possessing the characteristics of the *Bacillus enteritidis sporogenes* of Klein was also found. These researches are valuable as indicating the necessity for a thorough sanitary regulation of oyster beds.

THE AMERICAN MEDICAL ASSOCIATION AND THE PRESIDENT OF THE UNITED STATES.

INASMUCH as the next meeting of the association is to be held in Columbus, the capital of the president's own State, and inasmuch as medico-military matters are likely to be quite prominent at the meeting, we readily fall in with a suggestion we have heard made to the effect that it would be graceful for the association to invite Mr. McKinley to be present.

ARMY EXAMINATIONS AND THE NEW YORK STATE LICENSE.

WE are indebted to the *Buffalo Medical Journal* for an advance proof of an article for its April number in which it is clearly shown that it would be pernicious to exempt from the State examination men who served as medical officers during the war with Spain, which is said to be the purpose of a bill now before the legislature. The specious argument had been advanced that, inasmuch as the army examination was very exacting, those who had passed it should be *ex officio* entitled to the

State license, but our contemporary points out that, while the examination for admission into the medical corps of the regular army is of that character, volunteer medical officers who served during the war were as a rule not subjected to any such rigid tests or in many cases to any at all. We may add that in our opinion exemption for any reason whatever is at variance with the spirit of the law governing the issue of the State license.

THE DANGERS OF ORGANOTHERAPEUTIC REMEDIES.

IN our issue for March 25th we referred to the recommendation by the French Academy of Medicine of the control of the sale of thyroid preparations. According to the *Lancet* for March 11th, it would appear that the Austrian government has already taken this matter up, and has prohibited the sale of organotherapeutic remedies save when prescribed by a practitioner. This action is stated to be due partly to the increasing indiscriminate use of such preparations by the laity, and partly to the fact that the absence of chemical tests for organic remedies renders it difficult to prove whether such preparations really contain the medicaments alleged. There can be no doubt that some precautions are as much needed to control their use as with other dangerous drugs.

A WOMAN DOCTOR OF PHILOSOPHY.

ACCORDING to the *Lancet* for March 11th, Fräulein Neumann has the honor of being the first woman to attain to the degree of doctor of philosophy in the Berlin University, having successfully defended her thesis. Slowly but surely throughout the Old World the women are winning their way to recognition, as they have long ago done in the New.

THE TRANSPORTS GRANT AND SHERMAN.

THE *Army and Navy Journal*, in its issue for March 18th, announces the great satisfaction felt by army officers at the freedom from severe illness of the troops taken to Manila on the *Grant* and *Sherman*. It declares that they are the finest transports ever sent abroad with troops, and no better provision was ever made for the care and comfort of soldiers on a long voyage than on those vessels. It is gratifying to learn this from so well-informed a source.

A PROPOSED MEMORIAL OF PROFESSOR BREISKY.

SHORT as the time is which is to elapse before the 25th of May, the tenth anniversary of Breisky's death, we do not doubt that subscriptions will be received in sufficient amount to provide for the proposed memorial, a medallion portrait or bust of the dead obstetrician, being installed in the Prague Lying-in Hospital. The committee's appeal for such subscriptions appears in the *Centralblatt für Gynäkologie* for March 18th. Contributions may be sent to Dr. Oscar Piering (Prag II., Stadtpark).

AN INGENIOUS PLEXIMETER.

IN the February number of the *Physician and Surgeon* Dr. Emil Amberg describes and figures an invention of his, the ring pleximeter, that seems to us likely to prove very handy for facilitating percussion in the

hands of those who prefer to use a pleximeter. It is made to fit the second joint of the forefinger, and resembles a broad finger ring, save that its dorsal aspect presents a plane surface to receive the tap of the percussing finger. We can see that it would readily adapt itself to the intercostal and other depressions of an emaciated subject.

THE CITY BOARD OF HEALTH AND THE ANTITOXINE TRADE.

AS our readers know, there is a bill before the legislature the object of which is to stop the trade of the city board of health in diphtheria antitoxine, vaccine, etc. The question is entirely one concerning commercial interests, and not, as a number of hospital physicians and surgeons who are now protesting against the enactment of the bill seem to have been led to suppose, one with which any fancied crippling of the board in its legitimate work is connected. Let the board have as large an appropriation as may be necessary for the care of the sick poor, but let it keep its hands out of trade, which is all that the bill demands.

THE HAIRPIN IN MINOR SURGERY.

THERE must be few practitioners of any considerable fertility of resource who have not at times found themselves able to accomplish a good deal by the employment of hairpins. Dr. M. Eberson (*Zeitschrift für Krankenpflege*, 1899, No. 1; *Klinisch-therapeutische Wochenschrift*, March 5th) enumerates some of the uses to which the hairpin may be put, such as for the extraction of small foreign bodies from the nose, etc., for curetting exuberant granulations, for stopping hæmorrhage from a wounded artery, and the like. Various other uses of this omnipresent article will readily occur to a man of ingenuity.

PAPER MONEY AS A VEHICLE OF INFECTION.

THE *Gazzetta degli ospedali e delle cliniche* for February 14th calls attention to the fact that a Brussels bank disinfects its soiled notes, and commends the practice followed by the Bank of England of destroying all of its notes that find their way back to the bank. We think our own government would be taking a step in the right direction if it were to follow such a course, though we are not prepared to maintain that serious infection by means of paper money is a very common occurrence.

THE ANTITOXINE TREATMENT OF DIPHTHERIA.

DR. ALFRED E. HARRIS, medical officer of health for the parish of St. Mary, Islington, London, in his quarterly return for the fourth quarter of 1898, says that the mortality in diphtheria cases has been reduced to twelve per cent. He adds: "To the antitoxine treatment of the latter disease the very considerable reduction which has latterly occurred in its fatality has been generally ascribed." In support of this view he quotes the percentage of fatal cases for the three years 1892 to 1894, inclusive (the pre-antitoxine period), with that from 1895 to 1897, inclusive (the antitoxine period), from two important classes in the Metropolitan Asylums Board's hospitals—viz., the entire case mortality, and the mortality in children under five years of age. He also contrasts the mortality with and without antitoxine

in laryngeal diphtheria, whether operated on or not, and the mortality under like conditions in cases of laryngeal diphtheria where tracheotomy was performed. In the first class of cases a steady reduction had occurred from 30.4 per cent. to 17.6 per cent.; in the second, from 53.5 per cent. to 24.9 per cent.; the third showed a recovery rate of 66.3 per cent. with antitoxine, as against 38 per cent. without; and the fourth, a recovery rate of 56.4 per cent. with antitoxine, as against 29 per cent. without. Surely such figures must carry weight with all unprejudiced persons.

ECZEMA OF THE HANDS.

It is well known that one of the great drawbacks to the successful treatment of eczema of the hands is the frequency with which the hands are washed. Dr. Unna, of Hamburg (*Monatshfte für praktische Dermatologie*, xxvi, 11; *Centralblatt für Chirurgie*, March 11th), recommends that they be thoroughly washed only once in twenty-four hours, at bedtime, and then immediately coated with some fatty substance, especially a pyraloxin ointment. At other times they may be washed with oil.

THE TERM SYCOSIS.

THE most that can be said in favor of retaining this old term—expressive only of an appearance which is not commonly met with in the disease—is that dermatologists know what they mean when they use it. Others, however, do not always understand what is meant, and we think a more suitable name would be dermatitis barbae, as suggested by Dr. Regensburger, of San Francisco, in a very interesting article published in the *Journal of the American Medical Association* for March 11th.

THE OPERATIVE STERILIZATION OF WOMEN.

IN our issue for January 28th we referred in an editorial on The Sterilization of Women to Professor Spinelli's operation for that purpose. Dr. H. Rose (*Centralblatt für Gynäkologie*, 1898, No. 45; *Post-graduate*, March, 1899) describes a measure which, he says, is applicable in abdominal and vaginal celiotomy, seems certain of effect and easy of execution from a technical point of view. It is the wedge-like excision of the tubes from the uterus. Where the Fallopian tube is inserted into the substance of the uterus it is seized and traction made upon it. A small elevation is thus produced at that point; and below the point where the excision is to be made three provisional sutures are placed. Then a wedge-like piece is excised with curved scissors; the rapidly tied sutures, which alone nearly close the wound, are sufficient to stop profuse bleeding. The excised wedge, with the adjacent portion of the tube, is now removed completely and any necroses are interrupted sutures at the uterine site of the wound can be inserted. The only novelty claimed by the author is its possible application in that class of cases in which it is planned to induce sterility without interrupting menstruation or producing an artificial menopause. For in a case of Cæcean section will readily permit of sterilization, insuring the patient against subsequent impregnation and at the same time permitting her to retain the other attributes of mature womanhood. This method should prove to possess all the advantages that are claimed for it, there is hope that at some time the

well-intentioned, but in our judgment ill-advised, crusade against the marriage of unfit persons may be converted into an equally effective but unobjectionable legislation against reproduction by them. In the case of those whom it is considered right to debar for the benefit of the race from reproduction, the outcry about mutilation would be absurd.

SCATTERED LEAVES FROM A PHYSICIAN'S DIARY.

UNDER this title Dr. Albert Abrams, of San Francisco, is giving in the pages of the *Medical Fortnightly* a series of twelve satirical sketches from real life. Those that we have read are both clever and interesting. The third, which is recently finished, is entitled *A Modern Esculapius*, and tells the story of a simple farm youth whose ambition to become a physician is aroused by a former herdsmen acquaintance who has blossomed out into an M. D. and a professor of a bogus diploma mill. The farm youth "qualifies" in due course, only to find that it is one thing to have a diploma and another to earn an honest livelihood by it. The sequel is dramatic, and we have no doubt that such a story has been enacted in real life once, twice, and again. As an instance of Dr. Abrams's epigrammatic writing we quote the following: "The greatest hardship of civilization is to be civilized. The improved condition of man known as civilization is a terrible conflict between reason and intuition, with no legitimate reason for the struggle."

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 25, 1899:

DISEASES.	Week ending Mar. 18		Week ending Mar. 25	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	11	4	8	3
Scarlet fever.....	162	18	155	21
Cerebro-spinal meningitis.....	0	11	0	13
Measles.....	224	11	283	11
Diphtheria.....	171	50	177	25
Croup.....	8	4	4	4
Tuberculosis.....	131	169	178	178
Small pox.....	2	1	0	0
Chicken pox.....	55	0	24	0

The New York Academy of Medicine.—At the next meeting, to be held on Thursday, the 6th inst., in the continuation of the discussion on syphilis, a paper will be read by Dr. Francke H. Bosworth on Syphilis of the Respiratory Passages. In a discussion on malaria, Dr. Theobald Smith, of Howard University, will read a paper entitled *The Researches in the Etiology of the Texas Cattle Fever*, and Dr. Barragans, of Mexico, and Dr. Walter B. Jones will read a paper entitled *The Present State of the Insulation of Texas of Malaria*.

A Hospital-Corps Man Commissioned for Gallantry.—The *Boston Herald* of Saturday, March 19, says that a son of a Sergeant in the 10th Mass. Cavalry, now a private in the 10th Mass. Cavalry, has been promoted to the rank of second lieutenant in the army, his name being recommended by the War Department by President McKinley. Private D. J. O'Connell has been officially commended by General O'Connell for gallant service in action with the Filipinos, and for the wounded.

Marine-Hospital Service Health Reports.—The following cases of small-pox and yellow fever were reported to the supervising surgeon-general of the United States Marine-Hospital Service for the week ending March 25, 1899:

Small pox—United States.

Mobile, Ala.	Mar. 17.	2 cases.	
Los Angeles, Cal.	Mar. 4-11.	10 "	1 death.
Washington, D. C.	Mar. 16-23.	No new cases.	
Jacksonville, Fla.	Mar. 4-18.	1 case.	
Key West, Florida.	Mar. 12.	1 "	
Evansville, Ind.	Mar. 13.	1 "	
Atchison County, Kan.	Mar. 16.	21 cases.	
Independence County, Kan.	Mar. 16.	Reported.

-------------------------	------------	----------------------

The Alumni Association of the New York Hospital held a "snoker" at the hospital, in the administration building, on Monday evening, March 27th. It was the first of a series of such gatherings, two to be held each year, to take the place of the annual dinner. The change seems to promise a more widely spread interest in the association.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 25th ult., the following papers were read: Some Thoughts on Diphtheria, by Dr. I. N. Love; and A Tendo-capsular Advancement Operation, the most Accurate and Dependable Operation for Certain Cases of Squint or Insufficiency of External Eye Muscles, by Dr. F. W. Hilscher.

The Richmond Academy of Medicine and Surgery.—At the last regular meeting, on Tuesday evening, the 28th ult., the subject for the evening was a discussion on Oxaluria and its Clinical Significance, which was opened by Dr. R. F. Williams.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Obstetrics, on Tuesday evening, the 28th ult., Dr. Herman E. Hayd read a paper on Hemorrhages after Labor.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending March 25, 1899:*

FULEMAN, G. F., Assistant Surgeon. Detached from the *Vermont* and ordered to the Washington Naval Hospital.

HERNDON, C. G., Surgeon. Detached from the *Richmond* and ordered to the *Prairie*.

HIBBETT, C. T., Surgeon. Detached from the *San Francisco* and ordered to the *Baltimore*.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 18 to March 25, 1899:*

CAMP, CHARLES D., Acting Assistant Surgeon, will proceed to Chicago, and upon his arrival there will report to the surgeon-general.

HALL, WILLIAM R., Major and Surgeon, will proceed to Camp Meade, Pennsylvania, on official business pertaining to the provision of proper hospital accommodation of a camp to be established there.

HEIZMANN, CHARLES L., Major and Surgeon, is detailed as a member of a board of officers appointed to meet at Fort Sam Houston, Texas, for the examination of such officers as may be ordered before it, to determine their fitness for promotion.

LEE, HENRY H., Acting Assistant Surgeon, will proceed to Willet's Point, New York, for duty.

LYNCH, CHARLES, Captain and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at Fort Sam Houston, Texas, for the examination of such officers as may be ordered before it, to determine their fitness for promotion.

McKINNEY, DAVID T., Acting Assistant Surgeon, is relieved from further duty at Minneapolis and will proceed to New Brighton, Pennsylvania, and upon his arrival there will report to the surgeon-general.

PORTER, ELIAS H., Acting Assistant Surgeon, is relieved from further duty at Albany, Georgia, and will proceed to New York and report to KILBOURNE, HENRY S., Major and Surgeon, for duty.

RAYMOND, HENRY L., Captain and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at Augusta, Georgia, for the examination of such officers as may be ordered before it, to determine their fitness for promotion.

SPALDING, CLARENCE M., Acting Assistant Surgeon, will proceed to Rochester, N. Y., and upon his arrival there will report to the surgeon-general.

THOMAS, JOHN W., Acting Assistant Surgeon, will proceed to New Orleans, and upon his arrival there will report to the surgeon-general.

WALKER, PHILIP G., Captain and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at Augusta, Georgia, for the examination of such officers as may be ordered before it, to determine their fitness for promotion.

WELLS, DANIEL D., Acting Assistant Surgeon, is relieved from further duty in the Department of Santiago, and will proceed to Havana and report to the commanding officer of the hospital ship *Missouri* for duty.

WILCOX, TIMOTHY E., Lieutenant-Colonel and Chief Surgeon, is relieved from duty as chief surgeon, Department of Matanzas, and will proceed to New York for duty, relieving WOODRUFF, EZRA, Major and Surgeon. Major WOODRUFF, on being thus relieved, will rejoin his proper station, Fort Trumbull, Connecticut.

WOOD, HALSEY L., Acting Assistant Surgeon, will report to KILBOURNE, HENRY S., Major and Surgeon, for duty on the United States transport *Ingalls*.

Change of Address.—Dr. F. S. Mandlebaum, to No. 717 Madison Avenue, New York.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending March 23, 1899:*

WILLIAMS, L. L., Passed Assistant Surgeon. To report to Surgeon C. E. BANKS, chairman, Board of Examiners, Washington, D. C., for examination to determine fitness for promotion to the grade of surgeon. March 11, 1899.

MCINTOSH, W. P., Passed Assistant Surgeon. To report to Surgeon C. E. BANKS, chairman, Board of Examiners, Washington, D. C., for examination to determine fitness for promotion to the grade of surgeon. March 11, 1899.

PERRY, J. C., Passed Assistant Surgeon. To assume temporary command of service at Port Townsend, Wash., during absence of Passed Assistant Surgeon C. H. GARDNER. March 14, 1899.

GARDNER, C. H., Passed Assistant Surgeon. To proceed to Seattle, Wash., and assume temporary command of service, relieving Acting Assistant Surgeon J. B. EAGLESON. Upon being relieved by a regular officer of the service, to rejoin station at Port Townsend, Wash. March 14, 1899.

TITOMAS, A. R., Assistant Surgeon. To report to Surgeon G. W. STONER, chairman, Board of Examiners, Stapleton, Staten Island, N. Y., for examination to determine fitness for promotion to the grade of passed assistant surgeon. March 13, 1899.

WICKES, H. W., Assistant Surgeon. To report to Surgeon G. W. STONER, chairman, Board of Examiners, Stapleton, Staten Island, N. Y., for examination to determine fitness for promotion to the grade of passed assistant surgeon. March 13, 1899.

CUMMING, H. S., Assistant Surgeon. To report to Surgeon G. W. STONER, chairman, Board of Examiners, Stapleton, Staten Island, N. Y., for examination to determine fitness for promotion to the grade of passed assistant surgeon. March 13, 1899. Relieved from duty at Washington, D. C., to take effect March 31, 1899, and directed to rejoin station at New York, N. Y. March 13, 1899.

HASTINGS, HILL, Assistant Surgeon. Relieved from duty at Washington, D. C., to take effect March 31, 1899, and directed to proceed to Cleveland, Ohio, and assume temporary command of service. March 13, 1899.

FRICKS, L. D., Assistant Surgeon. Assigned to duty as sanitary inspector on United States transport *Sedgwick*. March 16, 1899.

RICHARDSON, T. F., Assistant Surgeon. To report by letter to Surgeon J. H. WHITE for duty at the Immigration Depot, New York, N. Y. March 19, 1899.

KING, W. W., Assistant Surgeon. To report to medical officer in command, Detroit, Mich., for temporary duty and assignment to quarters. March 19, 1899.

THOMPSON, F. J., Assistant Surgeon. To report to medical officer in command, Stapleton, Staten Island, N. Y., for duty and assignment to quarters. March 19, 1899.

RAMSES, CURT, Assistant Surgeon. To report to medical officer in command, Cape Charles Quarantine, for duty and assignment to quarters. March 19, 1899.

FOSTER, S. B., Acting Assistant Surgeon. Granted leave of absence for twenty days from March 10, 1899. March 11, 1899.

MAGUIRE, E. S., Hospital Steward. Upon being relieved by Hospital Steward C. H. MILLER, to proceed to Evansville, Ind., and report to medical officer in command for duty and assignment to quarters. March 13, 1899.

MILLER, CHARLES, Hospital Steward. Upon being relieved by Hospital Steward G. H. BROCK, to report to medical officer in command, Detroit, Mich., for duty and assignment to quarters. March 13, 1899.

STEARNS, W. L., Hospital Steward. Granted leave of absence for thirty days from April 12, 1899. March 11, 1899.

KOLB, W. W., Hospital Steward. Upon being relieved by Hospital Steward F. H. PECK, to proceed to Norfolk, Va., and report to the medical officer in command for duty. March 13, 1899.

PECK, F. H., Hospital Steward. Upon being relieved by Hospital Steward C. G. CARLTON, to proceed to the Tortugas Quarantine Station and report to the medical officer in command for duty and assignment to quarters. March 15, 1899.

CARLTON, C. G., Hospital Steward. To proceed to Egmont Key Detention Camp and report to the medical officer in command for duty and assignment to quarters. March 15, 1899.

BECK, J. E., Hospital Steward. To report to medical officer in command, New Orleans, La., for duty and assignment to quarters. March 15, 1899.

GODFREY, JOHN. To proceed to Port Huron, Mich., for special temporary duty. March 21, 1899.

MEAD, F. W., Surgeon. Granted leave of absence for ten days from April 1, 1899. March 17, 1899.

BANKS, C. E., Surgeon. Detailed as inspector of unseizable property in the purveying division at Washington, D. C. March 21, 1899.

WILLIAMS, L. L., Passed Assistant Surgeon. Relieved from duty at Washington, D. C., and directed to assume charge of the immigration inspection service at New York, N. Y. March 22, 1899.

CORN, J. O., Passed Assistant Surgeon. To proceed to Savannah, Ga., for special temporary duty. March 22, 1899.

SMITH, A. C., Passed Assistant Surgeon. To proceed to Savannah, Ga., for special temporary duty. March 22, 1899.

EAGER, J. M., Passed Assistant Surgeon. Relieved from duty at Washington, D. C., and directed to proceed to Cleveland, Ohio, and assume temporary command of service. March 22, 1899.

WICKES, H. W., Assistant Surgeon. Granted leave of absence for two days from April 3, 1899. March 21, 1899.

HASTINGS, HILL, Assistant Surgeon. Order of March 13, 1899, to proceed to Cleveland, Ohio, revoked, and directed to proceed to Seattle, Wash., and assume command of service. March 22, 1899.

GRUBBS, S. B., Assistant Surgeon. Detailed as quarantine officer for the port of Cienfuegos, Cuba. March 17, 1899.

VOX EPOWELL, E. H., Assistant Surgeon. To report to medical officer in command, South Atlantic Quarantine Station, for temporary duty. March 18, 1899.

MCADAM, W. R., Assistant Surgeon. To report to med-

ical officer in command, Tortugas Quarantine, for temporary duty. March 19, 1899.

Boards Convened.

Board convened to meet at Washington, D. C., at 11 A. M., March 13, 1899, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon C. E. BANKS, chairman; Surgeon J. H. WHITE, and Passed Assistant Surgeon G. T. VAUGHAN, recorder.

Board convened to meet at Washington, D. C., at 9 o'clock A. M., March 14, 1899, for the examination of officers of the service, to determine their fitness for promotion to the grade of surgeon. Detail for the board: Surgeon C. E. BANKS, chairman; Surgeon J. H. WHITE, and Surgeon P. M. CARRINGTON, recorder. March 10, 1899.

Board convened to meet at the United States Marine Hospital, Stapleton, N. Y., Wednesday, April 5, 1899, for the examination of assistant surgeons of the service, to determine their fitness for promotion. Detail for the board: Surgeon G. W. STONER, chairman; Passed Assistant Surgeon L. L. WILLIAMS, and Passed Assistant Surgeon W. P. MCINTOSH, recorder.

Appointments.

STEWART, OLIVER, of Michigan, appointed acting assistant surgeon for duty at the port of Port Huron, Mich. March 11, 1899.

BECK, JULIUS E., of Ohio, appointed junior hospital steward. March 11, 1899.

Society Meetings for the Coming Week:

MONDAY, *April 3d*: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association (annual); Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society (annual).

TUESDAY, *April 4th*: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Broome (quarterly) and Niagara (quarterly), N. Y.; Essex (annual—Newark), Hudson (Jersey City), and Union (annual—Elizabeth), N. J., County Medical Societies; Androscoggin, Maine, County Medical Association (Lewiston); Chittenden, Vermont, County Medical Society; Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, *April 5th*: South Carolina Medical Association (Harris Lithia Springs, Laurens); New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (New Brighton), N. Y.; Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, *April 6th*: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

FRIDAY, *April 7th*: Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, *April 8th*: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Births, Marriages, and Deaths.

Married.

HILL—EGELSTON.—In Churchville, N. Y., on Wednesday, March 22d, Mr. Baird Z. Hill and Miss Jennie May Egelston, daughter of Dr. Benjamin F. Egelston.

PIERCE—MOREL.—In Coconut Grove, Florida, on Monday, March 20th, Dr. V. Mott Pierce, of Buffalo, and Miss Marion Young Morel.

STEWART—SAUNDERS.—In Wallingford, Vermont, on Monday, March 20th, Dr. William E. Stewart and Miss Anna Saunders.

THORNTON—CURANE.—In Boston, on Tuesday, March 21st, Dr. James Brown Thornton and Miss Catherine Ruth Curane.

Died.

EVANS.—In Cambridge, Massachusetts, on Sunday, March 19th, Dr. David Evans, in the fiftieth year of his age.

LLOYD.—In Poultney, Vermont, on Saturday, March 25th, Dr. William E. Lloyd.

McAULIFFE.—In New York, on Sunday, March 19th, George G. McAuliffe, son of Dr. George B. McAuliffe, in the fifth year of his age.

WILCOX.—In Ticonderoga, N. Y., on Friday, March 24th, Dr. Rollin C. Wilcox.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.*

By ARTHUR N. TAYLOR, LL. B.

XII.

RIGHTS AND LIABILITIES OF THIRD PARTIES.

(Continued from page 422.)

Who has Authority.—It is a general rule of law that one who deals with an agent is bound to know at

* In Article IX, the rule of liability of the mother for necessities furnished the minor child after the father's death is stated more broadly than it should be, for the liability of the mother under such circumstances is not in all respects the same as that of the father. When necessities are furnished by the father's authority to the minor child,

his peril the extent of the agent's authority. This rule should be kept in mind while considering who has and who has not authority to bind his principal.

The president of a railroad company has authority to employ a physician and surgeon to attend its injured employees, and by so doing binds the company to pay for such services.

It is pretty well settled that a general superintendent has the same authority.* In the case of Cincinnati, Indianapolis, St. Louis, and Chicago Railroad Company vs. Davis, the company endeavored to escape liability on the ground that it employed a chief physician and surgeon whose duty it was to employ surgeons to give professional attention to persons injured by its trains. Justice Elliott said: "It would be unreasonable to require a surgeon to give professional assistance to a person injured by the company's trains, and then deny him compensation upon the ground that the superintendent had no authority to employ him because that authority was lodged in a chief surgeon. Nor are we willing to sanction a rule imposing upon the surgeons whose services are requested by the superintendent the duty of making specific inquiry as to the scope of the superintendent's authority. Such a rule would operate harshly in many cases, for, if the surgeon must stop to make inquiries before leaving his home or office, the injured man might perish. Better railroad companies should be held responsible for the acts of such a high officer as a general superintendent, although as between him and his principal that officer may usurp authority that is vested in a subordinate agent, than that a surgeon who obeys the summons of a superintendent should be compelled to go unpaid."†

This is undoubtedly the correct rule, notwithstanding the superior court of the city of New York held in 1853 that the superintendent of the New York and Harlem River Railroad Company would not be presumed to have authority to bind his company to pay for medical services engaged by him as officer of such company. The evidence showed that the superintendent had a general supervisory control over the whole line of the road, everything connected with the running of the road being under his supervision and control, and that he paid money to drivers, conductors, and other persons employed by him as superintendent, but had no direction over the treasury. The court argued from this evidence that it did not appear that the superintendent had authority to arrange and liquidate claims made against the company for damages resulting from the negligence of its agents and servants, and that the power exercised in employing a surgeon to attend one employed by the road was analogous thereto, and was consequently not within the scope of his authority.

As this case was not decided by a court of highest authority in the State, and is in direct conflict with reason and justice, and as well with the courts of all other States which have passed upon the question, it is doubted whether the decision would be regarded

as a proper precedent to follow even in New York State.

The division superintendent also has authority to employ physicians and surgeons on behalf of the company.* The supreme court of Kansas recognizes, however, a distinction between professional services rendered to employees and those rendered to injured passengers upon the request of the division superintendent; while in the former case they uphold the presumption of his authority to bind the company, in the latter they repudiate the doctrine.†

A general agent or general manager of a railroad company, which are judicially defined as being the same, is likewise presumed to have power to procure medical attendance for an employee injured in the service of their company.‡

Any agent, employee, or servant of the company, if properly authorized, and acting in accordance with his instructions, may bind the company for services of a physician or surgeon rendered at his request. Where an inspector of a street-railway company was instructed by the company "to see that those injured were taken somewhere where medical aid could be given," employed a physician to attend a passenger who was injured in getting off the car, the company was held to pay the physician's fee.§ And so, when a physician was employed by an agent or employee of a brewing company to attend an employee who had been injured, and the physician inquired of the agent employing him who would be responsible for his medical attention to the injured employee, the agent replied that he had no authority to bind the company, but he would write to them and let the physician know. On the following day the agent showed the physician a telegram from the company as follows: "Have the negro treated." The physician relied upon the telegram, and the court held that he was justified in his conclusion that the agent was authorized to procure medical services to "have the negro treated."||

For an agreement by a company to pay a physician's fees to be of such a character as to enable the physician rendering services to avail himself of it, such agreement or contract must be made with him direct, either by an officer or agent of the company properly authorized to make such contract.¶

If, for example, a physician is called by one injured in a railroad accident to attend him, the physician's contract is with the patient; and the relation does not change even though the president of the railroad calls upon the patient and tells him to employ any physician or surgeon he chooses and the company will pay the expense.Ⓜ This promise to the patient does not create a privity between the company and the physician. If, however, the promise were made to the physician direct and acted upon by him, the company would be bound to him in the full amount of his fee.

Where a company contracts with a physician to attend an employee who has been injured, and reserves

he is liable for their payment in all cases, but, by the rule most commonly in force, the mother, being the head of the family, is liable for such necessities only when the child has no separate estate which may be subjected to that burden.

Ⓜ *Cannery v. S. P. R. Co.*, 6 Cal. 537.

the right to determine what is a reasonable compensation, the court has held that the physician was bound by such reservation, and would not be permitted to recover a greater amount than that fixed upon as a reasonable compensation and tendered by the company. The reason upon which the court holds the physician to this arbitrary determination of the amount of his fee is that the company is under no legal obligation to supply such medical attendance, and therefore if it does assume such obligation it has the right to impose such conditions as it sees fit.* It is doubtful, however, whether the courts will extend the application of this doctrine, or will apply it to this extent where the employee is injured by reason of the negligence of the company.

It is pertinent to state in passing that a contract by a physician with a railroad company to render professional services to employees of the company, or to those to whom the company is liable for personal injuries, does not bind the physician to render services to persons injured while trespassing on the property of the company.†

Who has not Authority.—It seems well settled that the authority to employ a physician on behalf of the company is not included in the general power and authority vested in the conductor, roadmaster, or station agent by virtue of his office or position.‡ And it makes no difference however positively such employee promises the company will pay, such engagement and promise are wholly outside of the scope of their general authority.⁴ Nor is there any such authority lodged in an engineer.⁵ Nor is the attorney or solicitor of the road presumed to have such authority.⁶

The courts have also held that the employment of a physician or surgeon for the treatment of injured employees does not come ordinarily within the scope of the duties of a general manager of an ordinary manufacturing business,⁷ nor of the manager of a plantation.⁸

In this regard, it will be observed, a distinction is drawn between a railroad company, which is bound by such contracts made by its general manager or general agent, and an ordinary manufacturing business.

Whether or not a physician regularly employed by a railroad company to treat its injured employees has power to bind the company for board and care of such injured employees has several times been considered, and the courts have held that he has no such authority.⁹ In the case of *St. Louis, Arkansas, and Texas Railway Company vs. Hoover*, it was held that the railroad company was under no obligation to refund money advanced by the physician for such board and care rendered to an injured employee.‡

An exception to the rule that a conductor or em-

ployee of the class just considered is unauthorized to employ a physician is found in the humane doctrine of emergency, which is recognized as law by the courts of Indiana, but which has not been followed by the courts of any other States.

This doctrine is based upon the theory that the conductor or employee of highest authority in the immediate locality represents the company, and that in case of a sudden and pressing emergency extraordinary authority and powers arise in him, adequate to the urgent and immediate demands of the occasion.*

This extraordinary power in the conductor or other representative is only coextensive with the duration of the emergency which gives rise to it.† If, therefore, an employee is seriously injured, or injured in such a way that immediate attention should be given him, the conductor or employee of highest authority is empowered to engage the services of a physician and bind the company in so doing. This contract, however, can only be binding upon the company for such services as are immediately and urgently necessary.

In a case where a large number of employees are injured, and there being present only one of the company's surgeons, who is unable to attend all of the wounded, the conductor is authorized to employ another surgeon to amputate the leg of one of the persons injured, and the company is bound to pay for such operation, but not for attention given to such employee after the operation was performed.‡ This doctrine empowering minor agents to bind the company for medical services rendered in case of emergency, it will be remembered, has been recognized as law only by the courts of Indiana. Whether or not this doctrine will gain recognition in other States can not be predicted with certainty, but, as it is founded upon good reasoning and justice, a more extended adoption of the rule may be hoped for.

(To be continued.)

Pith of Current Literature.

The Ætiology of Acute Ulcerative Endocarditis.—Benda (*Riforma medica*, December 13, 1898), in two cases of ulcerative endocarditis, demonstrated to the Society of Internal Medicine of Berlin that in one case the point of entry was the kidney and in the other the tonsil. He combated the opinion of most authors who maintain diphtheroid endocarditis to be a secondary metastatic affection.

The Effect of Infant Vaccination upon Small-pox.—Dr. Alfred Robinson (*Quarterly Medical Journal*, January), in an inaugural address recently delivered before the Sheffield Medico-chirurgical Society, said that in England and Wales the strongest evidence was afforded of the influence of infant vaccination and of its neglect upon the age incidence of small-pox. During the seven years, 1848-'54, the earliest years for which the information was available, of 1,000 deaths from small-pox, 677 occurred among children aged under five

years, while in subsequent groups of five years the proportional number at this age period steadily declined to 193 in the years 1885-89, and afterward rose again to 283 per 1,000 in the five years, 1890-94, concurrently with the decline of infant vaccination.

Unfortunately, he said, no satisfactory official vaccination statistics existed prior to 1872, but it was clear that between 1872 and 1887 the mean percentage of default in infant vaccination fluctuated, but only ranged between 4.3 and 6.4. Since 1887, however, this percentage of default had steadily and rapidly increased to 9.9 in 1889, to 11.3 in 1890, to 13.4 in 1891, to 11.9 in 1892, and to 16.1 in 1893.

It seemed impossible to avoid the connection between vaccination default and this rapid increase of small-pox and the increased incidence of small-pox mortality in young children during the five years, 1890-94, following as it did a steady decline in its proportional incidence during the preceding forty years in which infant vaccination was increasingly practised. Not only had the proportion of deaths from small-pox among children under five to those of all ages declined, but the death-rate of children in this age period from small-pox, which was 1,514 per million in the seven years, 1818 to 1854 (the earliest for which this information was available), had steadily declined in each of the four decennial periods, to fifty per million in 1885-91, or one thirtieth of the rate in the seven years preceding the enactment of compulsory vaccination.

Two Mice in a Child's Intestine.—W. Fritz (*Münchener medicinische Wochenschrift*; *Abeille médicale*; *Revue médicale*, March 8th) says that in attending a child of three years of age for what he diagnosed as intestinal obstruction due to invagination, he administered intestinal irrigations and castor oil. Abundant stools were suddenly evacuated, of fetid odor, in which were found the bodies of two mice, manifestly the cause of the obstruction. Their appearance gave evidence of a protracted stay in the child's intestine. The subsequent stools contained tufts of mouse hair, proving indisputably the passage of the animals through the child's intestinal canal. No explanation of the way in which the mice found their strange habitat is forthcoming.

The Bearing of the Lymphatic Glands on the Modern Doctrine of Infection and Immunity.—Maufred (*Giornale internazionale delle scienze mediche*, November 30, 1898) thus sums up his researches: The lymphatic glands cooperate in the struggle waged by the organism against the bacteria which continually invest and threaten it from the surface of the skin and the mucous membranes, often successfully, by means of a triple function: 1. A filtering action by which they keep the invading bacteria confined in their own tissues, thus preserving the general vitality for a longer or shorter time. 2. An attenuating action upon the same bacteria by which they are killed and then undergo in the adenoid tissue a partial or total loss of their virulence. 3. An immunizing action, resulting from the fact that the organism, under the influence of the two others, attains a state of immunity more or less varied and intense.

The Place of the Pessary in Modern Gynecological Practice.—Dr. J. W. Ballantyne (*Scottish Medical Journal*, March), at a recent meeting of the Edinburgh Obstetrical Society, said that the importance of this subject could not be gauged from the amount de-

voted to it in the society's *Transactions* in the last twenty years, which only amounted to six pages and a half. Inquiry at the various instrument makers showed (1) a steady increase in the number of pessaries sold in the last twenty years; (2) a decrease in the varieties asked for, the most frequent being the ring and Hodge, or their modifications, and occasionally a vaginal stem; (3) a growth in the demand for cures; (4) an almost complete absence of demand for intra-uterine stems.

A study of twenty well-known text-books showed eight strongly in favor of the pessary, five strongly against it, and seven critical of its employment. The advocates of the pessary admit that it has inconveniences, that it must be used with care and intelligence, that it seldom cures, and that it must occasionally give way to operation. Those strongly opposed admit a small residuum of cases where it may or must be used. The chief objections urged against the pessary are: 1. Its *inconvenience*, amounting in some to unpleasantness, giving an unhealthy feeling of dependence on a medical adviser, entailing regular douching, setting up or aggravating a malodorous discharge, interfering possibly with marital relations. 2. *Inefficiency*, in that it rarely cures; some doubting, indeed, if it ever even relieves symptoms, and stating that it may be doing further harm by damaging to a still greater extent the supports of the uterus. 3. Its *injuriosness*. Intra-uterine stems, Zwanck and large ball pessaries have come in for special condemnation, from which the ring and Albert Smith, carefully used in suitable cases, have been generally acquitted. Other writers regard all forms as dangerous, and include among the sequelae to be expected from their use pruritus, vaginitis, ulceration, fistula formation, prevention of union of a torn cervix, subinvolution, cancer, septic inflammation of uterus and tubes, and one writer (Balls Headley) magnifies the inconvenience in marital relations into a danger to morals, saying that the pessary "strikes at the root of the institution of marriage, and especially of monogamy."

The general advantages claimed for the pessary are: 1. *Convenience*—all strong supporters emphasize this. An occasional visit to a gynecologist occupying only a few minutes; frequent vaginal douching, which may be required anyhow; and a transitory feeling of uneasiness in the pelvis when the pessary does not fit exactly or has been worn too long, can not be regarded as sufficient reasons for advising a patient to face the ordeal of a plastic operation with all its inconvenience, expense, and enforced confinement. 2. *Efficiency*. All advocates of the pessary say that it is effective in relieving symptoms, and some maintain that a permanent cure may be effected in some cases in a longer or shorter time. 3. *Safety*. Most gynecologists admit the safety of the ordinary vaginal forms. Others also claim that intra-uterine stems and instruments of the Zwanck type are innocuous; bad results are put down to want of care on the part of the physician or patient.

The opinions of those gynecologists who gave a critical approval to the use of pessaries have been reviewed under the various displacements: (1) *In complete prolapse*, the employment of an Esmarch rubber ring or Hodge Smith, with or without wire bars for cystocele, relieves symptoms, and, in the event of pregnancy occurring, the pessary may be removed in a permanent cure. Most agree that pessaries in these cases have only a palliative effect. (2) *In complete prolapse*, the pessary form of

support is the vaginal stem. The Zwanck and all instruments with screws and hinges are generally regarded as unsatisfactory and dangerous. Even with such forms as the Cutter pessary the relief afforded is precarious. 3. *Antrotractions (sic)*. Most authorities are agreed that vaginal pessaries can do no good here, except possibly when metritis is superadded and the support of a ring might benefit that condition. The use of the intra-uterine stem is condemned by most of these writers as dangerous and tending to sepsis, inflammation, and perforation of the uterus. The stem brought forward by Le-four seems to be the least dangerous—it has no vaginal portion. 4. In *retrotractions (sic)*, these writers are by no means agreed as to the position of the pessary here, and several of them find it necessary to consider the subject under a number of headings. Thus, J. C. Webster divides cases of retroversion into seven classes, and gives special directions for the management of each; these considerations set forth by Webster express the opinions of the majority.

The paper was largely discussed by the members present, most of whom allowed the pessary a large sphere of utility.

Indicanuria.—Dr. William S. Wadsworth (*Proceedings of the Pathological Society of Philadelphia*, March 1st) says that indicanuria may be said to be the occurrence of a substance, or substances, in the urine which may be made to yield a blue color by the application of hydrochloric acid and an oxidizing agent in given proportions. The blue color is occasionally developed spontaneously in the urine upon standing. Cases have been reported in which the color was developed within the body, and it may enter into the composition of vesical calculi.

The chemical considerations, he says, while extremely interesting, do not at this time immediately concern us further than a few general relations. The blue coloring substance is similar to plant indigo, if not the same. It is a produce of the disintegration of nitrogenous bodies. It is related to several other substances, notably indigo-red, that frequently occur in the urine, either with indican or independently.

The chemical theories as to the derivation of this substance through indoxyl sulphate from indoxyl, and this from indol, serve very well till the rather rapidly changing chemical philosophies give us something better.

Urine containing indican may be otherwise normal so far as our present understanding extends. Ordinarily no change of color is observed, though it may be dark, owing to the presence of various substances. The normal constituents vary apparently with complete independence. The sulphates may be increased, though this matter is still far from clear. Albumin and sugar he has found present occasionally. Coloring matter and urates, if in excess, give rise to confusion in estimating the amount of indican unless special precipitants have been used. The presence of bile is also a troublesome feature. The degree of acidity, the specific gravity, the total amount of urine, the odor, the sediment, all appear to vary independently, and, though each has been singled out by one hasty reasoner as of importance in relation to indican, we know of no permanent or fundamental relationship.

Indican occurs in a great variety of diseases and in apparent health. In one hundred cases under treatment at the Pro-Catheter Hospital, taken at random from the

various wards, he found fifty in which indican was present in the urine in varying amounts. The amount varies, as does sugar, with the time of day, activity, taking of food, and the various acts of life. It varies from day to day and over long periods. In twenty cases he repeated the tests at varying intervals and found great variability. In several cases that he had under continual observation he found similar variations. It has been found in cases where the diet was carefully noted, and appears to disregard all dietetic theories. A vegetable diet is asserted to be of special value in reducing indican, yet indican is found in very large amounts in the urine of the horse and of cattle. Milk is supposed by some to reduce it, but one of the first cases published was one of "blue urine" that was cured by discontinuing the use of milk and limewater. Notwithstanding this apparently negative evidence, diet has a decided influence in the individual. Thus, while milk and limewater kept up the condition in the case mentioned, it was a change in diet that did reduce the indican.

Unquestionably certain substances increase the output of indican, just as the amount of sugar in the urine is changed by modifying the diet. In this connection it is most interesting to think how much importance we attach to glycosuria, and how little to indicanuria. Both indicate perverted metabolism; these, with uric acid urine, form an important group. It has been asserted that the acidity of the gastric secretion has a great influence on the amount of indican. While Dr. Wadsworth is not in possession of sufficient clinical data to confirm this, he is strongly inclined to believe that this is a significant factor.

It has been asserted that bone disease is a sure cause, and that fractures always cause indicanuria. Dr. Wadsworth has observed several cases of fracture, both recent and of old standing, and finds rather less indican than usual.

Prolonged suppuration is a favorite text-book cause, yet, he says, and to relate, it appears to have very little influence. He has a number of fracture cases in which there is no increase—in fact, several bad cases gave no indican at all.

Constipation is another imaginary cause that fails to give any increase, even in some of the most persistent gynecological cases. Several other diseases that have been supposed to be peculiarly related to indicanuria appear to be equally unimportant, though the author's experience with them has not been sufficient to warrant a more definite statement.

The temptation to suggest some diseases in which indican is produced is naturally great, and the author yields to it to this extent; he believes it will be found that nervous disorders depending on malnutrition, and those that influence nutrition markedly, have a tendency to indicanuria. His experience has been too limited to establish such a relation, though the cases he has studied strongly suggest it. One caution he must add, however, viz., that it occurs in only certain types of neuro-neritis.

Regarding the physiology and pathology of indican production, he says, our knowledge is far from satisfactory. Briefly outlined, it is somewhat as follows: The food passing through the stomach is acted on by acid and pepsin (proteolysis). It is moved on after a variable period to the intestine. Up to this point we have three factors that may influence the end product: 1. Amount and rate of flow of acid. 2. Muscular activity of stomach. 3. Fermentative processes. In the intestine we have partial or complete neutralization of the

acid and further proteolysis (trypsin), the changes depending again on three factors: 1. The residual reaction of the chyme. 2. The rate of intestinal propulsion (which limits the action of the intestinal juices or allows time for putrefactive process). 3. Chemical influences—proteolysis, putrefaction, fermentation.

This combined chemical activity gives rise to normal products that are easily converted into new substances, on the one hand, for the use of the organism; and on the other, to deleterious substances which may or may not be absorbed. These processes are regulated by the nervous system, and depend on the condition of the tissues of the gut. The whole process varies greatly with the kind, quantity, and condition of the food. Variations in local irritability, in central irritability, and in general nervous tone affect profoundly the secretion of acid, pepsin, and intestinal juices, and produce a wide range of variability in the motor power of the whole tract.

The most plausible theory of the origin of the substances from which indican is produced presupposes a changed proteolysis, and an understanding of the regions, processes, and conditions of normal proteolysis in the digestive tract is the beginning of an understanding of these perverted proteid changes, and we can see how a disturbance of the motor or secretory power of the nerves supplying the tract should modify the normal proteid products that are presented to the absorbing surfaces in the bowel.

We see, he adds, how absurd it is to expect to find one disease that will always give rise to indican. When we realize that the intestinal tract is a chemical laboratory, and that each reaction is conditioned, we see how very unlikely it is that proteolysis will go on normally under all circumstances. We find indican under certain conditions that are not uncommon, yet for which it would be difficult to find a name in the categories of disease. We see that these conditions may arise in health, and that they may not be a part of the diseases in which they exist. Our problem lies in the further study of these conditions, and of the remedial measure that will counteract the tendency to produce that gastro-intestinal equation which permits and promotes perverted proteid change; to determine accurately what gastro-intestinal conditions favor this change and what states of the regulatory nervous mechanism tend to bring about these gastro-intestinal conditions.

first insisted upon descending the stairs. To do this would have been certain death.

Pushing her charge through the window, Miss Troop half carried and supported her down the narrow vertical ladder in safety to the ground, and scarcely had they reached the street when the upper floors collapsed with a crash.

The action speaks for itself, and one can not help admiring the nurse's cool-headed pluck and her profession, which will train a woman to keep her wits about her in such a terrifying emergency, and to think first for her patient. Nor can one help congratulating the individual who has had such an opportunity to be of such signal service to another.

WILLIAM S. THOMAS, M. D.

Book Notices.

The Treatment of Wounds: its Principles and Practice, General and Special. By LEWIS STEPHEN PILCHER, A. M., M. D., Late Passed Assistant Surgeon, United States Navy, etc. With One Hundred and Forty-two Wood Engravings. New York: William Wood & Co., 1899. Pp. xiii+453. [Price, \$3.]

A MODERN and up-to-date work on the treatment of wounds has long been missing from American medical literature, and the appearance of this handsome volume by so distinguished an author is especially welcome. Every page shows the writer's experience and training in the practical points of operative surgery, while the literature, even the most recent, has not been neglected. The book is divided into two sections, one of which is devoted to general principles, bacteriology, inflammation, disinfection of wounds, etc., and a second portion which applies the general principles to wounds of special form or situation. Of the two, the second is perhaps the better. Not that any gross errors are to be detected, but several points mar the perfection of the whole. The antediluvian cuts illustrating the process of repair in wounds and those of the pathogenic bacteria have marred the pages of too many volumes in the past to be allowed a place in any modern work, especially since methods of reproduction have become so perfect and so cheap. The author's regret that pathologists have extended the use of the idea of inflammation to include all the processes taking place in the course of repair is rather misplaced, inasmuch as the process of simple aseptic healing, so called, and the more striking and evident one of healing by second intention, with varied clinical symptoms, are the same when minutely studied, and only differ in the degree with which necrosis or supuration or granulation occurs upon the scene. Too little stress is laid, we think, upon the necessary germ contents of every aseptic wound, and upon the great importance of considering the resistance of the patient to infection. For instance, a child or a healthy adult will stand greater degrees of wound infection without the necessity of primary healing than the debilitated or aged person in whom wound infection may develop at the very first, almost promptly. The "practical" section should know these things, for practical purposes, and rest the recent attempt to change the word "infection" for the necessary infection of wounds with rubber gloves during operation. A word or two and a few

Letters to the Editor.

A NURSE'S HEROISM.

ST. LUKE'S HOSPITAL, NEW YORK, March 18, 1899.

To the Editor of the *New York Medical Journal*:

SIR: The recent fire at the Windsor Hotel affords several examples of heroism, and one particular instance of devotion to duty which furnishes food for reflection to the cynical who believe that doctors and nurses regard their patients as business customers merely.

Miss Troop, a trained nurse, and her crippled patient were on the fifth floor when the fire started. At the time they became aware that the building was burning the corridors were densely filled with people, so that only previous knowledge of the location of the nearest fire escape enabled the nurse to grope her way to it, dragging with her the frightened patient, who

other minor defects, the work is most sound in its principles, and no point of value has been neglected. It is in every way a credit to American scholarship.

The Practitioner's Manual: A Condensed System of Medical Diagnosis and Treatment. By CHARLES WARRENE ALLEN, M. D., Consulting Genito-urinary Surgeon to the City (Charity) Hospital, etc. New York: William Wood & Company, 1899. Pp. ix+851. [Price, \$6.]

THIS imposing volume is intended to assist the discouraged medical man in his search for therapeutic hints, and is therefore arranged alphabetically, with a short description of each disease, to aid in diagnosis. The number of useful formulae is enormous, and we recognize many old and valuable friends. The book is a storehouse of therapeutic facts, and is to be recommended to all such as feel the need of a work for hasty reference.

Handbuch der Therapie innerer Krankheiten in sieben Bänden. Herausgegeben von Dr. F. PENZOLIT, Professor in Erlangen, und Dr. R. STINTZING, Professor in Jena. Zweite theilweise umgearbeitete Auflage. Neunzehnte Lieferung. Mit 13 Abbildungen im Text. Pp. 3 to 320. Zwanzigste (Schluss-) Lieferung. Mit 50 Abbildungen im Text. Pp. 321 to 625. Achtzehnte Lieferung. Mit 16 Abbildungen im Text. Pp. 571 to 862. Jena: Gustav Fischer, 1898.

By reason of the highly specialized character of many of the subjects considered in this concluding section of the *Handbuch der Therapie*, the chapters devoted to them form the least useful portion of this valuable work. For, the necessary limitations of space having precluded the description of methods of treatment with the fullness of detail necessary for a work of reference, or even for a text-book, these chapters possess little interest for either the specialist or the general practitioner. In other respects this portion shows the same admirable qualities frequently remarked in the other parts of the work.

Part XVIII begins with the continuation of the chapter on the treatment of neuralgias and other diseases of the nervous system by Edinger. It is rich in suggestions for the successful management of these sometimes troublesome cases. It is followed by a series of chapters by Stintzing on the treatment of diseases of the spinal cord and its meninges, in which the author insists on the importance of early diagnosis and sanitarium treatment and on the value of regular exercises with special mechanical devices.

Schede contributes an interesting critical discussion of operative procedures for the relief of disease of the nerves and spinal cord.

The chapters on disease of the brain, a considerable part of which is devoted to diagnosis, and a brief chapter on brain surgery are the respective contributions of Henschen and Dahlgren, of Upsala.

A chapter, by Eminghaus, on the general management of the insane, which constitute about one half of the section on mental disease, treats in a comprehensive manner the entire topic in this department of therapeutics. The pre-treatment of the patient of the separate form of insanity, by Ziehen, is, on the other hand, exceedingly meagre.

The chapter on general orthopedics, by von Hei-

neke, and on massage and passive and active exercises, by Ramdohr, are among the least satisfactory of the work. This is due to the small space allotted to these subjects, as it is evidently impossible to describe satisfactorily the treatment of clubfoot, for instance, in one page, or the treatment of flat-foot in twenty lines.

Lenhartz contributes a chapter on the treatment of rheumatism and diseases of muscles, and Hagenbach-Burkhardt and Winckel furnish that on disease of bone.

On the Study of the Hand for Indications of Local and General Disease. By EDWARD BLAKE, M. D. London: Henry J. Glaisher, 1898. Pp. 11 to 53.

THE author of this interesting little volume has endeavored to trace the connection of the changes which take place in the hand in patients suffering with general diseases. The changes in the nail nutrition after or during severe fevers is well illustrated by several drawings. The most marked and valuable indications furnished by the hand are of course those in the rheumatic and gouty conditions and in the nutritional diseases, such as acromegaly and Marie's pulmonary arthropathy, and these are discussed quite fully.

La suture intestinale. Histoire des différents procédés d'entérorraphie. Par FÉLIX TERRIER, Professeur de médecine opératoire à la Faculté de médecine, etc.; et MARCEL BARDOLIN, Préparateur du cours de médecine opératoire à la Faculté, etc. Cours de médecine opératoire. Leçons professées pendant le semestre d'été 1898, à la Faculté de médecine de Paris. Avec 587 figures dans le texte. Paris: Institut de bibliographie scientifique, 1898. Pp. viii+415. [Prix, 15 francs.]

THE authors have endeavored to produce a work of reference in which all the operative procedures for suture of the intestine should be arranged in a chronological order and be made accessible by very complete indices, so that any method or even any illustration may be found and referred to with the least possible waste of time and energy. In this they have succeeded in a very remarkable manner and have made a very valuable contribution to surgical literature. The whole originated in a series of lectures delivered during the summer semester of 1898. The notes of these lectures were taken down and immediately revised and rewritten, the references were verified, the illustrations were added, and the whole was arranged chronologically.

The curious methods employed by the early Hindus are the first to be mentioned, then those of the middle ages, and finally the immense complexities of the modern surgical renaissance. As a mere example of the latter and an instance of the constant repetition which is to be noticed in all operative work where the method of one man is forgotten or unnoticed, and the whole process is, innocently enough, reinvented by another, is the collection of six names attached to the method of support by collapsible rubber bags during the course of the suturing of the intestinal wall. This same thing is to be noticed throughout the whole book, so that the really valuable methods can be enumerated, if not on the fingers of one hand, at least on those of both. Not the least praiseworthy part of the volume is the large number of illustrations in the text, most of them copied by photography from the original articles, so as to guarantee absolute accuracy. The work is an invaluable one for the purpose of reference.

The Phonendoscope and its Practical Application. Lectures delivered by ACRELIO BIANCHI, M. D., of Parma, Professor of Preparatory Clinical Medicine and of Pathology. Translated by A. GEORGE BAKER, A. M., M. D., Physician-in-Chief of the Chinese Medical Dispensary, Philadelphia, etc. With Translations of Special Articles by FÉLIX REGNAULT, M. D., of France, and M. ANASTASIADIS, M. D., of Greece. Philadelphia: George P. Pilling & Son, 1898. Pp. 9 to 77. [Price, 50 cents.]

THESE translations of Bianchi's lectures on the phonendoscope are of value in furnishing the views of the inventor of the instrument and his ideas on the methods of using it. They are well illustrated with a number of diagrams showing the outlines of the internal organs as demonstrated by means of this new device for assisting the ear.

Organothérapie ou opothérapie. Par le Dr. C. HILLEMANT, Ancien interne des hôpitaux de Paris, etc. Paris: G. Steinheil, 1899. [Prix, 0 fr. 75.]

THIS little pamphlet furnishes us with an excellent epitome of the facts which have been discovered concerning the value of the various extracts of the organs of the animal body. The methods of their production and administration are also given.

Leitfaden der Elektrodiagnostik und Electrotherapie. Für Praktiker und Studierende. Von Dr. Tony COHN, Nervenarzt in Berlin. Mit 6 Tafeln und 30 Abbildungen im Text. Mit einem Vorwort von Prof. Dr. E. MENDEL in Berlin. Berlin: S. Karger, 1899. Pp. 139.

THE author of this excellent guide to the therapeutic and diagnostic uses of electricity has endeavored to give within a moderate compass those portions of the subject which are more especially practical and useful to the student and the practitioner of medicine, without burdening the work with theories or making it too abstruse. The accomplishment of this purpose has been much aided by an ingenious series of diagrams of the course of the superficial nerves; while covering these, but not obscuring the outlines, are sheets of transparent paper with the points for the application of the electrodes indicated in red ink. By this means the anatomical value of the drawings is in no way interfered with, and the areas for nerve stimulation are seen at a glance. The whole book shows the hand of the experienced teacher and practitioner.

A Treatise on "Unripe" Cataract. By WILLIAM A. M'KEOWN, M. D., M. Ch., Surgeon to the Ulster Eye, Ear, and Throat Hospital, Belfast, etc. Illustrated by Nine Plates, containing Sixty Original Drawings. London: H. K. Lewis, 1898. Pp. x + 13 to 202. [Price, 12s. 6d.]

THIS book is based entirely upon the author's own personal experience and work, which is a great advantage to the reader in forming an opinion upon the value of the methods of treatment. Fifteen years ago Dr. M'Keown advocated irrigation of the anterior chamber for the removal of lens fragments after cataract extraction. In this book he advocates the removal of "unripe cataracts," aided by this irrigation of the anterior chamber. He considers it much more efficient in removing fragments of cortex than any other method, and

addition it restores the frequent collapse of the cornea. It has also been his personal experience that the necessity of a subsequent capsular operation occurs only in a small percentage of the cases. The author advocates an iridectomy in all cases of cataract extraction. His conclusions are based upon an experience of over seven hundred cases of various kinds, many of the histories of which are given briefly in chapter ix. He believes that he has proved satisfactorily that the introduction within the eye of a sterilized salt solution is harmless, and that irrigation with the fine needle inside the capsule of the lens in incomplete cortical cataract is a safe proceeding. The book is interesting, is honestly written, and will repay careful reading.

Ocular Therapeutics for Physicians and Students. By F. W. MAX OHLEMAN, M. D. (Minden, Germany), Late Assistant Physician in the Ophthalmological Clinical Institute of the Royal Prussian University of Berlin, etc. Translated and edited by CHARLES A. OLIVER, A. M., M. D. (Univ. Pa.), one of the Ophthalmic Surgeons to the Philadelphia Hospital, etc. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xv+9 to 274. [Price, \$1.75.]

THE original edition of this work, in German, appeared in 1896. The American edition is much better fitted for the use of the American student and practitioner. It is well printed on good paper, and has an excellent index with cross references. It is divided into two parts, general and special. The first, or general, part contains five chapters, in which are considered massage, thermic agents, chemical agents, electricity, and general treatment. The second, or special, part is devoted to the therapeutics of the various diseases of the eye. The author has pursued the very wise course of avoiding the advocacy of any special treatment for a given disease, and mentions in full all well-known drugs and methods of treatment which have met the test of experience. More than two hundred different prescriptions are given in full in the metric system, with its equivalent in apothecaries' weights, the latter being an improvement on the German edition, which is the creditable work of Dr. Oliver. The little book will prove a very convenient work to refer to for a change in therapeutics, which is so frequently found necessary in practice.

Die mikroskopischen Untersuchungsmethoden des Auges. Von Dr. S. SIEGMANN, Augenarzt in Hamburg. Berlin: S. Karger, 1899. Pp. xvi+210. [Preis, Mark 6.]

THIS is a monograph devoted to a description of the various methods of preparing the eye for examination and of the various steps in microscopic technique. It is divided into two parts, general and special. The first part contains ten chapters, in which are covered the killing of the animal, the preparation and preservation of the eyeball, the cutting of sections and the mounting of specimens, the examination of the cornea, and the preparation of nerve tissue, muscle, and connective tissue specimens. The second part is devoted to the examination of the different parts of the eye—cornea, sclera, iris, ciliary body, retina, choroid, and lamellae, vitreous, connective tissue, and the optic apparatus, muscles, blood vessels, and the optic nerve. There is also a chapter on the diseases of the eye, and a chapter on the interior of the eye. The book is very interesting but

the work is well printed and will be a great convenience to all who are interested in the preparation of microscopic specimens of the eye for study.

Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A. M., M. D., Professor of Ophthalmology in the Jefferson Medical College, etc. With Two Hundred and Fifty-five Illustrations and Two Chromolithographic Plates. Third Edition, thoroughly revised. Philadelphia: W. B. Saunders, 1899. Pp. 7 to 696. [Price, \$4.]

A THIRD edition within six years speaks well for the success of this work, and it may properly be termed popular. Much new matter has been added, and a great deal of attention has in particular been devoted to the bacteriology of the conjunctiva and cornea, a subject of great interest and importance. Many articles have been largely rewritten. Local anesthesia, with a comparison of the effects of eucaine and holocaine, receives due mention. New paragraphs on favus of the eyelids, schizomycetial infection of the cornea, oyster-shucker's keratitis, and other subjects have been inserted, and the whole work is well abreast with our constantly advancing science. This is one of the best books on ophthalmology published in our language.

Radioscopie et radiographie cliniques. Par le Dr. L. R. RÉGNIER, Chef du laboratoire d'électrothérapie et de radiographie de l'hôpital de la Charité. Avec 11 figures dans le text. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 95.

THE methods of application of the Röntgen rays have been presented in a much more satisfactory way than in the present volume, which contains little that is of value. It is merely one of the many small volumes which follow any new discovery.

BOOKS, ETC., RECEIVED.

Cyclopedia of the Diseases of Children; Medical and Surgical. The Articles Written Especially for the Work by American, British, and Canadian Authors. Volume V. Supplement. Edited by William A. Edwards, M. D., Illustrated. Philadelphia: J. B. Lippincott Company, 1899. Pp. xvi-1332.

International Clinics. A Quarterly of Clinical Lectures on Medicine, Neurology, Surgery, Gynecology, Obstetrics, Ophthalmology, Laryngology, Pharyngology, Rhinology, Otolaryngology, and Dermatology, and Specially Prepared Articles on Treatment and Drugs. By Professors and Lecturers in the Leading Medical Colleges of the United States, Germany, Austria, France, Great Britain, and Canada. Edited by Justin Daland, M. D. (Univ. of Penna.), Philadelphia, Instructor in Clinical Medicine and Lecturer on Physical Diagnosis in the University of Pennsylvania, etc.; J. Mitchell Bruce, M. D., F.R.C.P., London, England, Physician to and Lecturer on the Principles and Practice of Medicine in the Charing Cross Hospital; and David W. Finlay, M. D., F.R.C.P., Aberdeen, Scotland, Professor of the Practice of Medicine in the University of Aberdeen, etc. Volume IV. Eighth Series, 1899. Philadelphia: J. B. Lippincott Company, 1899. Pp. xii 375.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare,

M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Volume I. March, 1899. Surgery of the Head, Neck, and Chest—Diseases of Children—Pathology—Infectious Diseases, including Croupous Pneumonia—Laryngology and Rhinology—Otolaryngology. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. viii-17 to 490.

The Serum Diagnosis of Disease. By Richard C. Cabot, M. D., Physician to Out-patients, Massachusetts General Hospital. New York: William Wood & Co., 1899. Pp. vii-154. [Price, \$1.50.]

Essays for Students. By Stephen Paget, F.R.C.S., Surgeon to the West London Hospital, etc. New York: William Wood & Co., 1899. Pp. 7 to 177.

Respiratory Exercises in the Treatment of Disease. Notably of the Heart, Lungs, Nervous, and Digestive Systems. By Harry Campbell, M. D., B. S. Lond., Fellow of the Royal College of Physicians, London, etc. New York: William Wood & Co., 1899. Pp. viii-200.

A Handbook of Obstetric Nursing for Nurses, Students, and Mothers. Comprising the Course of Instruction in Obstetric Nursing given to the Pupils of the Training School for Nurses connected with the Woman's Hospital of Philadelphia. By Anna M. Fullerton, M. D., Obstetrician, Gynecologist, and Surgeon to the Woman's Hospital of Philadelphia, etc. Fifth Revised Edition, Illustrated. Philadelphia: P. Blakiston, Son, & Co., 1899. Pp. xiv-17 to 262. [Price, \$1.]

Surgical Nursing. By Bertha M. Voswinkel, Late Nurse-in-Charge of the Children's Hospital, Columbus, Ohio. Second Edition, revised and enlarged. With One Hundred and Twelve Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xvi-11 to 206. [Price, \$1.]

Diagnosis by the Urine, or the Practical Examination of Urine, with Special Reference to Diagnosis. By Allard Memminger, M. D., Professor of Chemistry, Urinology, and Hygiene in the Medical College of the State of South Carolina, etc. Second Edition, enlarged and revised. With Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. viii-9 to 124. [Price, \$1.]

Retinoscopy (or Shadow Test) in the Determination of Refraction at One Metre Distance with the Plane Mirror. By James Thorington, M. D., Adjunct Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Third Edition, revised and enlarged. Forty-three Illustrations, Twelve of which are Colored. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xviii-19 to 86. [Price, \$1.]

Twenty-third Annual Report of the Managers and Officers of the New Jersey State Hospital at Morris Plains. For the Year ending October 31, 1898.

Twenty-ninth Report of the Alexian Brothers' Hospital, St. Louis, Missouri.

Report relating to the Registration of Births, Marriages, and Deaths in the Province of Ontario. For the Year ending December 31, 1897.

Miscellany.

The Tri-State Medical Society of Iowa, Illinois, and Missouri.—The seventh annual meeting will be held in Quincy, Illinois, on Tuesday and Wednesday, April 4th and 5th, under the presidency of Dr. C. E. Ruth, of Keokuk, Iowa. The programme includes the following titles: Paroxysmal Tachycardia, by Dr. A. S. Mackey, of Louisiana, Missouri; A Case of Brain Tumor Presenting chiefly Ocular Symptoms, by Dr. James M. Ball, of St. Louis; Glaucoma, by Dr. R. M. Lapsley, of Keokuk, Iowa; Diseases of the Nasal Sinuses and Middle Ear as seen in la grippe, by Dr. F. A. Boucher, of Marshalltown, Iowa; La Grippe, by Dr. O. F. Pile, of Memphis, Missouri; The Treatment of Adenoids and Turbinate Hypertrophies, by Dr. A. E. Prince, of Springfield, Illinois; The Treatment of Endometritis, by Dr. J. C. Murphy, of St. Louis; The Indications and Contraindications for Hysterectomy in Uterine Fibroids, by Dr. M. B. Ward, of Kansas City; The Curative Action of Ergot upon Certain Uterine Myomas, by Dr. Henry T. Byford, of Chicago; Uterine Fibroma, by Dr. F. B. Dorsey, of Keokuk; Uterine Fibroma, by Dr. C. B. Campbell, of St. Joseph, Missouri; Suprapubic Lithotomy, by Dr. J. J. Brownson, of Dubuque; The Treatment of Retroversion of the Uterus, by Dr. F. H. Martin, of Chicago; The Results of Neglected Cases of Cervical Laceration, by Dr. Joseph B. Bacon, of Chicago; Early Surgical Interference per Vaginum in Pelvic Inflammation, by Dr. D. E. Monash, of Des Moines; Some Uses of the Actual Caustic in Gynaecological Therapeutics, by Dr. O. B. Will, of Peoria, Illinois; Abdominal Incision and Suture, by Dr. Francis Reider, of St. Louis; Some Uses of Esmerich's Bandage, by Dr. T. J. Maxwell, of Keokuk; The Latest and Most Successful Treatment of Tetanus, by Dr. E. Lamphar, of St. Louis; Strangulated Hernia: A Successful Operation on a Patient Eighty Years of Age, by Dr. A. W. Williams, of Quincy, Illinois; The Diagnosis of Surgical Diseases of the Kidneys, by Dr. A. H. Cordier, of Kansas City; Movable Kidney, by Dr. Lewis Schouler, of Des Moines; Decapsulation of the Kidney for Special Pathological Conditions, by Dr. A. H. Ferguson, of Chicago; Bone-splitting: A Conservative Measure in the Surgery of the Hand and Foot, with a Report of a Case, by Dr. A. H. Meisenbach, of St. Louis; The Treatment of Fracture of the Thigh, by Dr. Edward Borek, of Rock Bud, Illinois; Esophagotomy, by Dr. C. H. McGee, of Unionville, Missouri; Nerve Exhaustion, by Dr. J. F. Herrick, of Ottumwa, Iowa; Self-intoxication, by Dr. S. K. Davis, of Libertyville, Iowa; The Dietary of Infants, by Dr. F. B. Miller, of Kahoka, Missouri; Professional Perplexities, by Dr. George P. Neal, of Fort Madison, Iowa; The Bacteriology of the Female Genital Tract, by Dr. W. B. LaForce, of Ottumwa, Iowa; Ureic Acid and its Serious Results when not Eliminated, by Dr. M. S. Marey, of Peoria, Illinois; The Status of Typhoid Fe-

ver, by Dr. J. E. Parrish, of Memphis, Missouri; Gangrene from Carbolic Acid, by Dr. H. A. Leipziger, of Burlington, Iowa; The Surgical Treatment of Habitual Criminals, by Dr. A. J. Ochsner, of Chicago; The Application of Cold Water to Allay Persistent Vomiting, by Dr. W. F. Mitchell, of Lancaster, Missouri; Tuberculosis treated with Large Doses of Creosote, by Dr. J. H. Coulter, of Summittsville, Iowa; Misconceptions concerning Locomotor Ataxia, by Dr. John Puntton, of Kansas City; Pneumonia, by Dr. Elmer Lee, of New York; Pneumonia, by Dr. J. T. Lambert, of Farley, Iowa; Pneumectomy: its Possibilities as the Future Treatment of Incipient Pulmonary Tuberculosis, by Dr. John S. Pyle, of Toledo, Ohio; Gallstones, by Dr. D. C. Brookman, of Ottumwa, Iowa; City Mortality Statistics, and what they should Teach Us, by Dr. F. M. Fuller, of Keokuk; Epidemic Cerebro-spinal Meningitis, by Dr. R. C. Berry, of Clermont, Iowa; The Surgery of the Gall Bladder, by Dr. J. R. Hollowbush, of Rock Island, Illinois; Enterorraphy, by Dr. J. L. Skelly, of Pekin, Illinois; Intestinal Constipation and its Etiological Effects, by Dr. H. C. Markham, of Independence, Iowa; Pelvic Reflexes, by Dr. F. B. Robinson, of Chicago; Remarks on Appendicitis, by Dr. J. F. Percy, of Galeburg, Illinois; Puerperal Eclampsia, by Dr. R. B. Turner, of Canton, Missouri; and Melano-sarcoma, with a Report of a Case, by Dr. T. B. Ellis, of Bethany, Missouri.

The Late Dr. Willard A. Heacock.—At a meeting of the Harlem Medical Association held March 13, 1899, it was unanimously

Resolved, That this association has learned with deep regret of the recent death of their co-member, Dr. Willard A. Heacock. His early demise fills us with sorrow, as we are confident that a brilliant future awaited him, because of his assiduous attention to his life work.

Resolved, That these resolutions be spread on the minutes of this association and published in the medical journals, and that a copy be sent to his family.

[Signed.] EMIL MAYER, }
A. C. GOODMAN, } *Committee*
E. J. GRAFF, JR., }

The Late Dr. Frank Archer Bottome.—At a meeting of the Harlem Medical Association, held February 13th, it was unanimously

Resolved, That the members of this association deeply deplore the sudden and untimely death of their fellow-member and co-worker, Dr. Frank Archer Bottome.

Resolved, That we, his associates, express deep regret at the loss of our esteemed colleague and genial friend.

Resolved, That we tender our heartfelt condolence to his family, and be it further

Resolved, That we cause this expression to be sent to the medical journals of this city.

[Signed.] JOSEPH F. LAMBEAU, M. D., }
Chairman,
A. R. CARMAN, M. D., }
MALCOLM M. LEAN, M. D., }

Committee

Exit "Husa." We lately announced that Professor John Uri Lloyd, of Cincinnati, was about to present the results of his examination of "Husa" at a joint meeting of the Cincinnati Society of the American Chemical Society and the Cincinnati Academy of Pharmacy. He did so on March 1st, and he has been kind

enough to send us a copy of his communication. It appears that "husa" is obtainable only in the form of a preparation which is a liquid, for the promoter of this alleged cure for the morphine habit declines to furnish the plant from which it purports to be made, *Viola sagittata*. Professor Lloyd sums up as follows: " *Viola sagittata* is not an eclectic remedy, for the reason that the name does not occur in eclectic literature, and the drug is not employed by eclectics. 'Husa' is said by Dr. Winthrop to be an undetermined plant (unknown to science), found by two plumbe bird hunters and gathered by them by the boat-load. My investigation of 'husa,' as sold by its discoverer to his professional patrons, is to the effect that 'husa' is a liquid containing large amounts of sulphate of morphine, some salicylic acid, some alcohol, water, glycerin, and coloring matter, probably burnt sugar." At the meeting Professor Lloyd demonstrated the accuracy of his statements, which, for that matter, nobody would question. And so it seems settled that "husa" must be set down as a factitious product, along with "gleditschine" and a few other examples of the class.

The Sixth International Otological Congress is to be held in London from August 8th to 12th, under the presidency of Dr. Urban Pritchard. The British organization committee, which numbers over seventy members from Great Britain and the colonies, has Mr. A. E. Cumberbatch for its treasurer and Mr. Crosswell Baber for secretary general. It has also appointed the following subcommittees, viz.: 1. *Reception*, vice-chairman, Mr. Field; honorary secretary, Mr. R. Lake. 2. *Election*, vice-chairman, Dr. Dundas Grant; honorary secretary, Mr. P. Macleod Yearsley. 3. *Dinner*, vice-chairman, Mr. Mark Howell; honorary secretary, Mr. L. A. Lawrence. 4. *Museum*, vice-chairman, Mr. C. A. Ballance; honorary secretary, Mr. Arthur H. Cheate. The president elect is chairman of all the subcommittees.

The meeting will be held at the Examination Hall of the Royal College of Physicians of London and Royal College of Surgeons of England, and the following details have been arranged: On Monday evening, August 7th, a preliminary reception will be held by the president elect. On August 8th, 9th, 10th, and 11th, the congress will be in session, and this will be followed on Saturday, August 12th, by an excursion for members and their lady friends. The official languages of the congress are English, French, German, and Italian.

The subscription, to include a copy of the *Transactions*, is fixed at £1, to be paid to the treasurer, Mr. A. E. Cumberbatch, 80, Portland Place, London, W., before the opening of the congress.

The subject chosen for special discussion is Indications for Opening the Mastoid in Chronic Suppurative Otitis Media, which will be introduced by Professor W. Macewen, of Glasgow, Dr. H. Knap, of New York, Dr. Luc, of Paris, and Professor Poltzer, of Vienna.

A museum of specimens and instruments relating to otology, shown by members, will be held during the meeting. Communications regarding the museum should be addressed to Mr. A. H. Cheate, 117, Harley Street, London, W.

Intending members of the congress are requested to send in their names to the honorary secretary general as soon as possible, and in any case not later than May 1st. Titles of communications, together with a short abstract of the same, should be sent to the honorary secretary general by the same date. According to the regulations

of the congress, no papers shall exceed fifteen minutes in reading; therefore all long communications should be read in abstract.

The German Medical Society of the City of New York.—At the next regular meeting, on Monday, April 3d, Dr. W. Freudenthal will present a case of osteosarcoma of the nose and upper jaw; Dr. H. J. Garrigues will show a specimen of a perfectly preserved urachus in a woman forty-six years old; Dr. A. Rose will read a paper on The Tern Appendicitis and other Unscientific Words of our Nomenclature; and Dr. A. Stein and Dr. Henry J. Wolf will report their experiences in appendicitis.

Erratum in a Therapeutic Note.—A correspondent has kindly called our attention to an evident error in the formula entitled Suppositories for Cystitis, published in our issue for March 11th, on page 341. For "15 grains" each of extract of belladonna and extract of opium, substitute $\frac{1}{2}$ grain, and, since the American extract of belladonna is stronger than most European extracts, the amount of that drug should be still further reduced, to $\frac{1}{4}$ of a grain we should say.

"Music hath Charms," etc.—The *Cincinnati Lancet-Clinic* for February 25th quotes the following from the *Medical Press and Circular*:

A correspondent sends the following festive effusion:

It has been suggested that music might prove a useful adjunct (in some cases, at least) where the usual routine treatment by medicine had not proved satisfactory. I venture to suggest the following well-known airs as being suitable for the cases enumerated, viz.:

Retarded labor from inertia: "Coming through the rye."

Chronic aphonia: "The lost chord."

Melancholia: "The heart bowed down."

Epilepsy: "Let me like a soldier fall."

Cases of chronic deafness: "Come back to Erin."

Pyrexia: "McCoolin."

Cases of doubtful diagnosis: "Oh, dear, what can the matter be?"

We might suggest as additions the following:

Scarlet fever: "The lads in red."

Noises in the ears: "Tarara-boom-de-ay."

Isolation cases: "I'm so lonely."

Illegitimate pregnancy: "I have a silent sorrow here."

Nervous depression: "Cheer, boys, cheer."

Alcoholism versus Opium Using.—Dr. T. J. Happel (*Memphis Lancet*, March), in an article on The Opium Curse, and a Preventive, says that a native Chinese preacher, in comparing the two vices, stated that he found this one striking difference between the effects of the opium vice among his countrymen and those of alcoholic intemperance among Americans: "When the Chinese opium smoker comes home at night he does not abuse his children and kick his wife—his wife kicks him."

"The Clothes they Left Behind Them."—According to the *Western Medical Review* for March 15th, a professor in an Edinburgh college, who was advocating athletic exercises for students, asserted that the youths of Rome used to swim three times across the Tiber before breakfast. One of his listeners laughingly replied: "Then they must have left their clothes on the wrong bank at the end of their swim."

Original Communications.

ERRORS THAT I HAVE MADE IN TWO HUNDRED AND TWENTY-EIGHT CONSECUTIVE CASES DIAGNOSTICATED AS APPENDICITIS.*

By ROBERT T. MORRIS, M. D.

THIS report includes only the cases in which I operated. A number of other suspected cases of appendicitis were seen in consultation during the time covered by the report. These were not operated upon because I eliminated the diagnosis of appendicitis, or awaited the development of more definite evidence. The cases in which a diagnosis of appendicitis was eliminated were chiefly of three sorts. First: So-called lithæmia cases with subacute inflammation of the lymphoid structures of the appendix and cæcum. Second: Cases of neuralgia of the ilio-inguinal and ilio-hypogastric nerves of the right side. Third: Cases of acute colitis, associated usually with intestinal fermentation. These three conditions are readily differentiated from appendicitis by any one who pretends to be expert at palpation. Perhaps I should say expert at abdominal palpation. I have seen many well-trained diagnosticians fail to follow any method of examination which would insure correctness of diagnosis in appendicitis cases. Failures of this sort will become less and less, because diagnosticians who wish to become expert at abdominal palpation will give themselves opportunities for becoming proficient.

The cases in which a diagnosis of appendicitis was deferred were chiefly cases in which palpation did not elicit peculiar testimony. For instance, cases of atypical typhoid fever with ill-defined eruption; cases of renal colic with spasm of abdominal muscles and tenderness of right abdominal viscera on palpation; cases of irritation in the appendix region due to normal involution changes in the appendix. In the latter class of cases the lymphoid layer of the appendix is gradually replaced by connective tissue, and as the connective tissue contracts it makes almost continuous impression upon the crushed nerve filaments. I removed one such appendix, and on that diagnosis, the patient being a physician who was fully competent to decide what he wanted to have done. I have always been opposed, however, to the idea of removing appendices unless they were the seat of definite infective lesions. There are two reasons for my position. First, in the interest of the patient. The death-rate of any surgical operation can not be reduced to zero, and I have always, in speaking and in writing, opposed the idea of disturbing the ap-

pendix unless its tissues were the seat of infective disease at the time of operation. Second, as a matter of personal interest I like to be spared the mortification of an error in diagnosis when the specimen is brought into evidence in the presence of assistants and other spectators. Besides the involution case, there were two other cases in which I thought it best to operate, though the appendices were not infected. These were cases of torsion of the appendix, with inclusion of mucus, and with symptoms of nausea and of local discomfort.

There was only one case in which I found appendicitis where something else was looked for. In an elderly woman, whose case was shown before my class at the college as an example of cancer of the cæcum, I found on operation a chronic abscess dependent upon a perforated appendix and an escaped concretion.

There was one case in which a patient gave a clear history of repeated attacks of appendicitis, but the urgent condition for which I was called to operate was found to be a strangulation of ileum in an adhesion band at the site of the infected appendix. This case was on the border line of error in diagnosis; but in the series of two hundred and twenty-eight consecutive cases in which I operated there were only seven clear errors in diagnosis, as follows:

CASE I. Old Typhoid-fever Complications.—A young woman, thirty years of age, about a year prior to date of operation had been confined to bed for several weeks with an acute abdominal inflammation, diagnosed as typhoid fever with atypical symptoms. After convalescence the patient had periodical attacks of acute inflammation in the right iliac region, and her physician began to feel that he might have mistaken appendicitis for typhoid fever. When I saw the patient a year afterward there was marked tenderness in the appendix region, but adhesions prevented accurate palpation of the appendix. On operation I found a congested appendix free from adhesions. Adhesions about the cæcum and ascending colon were separated, and the appendix was removed. This on microscopical examination proved to be entirely normal. The patient made a good recovery, and was relieved from the serious constipation that had been dependent upon adhesions. The original acute local peritonitis had probably followed the breaking down of a Peyer patch during an attack of typhoid fever.

CASE II. Peritoneal Tuberculosis.—A young woman, twenty-five years of age, had suffered for two years with symptoms of recurrent attacks of appendicitis. I saw her during the subsidence of an acute attack, and on operating found general peritoneal tuberculosis, involving the appendix. The appendix was removed in the belief that it had furnished the focus for tuberculous infection, but on microscopical examination it proved to be normal, excepting that its peritoneal coat was studded with milary tubercles. As a result of operation, the patient recovered from her tuberculous peritonitis.

CASE III. Cancer of Cecum.—A man, thirty-six years of age, had suffered for several months with constant pain and tenderness in the right iliac region, with occasional acute exacerbations of inflammation. On

* Read before the Society of Alumni of Bellevue Hospital, December 7, 1898.

palpation a round, hard mass was discovered in the appendix region. I operated and found a carcinoma of the appendix involving a part of the cæcum. I removed the appendix and cæcum and made lateral anastomosis of bowel. Nearly two years elapsed before recurrence of carcinoma appeared. Within four years I made four resections of bowel, and the patient continued to attend to his business until recently, when general infection of abdominal viscera developed. As a result of this mistake in diagnosis the useful part of the patient's life was apparently prolonged for more than four years.

CASE IV. Adhesion, Congestion of Appendix.—A young woman about thirty-four years of age had occasional attacks of appendicular colic. She had suffered from metritis and salpingitis. On operation the appendix was found to be adherent to the right Fallopian tube, and it was tense with interstitial exudation; but on removal and macroscopical examination the structures of the appendix were found to be evidently normal. Local peritonitis of the right oviduct had extended to involve the peritonæum of the appendix.

CASE V. Hysteria.—A young woman, seventeen years of age, gave a typical history of repeated attacks of appendicitis. She had been seen by a number of physicians in different cities, and all had agreed upon the diagnosis of appendicitis. She was brought to New York on a mattress. On examination I found the abdomen too tense for accurate palpation, but there was strong presumptive evidence of general peritonitis, believed to be tuberculous in character and resulting from infection from an appendix focus. The history of subjective symptoms, as given to me by the patient, was without a flaw in evidence. On operation I found appendix and peritonæum perfectly normal and not inflamed at all. The appendix was not removed. The patient had recovered from all symptoms of peritonitis on the day after operation, but she showed various other hysterical demonstrations before leaving the hospital.

CASE VI. Pneumonia.—A woman, forty-five years of age, was attacked with symptoms of acute peritonitis. Temperature, 105° F.; rigid abdominal muscles. Intense pain and local tenderness in right iliac region. She gave a history of previous lesser attacks of pain in the right inguinal region. On operation it was discovered that the appendix and right oviduct were bound together by adhesions. The appendix on examination was found to be normal. It had been caught in oviduct adhesions at some time previously. On the following day the patient was found to have typical lobar pneumonia. She recovered. I was called to this case by one of the most expert diagnosticians in this city. A few days later he showed me a precisely similar case of lobar pneumonia with abdominal symptoms, in a young man, for whom a correct diagnosis had been made.

CASE VII. Sequela of Measles.—A youth about ten years of age, nearly convalescent from an attack of measles, suddenly developed symptoms of acute peritonitis. Evidence was in favor of appendicitis, and at the time when I saw the patient he was believed to have general suppurative peritonitis. I opened the abdomen and found an apparently normal appendix, which was not removed. The peritoneal cavity was filled with viscid lymph, which escaped in large quantities. The peritonæum was thickened with infiltrates, but was not reddened as in acute infective inflammation. The patient slowly recovered from the peritoneal symptoms, and I

understand that he subsequently suffered in turn with pericardial, pleural, and meningeal exudation.

Apropos of these seven errors of diagnosis in two hundred and twenty-eight consecutive cases in which diagnosis was determined, I should like to inquire what other disease gives us so small an opportunity to go wrong. It seems to me that appendicitis is one of the most readily diagnosed of all diseases. Four of these seven patients were promptly benefited by the operation and none were really harmed, because the methods of operation that I prefer in appendicitis give patients very little to bear from the operation itself.

THE SIGNS OF INHERITED SYPHILIS.*

By ROBERT H. M. DAWBARN, M.D.,

PROFESSOR OF SURGERY IN THE NEW YORK POLYCLINIC SCHOOL AND HOSPITAL;
SURGEON TO THE NEW YORK CITY HOSPITAL.

THE subject of inherited syphilis is one in which the writer has always taken a special interest—beginning with a residence in the Nursery and Child's Hospital some sixteen years ago. The frightful mortality among children of syphilitic parents was reason enough for this interest, as well as the frequency with which it is met in practice by men of all specialties.

Fournier has more carefully than any one else collected the statistics as to mortality the world over, including the histories of more than six hundred inherited cases, and found that only one child in about four survived. The well-known Moscow list of two thousand cases, among whom only about the same small percentage escaped with their lives, must also be mentioned in corroborative evidence.

An immense majority of all these fatal cases died within their first year of life. On the other hand, of forty cases of *acquired* syphilis in the infant, all but one recovered under proper care.

Obviously, a prompt recognition is essential if treatment is to offer any hope to the congenital syphilitic. And it would therefore seem that a good purpose would be subserved in collecting in compact form as thorough a list as may be of clinical signs of real value and import. This I have herein tried to do, and will now present to you for criticism twenty-seven such diagnostic points. Obviously, not all have equal pathognomonic value; and yet not one has been included for which high authority can not be produced.

In our present "symposium" in the academy for the study of syphilis, several prominent men will write upon various phases of the pathology, including Dr. Jacobi, upon that of children. Therefore, and because my time as one of four speakers is necessarily extremely brief, I will to-night only discuss symptoms and diagnostic values, and these in the fewest words and with but a passing comment.

* Read before the New York Academy of Medicine, March 2, 1899.

A chronological order of involvement in this disease, when inherited, is quite wanting. The symptoms must therefore be designated simply as those which usually are early and those of later appearance. It is understood that the inherited type is that under discussion. Consequently, the initial lesion is not herein studied.

Naturally, we begin with an early group.

Quoting the famous Diday, Dr. J. L. Smith says:

1. "Next to the look of *little old men*, the most characteristic sign is *sallow color of the skin or café au lait*." This applies to the newborn. These little ones are very rarely plump. They are wrinkled to a degree that justifies Diday's graphic words. Still, it is not unknown that even a plump baby, when newborn, may shortly prove syphilitic.

2. I next mention a sign rarely alluded to, but given by a few good authorities. It is included at this early point not because of its prominent value, but because it is to be noted at once. This is an *umbilical cord* so extremely thick as to seem swollen, and also apt to be very long; and to be very slow in becoming detached from the navel. This swelling and unusual nutrition of the cord may be due to a partial *endophlebitis obliterans*, occasionally noticed, and involving the umbilical vein.

3. *Pemphigus Syphiliticus*.—The mortality is almost one hundred per cent. As if it were yesterday, I can remember my pride when, as a first-year student, I confined my initial case, twenty-one years ago. The baby was not much to look at, but then it was the outcome of my honest labor, helped somewhat by the mother, to be sure. Imagine, then, my indignation when, upon the third day, I found its buttocks, palms, and soles a mass of blisters! I accused the father, who was acting as nurse, of having carelessly placed his first-born, and mine, upon the stove since my last visit. This he feelingly denied. It did not occur to me to question him in another line. My preceptor, however, enlightened me as to the nature of the case, and advised me to treat the baby for syphilis, *secundum artem*—after which it would die. This I accordingly did, with the result predicted.

The *vesicular* syphilide—much rarer—occurs, as the name implies, in smaller blisters; and is commonly associated with a pustular eruption. Groups of the little vesicles form here and there, closely packed together. It is not so fatal a sign as pemphigus, but nevertheless indicates a severe type of infection.

It is worth noting that, although syphilis is so polymorphous in its skin manifestations, it is only in the early and inherited type that we find bulke or vesicles. Exceptions to this rule are very rare.

4. The *common eruption* in its most frequent early form is an erythema. The macules first appear upon the lower part of the abdomen and about the genitals, as a rule—pinkish early, later coppery in color. The rash is apt to show itself first about three weeks after birth.

Certain English writers allude to "syphilitic penny pieces," as descriptive of the appearance; but "farthing pieces" would be a little more nearly right: for in size, after becoming fully developed, they average that of the baby's finger nails.

Subsequent crops may show any and all syphilides, fully as polymorphous as, and more irregular in development than, acquired syphilis.

We should remember that in only about twenty-five per cent. of the cases of inherited syphilis do we find any eruptions at all.

5. *Condylomata* are often seen early, and at the mucocutaneous junctions, and also where there is chafing and moisture of the skin. The commonest seat is at the anus.

6. "*Snuffles*" is one of the commonest signs—due to coryza syphilitica, or later on, to a true ozæna. Coryza of the newborn is exceedingly suspicious always, say Ashby and Wright.

7. The same pathological changes in the larynx—i. e., mucous patches, ulceration, or later on, gummatous involvement at times, are responsible for the characteristic hoarseness of the crying and of the speaking voice.

8. *Mucous patches* will be found quite often, and may be observed at times upon any of the mucous surfaces capable of inspection—the lips, mouth, anus, nose, larynx.

9. But even in the absence of such patches a *general stomatitis* and *pharyngitis* is an almost constant phenomenon in early cases of congenital syphilis, according to Holt. Ulceration is apt to appear later. A peculiar desquamation of the tongue has been at times noted too.

10. Sometimes there is a diagnostic value even in a negation; and as a distinguishing sign between the congenital and the acquired variety it is a striking fact, mentioned by a number of authors, that general lymph-nodular enlargement of the usual subacute and chronic kind is characteristically absent in the congenital type.

11. *Hæmorrhages*, while infrequent, are diagnostic when present. They may occur either from ulcerated or from apparently sound mucous membranes; or ecchymotic spots may develop, quite without traumatic cause, here and there beneath the skin.

12. Among visceral involvements, Virchow's term, "*a white pneumonia*," is worth remembering; due mainly to a fatty degeneration of the epithelium of the air vesicles. This pneumonia is the type occurring in the stillborn and those dying not long after birth. In older cases there may be an interstitial pneumonia, or else gumma of the lungs.

Of course, the "white pneumonia" is mainly of *post-mortem* diagnostic value. To be sure, it is suspicious to have a baby born with pneumonia disease, or to have this appear very shortly afterward; but the physical signs of the consolidation can not be said to differ from those of pneumonia otherwise induced.

13. *Involvement of the liver* is very frequent in congenital syphilis, and is due to diffuse interstitial hepatitis or to gummata, or occasionally to amyloid degeneration. A distinct enlargement, accompanying other signs, is suspicious. It may, of course, cause ascites, but is not accompanied by jaundice, which fact is interesting.

14. In newborn syphilitics the *spleen* is almost always involved, according to Holt. Gee, however, puts it as being enlarged in at least one half the cases. Whatever the exact proportion, it is plain that distinct enlargement of this viscus has great diagnostic value. Taylor states that, once begun, the growth is rapid—the size of the organ often being quadrupled in two or three weeks. There may, of course, be kidney involvement, too, but not in a way to enable us to differentiate it from nephritis of other source. This is also true of the pancreas.

15. Certain eye troubles are highly diagnostic. Of these, one, almost pathognomonic, is “*ground glass cornea*,” due to interstitial punctate keratitis, and with no tendency to ulceration.

Iritis, chorioiditis, retinitis, optic neuritis may also be found. But the first-named (keratitis) is the one of greatest diagnostic value.

16. Inflammation of the *middle ear*, by itself, can not be considered of much value; but when associated with certain other symptoms it is otherwise. Hutchinson's famous “*triad of symptoms*” are: notched teeth, ground-glass cornea, and otitis media (*Medical Record*, editorial, August 26, 1893). Hutchinson also mentions a suddenly and painlessly occurring deafness as being almost always of this nature, and may lead to deaf-mutism.

17. A rapidly occurring *alopecia* is suspicious of syphilis, and occurs as well in the inherited as the acquired, though by no means always.

18. Among rare signs, though of great value when present, must be mentioned a *painless orchitis*. The testicle may be handled and pressed with impunity.

19. *Neuroses* must not be forgotten, though infrequent and not occurring very early, as a rule. Chorea, epilepsy, hemiplegia, for example. As to epilepsy, Jackson urges that the brothers and sisters of an epileptic child should be most carefully examined (as well as itself) to determine whether syphilis is not the cause.

Regarding paralyses, it is enough to say that as *gumma* develops in the later stages of congenital syphilis, just as it does in the acquired, there may be any and all forms; and suddenly and quietly appearing paralyses should make us think of this disease before any other, as to a cause.

20. I have deferred a discussion of the sundry osseous signs until this point, not because they occur late, all of them, or are unimportant, but in order to study them in a group together. Among the commonest and earliest of all important signs is *osteo-chondritis*, involv-

ing the shafts and epiphyseal junctions of the long bones. Taylor says this is often the only sign; and that at other times its presence decides the syphilitic nature of coexisting lesions. It is usually found at birth or within a month later. The swellings are rather distinctly limited as a rule, and the child suffers when they are handled. Those of rickets are apt to occur much later, and to be more epiphyseal than in the cartilage and shaft. In bad cases there may finally occur separation of the epiphyses, suppurative osteomyelitis, and necrosis.

21. Later in appearance than osteo-chondritis is *syphilitic periostitis*. Perhaps as characteristic a sign as any from this source is the one called “*the nodes of Parrot*,” and described carefully in Moullin's *Surgery*. Here the two halves of the frontal bone and the two parietal bones are so thickened as to form distinct bosses, four in number, and surrounding the anterior fontanelle.

22. *Dactylitis syphilitica* (one variety of “*spina ventosa*”) affects mainly the first phalanges, and differs from the tuberculous variety in this regard, as also the fact that with syphilis as a cause it is apt to be multiple and symmetrical—that is, appearing on both hands.

23. The *finger nails* have sometimes peculiar forms of onychia. It may be ulcerative; but, in particular, there is one characteristic form—“*the claw*.” In this the root of the nail seems pinched transversely, being thus narrowed, and at the same time it thickens until its appearance earns the appellation given.

24. The *temporary teeth* are cut very early, of bad color, and liable to a crumbling decay. The upper central incisors of the milk set suffer first (Erichsen). It is curious how widespread, even to-day, is the belief that it means bad luck to have teeth at birth; and here, upon eminent authority, is a justification for the superstition. Twice in Shakespeare's play of Henry VI is this alluded to. When, in the Tower, King Henry taunts the hump-backed Duke of Gloster with being born with teeth, the latter considers it sufficient cause for stabbing him to death, which was in those days considered a witty repartee, as it was certainly an effective one.

25. *Hutchinson's Teeth*.—These famous signs are only found in the permanent set, it must be remembered. The upper central incisors are again the ones mainly involved, or at least most characteristic. The notching of their lower edge, and peg shape, or screw-driver shape, are familiar to all medical men. But not all cases of syphilis, either inherited or acquired, who reach the necessary age to have second incisors present Hutchinson's teeth. He has himself pointed out that it is found only in those who have had syphilitic stomatitis at an early age.

26. In late cases are found irregularities, hypertrophies, and asymmetries of bony development. In the face the *nose* is the characteristic deformity. This, due to necrosis, has shortened—the lower part retreating

toward the upper part; or else the bridge is sunken. (A most ill-omened sign, for when the bridge is quite gone, of course they can never get over it.)

The *tibia* is elsewhere the most characteristic of these late bony changes. It is greatly thickened; its crest being no longer a mere ridge, but it has become a wide surface, swelling forward so that a side view gives a characteristic *sabre shape*.

27. In conclusion, it is a matter of great interest, that may well detain us for a minute to examine into the stigmata of a syphilis which was active in early childhood, but now is either quiescent or cured. The tibial and other bony changes just mentioned come under this heading ultimately.

Chronic fissures about the lips often exist in late cases, and these leave diagnostic linear cicatrices there. Small scars upon the skin or mucous membranes of children no longer in infancy deserve study. When of this nature they are apt to be in outline curvilinear or crescentic, in groups, and not rarely are symmetrical upon the two sides. They are especially diagnostic when found upon the upper part of the legs. Such signs imply that the child once had a rather severe type of the disease, though now, perhaps, cured.

It is my hope that among the gentlemen of wide experience present to-night there may be enough difference of opinion as to the value of some among all these twenty-seven signs to elicit an interesting criticism and discussion. Perhaps, too, they may suggest yet other stigmata deserving of mention, but overlooked in this paper. In both of these ways I shall hope to profit, and for all suggestions shall be grateful.

THE DIFFERENTIAL DIAGNOSIS OF SYPHILITIC ERUPTIONS AND SIGNS IN THE SKIN OF FORMER SYPHILIS.*

By GEORGE HENRY FOX, M. D.

It is a startling statement, but it is nevertheless a fact, that syphilis is the only disease which every practising physician is called upon to treat, whether he is located in the city or in the country. Whether his patients are rich or poor, of the highest social rank or from the lowest walks of life; whether his practice is limited exclusively to men, to women, or to children; whether he is the typical "family physician" or the specialist devoting his attention to the diseases of a single organ of the body; whether, in fact, he desires to treat syphilis or not, he can not, by any possibility, escape the necessity of now and then encountering this protean disease, and often in a most unexpected manner.

In the recognition of syphilis through its various

manifestations the student of cutaneous diseases possesses a notable advantage. While, in most cases of syphilis affecting the internal organs, the nature of the disease is more or less obscure and can only be elucidated after a careful study into the history of the patient, in nearly every case of cutaneous syphilis the diagnosis of the disease is written upon the skin. It is usually written, too, in characters so distinct and plain that "he who runs may read."

In syphilitic disease of the eye, the throat, the nervous system, and other organs, there is often a lack of any characteristic signs indicating the origin of the malady. The diagnosis is of necessity based upon the history of the case, and is often a probability rather than a certainty. In cutaneous syphilis, on the other hand, the lesions usually present such striking and pathognomonic features that the specific nature of the eruption is at once apparent to the eye of the observer. What Nature has written upon the skin is often perfectly plain to even those who have only learned their alphabet in the dermatological clinic. There can be no doubt as to the purport of Nature's handwriting. There is usually no necessity to inquire into the history of the case, except for the purpose of verifying the diagnosis.

The diagnosis of cutaneous syphilis rests upon the basis of clinical experience. We recognize an elm tree, an oak, or a maple, not because we have studied Gray's *Botany*, but because we have seen these trees from the days of childhood and have unconsciously noted their characteristics as manifested in leaf and branch. Those who are able to distinguish at a glance a chestnut from a hickory tree (and I presume some of us are not) have doubtless made a slight effort to acquire this knowledge; while those who are able to name the majority of indigenous trees have acquired their diagnostic skill only by tramping through forests with open and inquiring eyes. In like manner the physician who has the skill to instantly recognize syphilis whenever and wherever it may appear has gained this skill not in the library, but in the clinic. However valuable lectures, books, and plates may be, it remains a fact that only through the careful study of actual cases can one become expert in the recognition of syphilitic eruptions.

Among the chief characteristic features of the syphilitic eruptions may be mentioned color, absence of itching, and peculiarities of configuration. The color of a syphilitic eruption, though often typical, is rarely to be depended upon as a basis of diagnosis. The absence of itching which, as a rule, is common to syphilitic eruptions, has a few notable exceptions. In every pustular eruption where the lesions are numerous, and superficial crusts have formed, a moderate amount of pruritus is frequently present. The peculiar configuration of most of the syphilitic eruptions constitutes the most characteristic clinical feature and serves as the most reliable basis of diagnosis. In the early eruptions, those occurring during the first year of the disease and usually during

* Abstract of a paper read before the New York Academy of Medicine, March 2, 1899, in the discussion on syphilis.

the first three months, the lesions, whether few or numerous, are disseminated over the greater portion of the body and are perfectly symmetrical. In the case of certain relapsing eruptions a tendency to a corymbiform arrangement or grouping of the lesions is often noted, but still the eruption on one half of the body is usually duplicated upon the other half. In the later eruptions, those occurring after the first year, this symmetrical arrangement of the lesions is lost, and it may be laid down as a rule that the further removed the eruption is from the date of the initial lesions the greater is this tendency to become unsymmetrical and limited to a small portion of the body. The late lesions of syphilis are characterized by a tendency to grouping; to the arrangement of the lesions in a circle; to the peripheral or serpiginous extension of patches; and to gummatous ulceration.

The determination of the fact that a patient has, at some previous period, suffered from syphilis is often a matter of supreme importance. There are so many diseases in which syphilis may be justly regarded as a possible aetiological factor that the proper treatment of the case often hinges on the fact of antecedent infection. To determine this fact, the physician is usually forced to rely upon either the history given by the patient or upon demonstrable evidences of preexisting disease. The history elicited even from an intelligent patient is often negative, and is always an insecure basis of diagnosis. Many a man, in clinic or private practice, will present a tubercular, squamous, or ulcerating eruption which is unmistakably syphilitic in nature, and yet he may have no knowledge or recollection of any initial lesion or previous eruption. In the case of women it is even more difficult to get a definite history of syphilis, except in cases of repeated miscarriages, for the initial lesion often remains undiscovered by the physician shortly after the time of infection, and eruptions, sore throat, alopecia, and arthritic pains are not always due to specific disease. The oft-repeated statement that lying is a pathognomonic symptom of syphilis may be jocose, but in my experience it is seldom true.

The careful examination of a patient with a view to the determination of previous syphilitic infection is likewise often negative, for in very many cases the disease runs its course with, or even without, treatment and leaves no perceptible trace. But in many cases there are evidences of former disease, which can only be discovered by stripping the patient and making a most careful search from head to foot. In no case is a physician ever justified in arriving at a positive conclusion, and much less in certifying to the fact that a patient, whoever he or she may be, is free from syphilis. All that he can possibly know, all that he can state positively, is that at the time of examination the patient present no manifestations of either present or past disease. He may justly assume that there is no probability of syphilis in connection with the case, but never can he

assert of any patient, unless it be himself, that there is no possibility of syphilis in the case.

The cutaneous indications of previous syphilis, when no late eruption is present, may be either pigmentary or cicatricial. Discoloration of the skin, especially upon the lower extremities, may be left for months and even years after syphilitic lesions have passed away, but rarely are they of much service in determining the previous existence of syphilis. Cicatrices, on the other hand, often declare this fact and remain as a permanent record throughout the lifetime of the patient. There is nothing absolutely characteristic of a single scar left by a syphilitic lesion, but the number of the scars found upon the skin, their location, and their peculiar arrangement often proclaim their origin beyond all shadow of a doubt. A small, rounded, smooth, white, and depressed cicatrix is said to be characteristic of syphilis, but a red-hot iron might produce a scar of precisely similar appearance. When, however, a few such scars are arranged in a semicircle, or many of them are found together in a group, the question of former syphilis becomes simply a matter of justifiable inference. The location of cicatrices is often quite as characteristic of their syphilitic origin as their peculiar configuration. For instance, when a small, rounded scar is noted upon the lower portion of the leg, we know that the ulcer which produced it may have been either of traumatic, eczematous, or syphilitic origin; but when one or more such cicatrices are seen upon the upper third of the leg, and especially upon the inner aspect of the calf, we know that the probability of eczema or traumatism having caused them is so very slight that we recognize them at once as almost unmistakable evidences of former syphilis.

[Dr. Fox had a series of lantern-slide illustrations thrown upon the screen, and pointed out the clinical features of psoriasis, eczema, lupus, and epithelioma, comparing them with syphilitic eruptions of similar appearance. He also showed illustrations of variola, lichen planus, ringworm, alopecia, and other non-specific dermatoses which bear a resemblance to syphilis. He said that these illustrations would speak more eloquently and more instructively than anything that he might possibly say upon the subject.]

THE TREATMENT OF SECONDARY SYPHILIS.*

By R. W. TAYLOR, M. D.,
CLINICAL PROFESSOR OF VENEREAL DISEASES
AT THE COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY, N. Y.

THE task assigned to me by the president in this symposium on syphilis is to present a succinct and practical consideration of the treatment of this far-reaching

* Read before the New York Academy of Medicine, March 2, 1899.

protean infection, and I shall try to accomplish this end on broad grounds.

Before considering the subject of treatment proper, it is very important to call attention to certain vicious therapeutic methods which still prevail to a certain extent, but which I think are slowly passing into desuetude.

About twenty years ago a most unfortunate reaction took place in the method of treating syphilis. Prior to that time it may be confessed that the method of using mercury was in general rather too lavish in its doses, and that in some cases harm was done. But as I look back the conviction forces itself on my mind that the old-time Ricord plan of treatment (in vogue prior to 1870) in which an active mercurialization for six months, supplemented with three months' liberal dosage with the iodide of potassium, was, with all its drawbacks and imperfections (chiefly salivation and intestinal derangement), far more beneficial than the attenuated, emaculated, narrow-gauge, stencil-plate methods of treating syphilis which then were adopted in France, England, and America. The reaction from the vigorous use of mercury was too radical, and I am sorry to say that we complacently accepted a method of treatment built up on theories and fantastic reasoning, which, in my judgment, has proved to be one of the most calamitous events in medical history. We hear little to-day in America of the ingenious and sophistical reasoning of the accomplished author of the interrupted treatment of syphilis, and there are few who wrestle with the labyrinthine problems of dose arithmetic, with its "full dose," "tonic dose," and "reserve dose," in administering mercury according to the tenets of the preposterous tonic treatment. But, although these ingenious theories are either entirely forgotten, or unknown to the present generation, the trail of the serpent is still visible in the routine methods followed by many in blindly relying upon the stomach ingestion of insoluble preparations of mercury in small doses. Happily for the human race, this slipshod, happy-go-lucky method of treatment is less and less followed every year.

In order that syphilis may be cured, it is necessary to introduce into the system a sufficient amount of mercury to act upon its poisonous products. Now, to take mercury into the stomach is not of necessity to introduce it into the system. Whatever mercurial agent is swallowed, be it the protoiodide of mercury, mercury and chalk, blue mass, the tannate, salicylate, or the dimethoacetate, all of these insoluble preparations must be acted upon in the intestinal canal and converted, in whole or in part, into peptonates or albuminates. In these forms they are taken up by the blood vessels and lymphatics, and by them distributed throughout the system. When the conversion of the ingested mercurial is perfect and in full quantity benefit occurs, and the syphilitic cells and toxins are favorably acted upon, and the auspicious condition prevails so long as the mercury

assimilation is perfect and its systemic distribution is thorough.

A consideration of these facts shows us what a great additional strain or burden is placed upon the intestinal functions, which not only have to assimilate for the support of the system the nutritive properties of the food ingested, but, in addition, two or three times each day to convert an indigestible and foreign drug into an assimilable chemical preparation.

Time will not permit me to go into all of the considerations involved in these minute processes, and I shall have to content myself by a succinct statement of what chemistry and clinical observation have shown to occur to syphilitic patients who for long periods have been submitted to mercurial treatment by the mouth. Chemical examinations have shown (and any one can ascertain the facts for himself) that when mercury does not produce gastro-intestinal derangement, a goodly amount of the drug is absorbed, as shown by its excretion in the urine and feces. When matters thus progress favorably the effect upon the syphilitic condition is beneficial, but as time goes on chemical examinations show that the quantity of mercury assimilated grows less and less, and that, though taken by the mouth, it is not absorbed, and that its therapeutic effect is then lost.

Now, clinical observation has clearly shown that for a time, in the early weeks of syphilis, a decidedly beneficial effect is produced upon the disease by mercury given by the stomach, but that in a few weeks the therapeutic action begins to wane and soon the remedy becomes inert. It is this temporary action of mercury given by the stomach, in long-continued and interrupted courses, which has brought to thousands of patients great trouble and suffering, misery, disaster, and death. They took the remedy long after it ceased to have any therapeutic effect, and the unextinguished infection kept right on its course of invasion and destruction. I scarcely know of a more difficult task than that of curing an old syphilitic who presents more or less distressing or dangerous lesions, for which he has long undergone an attenuated and prolonged mercurial stomach medication which kept him on the ragged edge and failed to dislodge his enemy.

I think I need add no more to this particular subject than to give the more recent utterances of the learned originator of the interrupted method of treatment of syphilis by small doses of the protoiodide of mercury. In 1870, he contented himself with the statement that two years and a half of this treatment were sufficient for the cure of syphilis. In 1889, he says that syphilis is an infectious, chronic, constitutional disease, diathetic, like gonorrhea and scrofula, and should have a lifelong treatment. Another author, of the same system of therapeutics, advocates a life-long cure, while still another eminent man of the same treatment should be indefinite. For my own part, I am convinced toward the close of the seventy-decennary of the century

that these treatments just considered were dire failures, and that they might, without exaggeration of speech, be termed curses of humanity. It is considerations like the foregoing which prompted me to use insoluble mercurial preparations only in the first few weeks of the secondary period, and then to use such efficient methods as would introduce into the system a sufficient quantity of mercury to act upon the syphilitic diathesis and not produce any depressing effect upon the general economy.

I will now succinctly describe what I consider an efficient and trustworthy method of treating and curing this chronic infective process.

In order to understand how to treat syphilis successfully, it is very necessary to have a clear idea as to its nature. Clinical observation and the analogical evidence presented by many infectious processes quite clearly indicate that syphilis is essentially due to a micro-organism, though such has not yet been demonstrated.

The poison of syphilis having been implanted upon the tissues of the infected person at once strikes for the vessels, and as a result there is marked distention of the perivascular spaces with small round cells, which produce a coat-sleevelike sheath around these tubes. The infective process thus beginning as a periphlebitis and periarteritis runs rapidly down the vessels, and within a few days the tissues far away from the chancre are honey-combed by these infected blood channels.

The process of syphilitic infection, therefore, is one of constant growth and diffusion from the beginning. In the very first days of the existence of the chancre the poison is deeply rooted in the subcutaneous tissue. It is in a most active state, and progresses along the course of the vessels until it reaches the body, and then infects the whole economy. In consequence, it is very certain that excision of the chancre will not cause the abortion of the disease. Reasoning by analogy, we are warranted in assuming that this new, highly infectious, and rapidly growing tissue gives off, probably by means of its microbes, a poison which diffuses itself through the system. We have, then, in syphilitic infection two orders of morbid changes: (1) The heterologous new cells; (2) the diffusible poison.

This, then, is the condition we have to treat, and the question arises, When shall active medication begin? My experience has taught me that the best results are always attained when treatment is commenced just as soon as the secondary manifestations show themselves. I am not a believer in the early mercurialization of syphilitic patients, for the following reasons:

1. My experience (and I am in accord with most advanced siphilographers) has taught me that when the morbid processes have so far advanced that a generalization of their products has occurred, syphilis may be said to be ripe, and then, and not till then, have we anything really tangible to treat. Mercury given before this critical cell distribution has very little to work

upon, and therefore is productive of a very limited amount of good. Indeed, to my mind, when given thus early, while it may have some influence upon local processes—on parts that are the seat of the chancre and the adjoining territory—it is productive of harm by influencing the tissues too early, which influence does not give them an immunity to the subsequent syphilitic process of invasion. In other words, mercury given before the generalization of syphilitic products does not favorably influence the resistance of the tissues to the impending invasion, and certainly does not render them immune to it. On the contrary, the early exhibition of mercury induces a condition of tolerance in the tissues which renders its action less powerful and effective at a later date when they are infiltrated with syphilitic products. In short, we remove the cutting edge of our most potent remedy by administering it to a system not as yet thoroughly charged with the virus which it is our hope to destroy. We are really treating before we have anything to treat.

2. Early treatment does not suppress or annihilate the disease, but simply retards the evolution of the secondary manifestations, and induces a subsequent disorderly course. On the other hand, by waiting until the disease is ripe and then beginning a vigorous course of treatment, it may be entirely cured, and no further manifestations may be seen or felt.

3. In most cases it is of great importance that the patient shall see for himself that he has syphilis, and when following the chancre he feels the enlargement of the neighboring ganglia and sees an unmistakable generalized eruption, he becomes thoroughly convinced that he is really syphilitic, and will then follow treatment in a systematic manner. On the other hand, if the patient only sees the chancre, and if the evolution of the secondary period is postponed by early mercurialization, he is very apt to think that he has escaped the infection, and will not follow treatment.

4. Errors in diagnosing genital lesions are so commonly made by the profession, owing to the fact that so many simple affections resemble the syphilitic chancre, that it is, as a rule, well to wait until the specific nature of the sore is confirmed by evidences of generalized systemic infection.

In this connection it is well to emphasize the fact that many men have been rendered unhappy for the balance of their lives in consequence of a false diagnosis of syphilis having been made upon some benign genital lesion.

5. No advantage or possible benefit to the patient is lost by withholding mercury until the onset of the second stage; nor is the patient thereby put in any jeopardy, present or future; nor are his chances for ultimate permanent cure in any way impaired, modified, or crippled. On the other hand, his syphilis will be more orderly and conspicuously more amenable to treatment; his physician will not grope in the dark, and will, if

he promptly attacks the disease in the conservative but vigorous manner soon to be detailed, be spared the hesitancy, doubt, and uncertainty of mind which are the inevitable lot of those who attack the disease prematurely.

The date, therefore (as a general rule), at which the treatment of syphilis should begin is that at which the disease culminates in the general infection of the economy—namely, just as soon as the general rash appears, together with the other manifold symptoms of the secondary period.

Too much stress certainly can not be laid upon the fact that in the early secondary stage there are certain conditions favorable to an active treatment—namely, a system virgin to mercurials and a greater susceptibility of the lesions to the action of mercury. This, then, is the most favorable time for efficient treatment, and it is the most critical one in the life of the syphilitic, for if the disease is attacked then its backbone may be broken. It is very probable that much of the late rebelliousness and malignancy of syphilis is due to the fact that the newly formed infecting granulation cells and the concomitant subacute inflammation, together with the diffusible toxins, induce in organs and tissues, particularly delicate ones, such as those of the nervous system, structural and nutritive changes which predispose them to subsequent low grades of inflammation and cell increase, besides, to a repetition of the essential syphilitic process. Therefore every effort should be made to destroy these young infectious cells and to remove them as quickly as possible from the parenchyma of organs and tissues before they shall have had time to induce these subtle and dangerous structural changes. In proportion as a systematic and vigorous mercurial course is entered upon late, so it is more and more heavily weighted in its action. There is no doubt whatever in my mind that a mercurial treatment covering the first six months of the disease is far more salutary and effective than a course extending over a year and more instituted later on.

It is important in the treatment of syphilis that the physician should have a good general idea as to the constitution of his patient. In a general way, it may be stated that the larger number of persons who contract syphilis are those who are young and in average good health. In a smaller number the standard of health is less high, and in some patients certain morbid conditions exist which are due either to disease or bad habits, and which lower their power of resistance.

There are many persons who, though not absolutely sick, are not really well. In this category are included cases of anæmia; flabby, and poorly nourished individuals; blonds with light reddish hair; persons suffering with malnutrition, and even those who are mildly neurasthenic. Then, again, we observe cases in which the health is impaired by worry and grief, by business cares, doubts, dreads, and excitements, also by insomnia. All such may be said to suffer from lowered vitality, and in

them syphilis is apt to run a more or less severe course. In the treatment of these cases we may not experience the quick response to the administration of mercurials; the manifestations may be rather slow in disappearing, and others may show a tendency to reappear. The cure, therefore, is not produced quite as quickly as in the benign cases, but, although the case may hitch and halt, neither physician nor patient should falter. In America syphilis in women runs about the same course that it does in men, but the female sex is much less frequently attacked by cerebral and cerebro-spinal affections than are men. Women, as a rule, are less addicted to alcoholics than males, and they are not called upon to overtax the brain as many men are, consequently they present rather infrequently evidences of specific nervous affections.

Syphilis in healthy persons, male and female, as a rule, runs a mild course, and its poison is eliminated from the system if active treatment is instituted at the proper time. Much depends upon the intelligence and docility of the patient, who, if he enjoys ordinary good health and will follow up energetic but very carefully directed treatment, may, I am confident, be cured. This comforting assurance may be given to the majority of patients seen in private practice, who, in general, are intelligent, realize the gravity of their condition, and resolve to so conduct themselves and regulate their habits that their vital processes can resist the depressing influence of the syphilitic poison and be able to undergo the strain put upon them by long-continued medication.

When we come to carefully study the treatment of syphilis proper, it is apparent that it is far from being a matter of routine or a mere problem of dose arithmetic. To be thorough and successful it must be based on broad principles, upon an accurate and full knowledge of the disease, and upon frequent and thorough study and observation of the patient. In the course of syphilis many conditions, exigencies, and complications are apt to arise, and the physician, to be successful in its cure, must be ready with all known modifications and expedients of treatment.

Assuming, now, that the patient has just presented evidences of the generalized manifestations of syphilis, the treatment is at once commenced. It is always well to begin medication in a manner that will not annoy, disgust, or discourage the patient, who is usually in a rather unhappy frame of mind at the thought that he is syphilitic and that he has quite a long period of treatment before him. Therefore, it is not well to be precipitate in the institution of an immunization treatment. Since in these early days mercury by the mouth is generally well borne, is effective in result, and is not distasteful to the patient, he may at once be put upon pills of the protoiodide of mercury, or of iodate of mercury, or of the thymoliodate of the same. In general, half-grain doses of these drugs may be given three times a day, and it will be rarely necessary to increase the daily

amount taken beyond two or three grains of any of them.

It is important that this initial course should be active and rather prolonged, and in attaining this end the case must be carefully handled and watched. As a rule, the physician can form a correct estimate as to the probable effect of mercury upon his patient within a week or ten days. Having put the stomach and intestinal canal in normal condition, and the mouth and throat having received proper attention, the dose of the mercurial may be increased within a few days to the quantity which acts vigorously on the lesions and does not disturb the well-being of the patient.

We must at this time assure ourselves that the indurated nodule has wholly disappeared; that the lymphatic engorgement shows evident signs of involution, and that the rash has faded or is fading. The throat and mouth must be inspected very often, and any red patches or ulcerative lesions must be actively treated. It is always a good rule as the rash is declining to discontinue the pills and to give the patient one or two courses of mercurial inunctions, by which the whole surface of the body will be acted upon by mercury. In this way any infectious cells which may be left over from a local or general rash may be acted upon and destroyed. Even while the patient is taking pills mercurial ointment may be used locally upon the lymphatic ganglia, due care being taken that an overdose is not given. In like manner papular and pustular lesions in hairy parts should be treated locally. The physician should always remember that all syphilitic lesions, even the most minute, are to be feared as possible sources of continuous or intermittent reinfection of the system. The morbid cells contained in these lesions are capable of great, even infinite, multiplication, and it can not be too clearly borne in mind that the so-called syphilitic relapses are due to the recurrence of these cell proliferations which develop from morbid foci left over at an earlier date.

By thus at an early date inducing the patient to use inunctions of mercurial ointment as an adjuvant treatment, it is seldom difficult, particularly with intelligent persons, to gain their consent to follow a full inunction treatment, and then the use of the pills may be discontinued. In proportion as the case progresses well the fear of the disease by the patient is dissipated and his morale improves. At this time the assurance on the part of the physician that the patient will be very much more benefited by systematic inunction treatment generally results in the patient's consent.

To be effective, the mercurial inunctions should be thoroughly administered over the whole body in regional parts, using about sixty grains of mercurial ointment. In some cases the inunctions may be administered on consecutive days; in others there may be intervals of one or two days between each. Usually after fifteen or twenty inunctions a period of repose may be allowed for

a week or two, since after such a course fully three or four weeks elapse before mercury ceases to be eliminated in the urine and feces.

During this initial active and energetic course we must take especial care of the patient's nutrition and be watchful of his well-being. If possible, change of air and scene at the seaside or the mountains should be enjoyed, and as much recreation indulged in as possible. The lighter the patient's cares and the less burdensome his condition of life the more auspicious will his progress toward cure be.

While a patient is undergoing this mercurial course he should have one or two warm baths each week on going to bed, in order to produce diaphoresis. When practicable, he should take Turkish baths, without the plunge, and after them should be made to sweat freely. At the seaside cold salt-water baths are very beneficial, and an occasional hot sea-water bath, followed by packing and a sweat, is a valuable adjuvant to mercurial treatment.

Since we know to-day that the cell proliferation of syphilis develops a diffusible poison which gives rise to various phenomena—fever, debility, emaciation, headaches, neuralgias, arthralgias, periosteal pains, splenic engorgement, and pleuritis—it has occurred to me that, besides the use of mercury, we should use at times, in combination, the remedy which seems a specific for these disorders—namely, iodide of potassium. Study and experience have taught me that we should not too long defer the administration of this valuable drug. Therefore, either synchronously or in the intervals of disuse of the mercurial frictions, we should give the iodide in goodly doses—ten, twenty, or thirty grains three times a day, or even in larger doses.

Then, again, it may be necessary, for various reasons, to suspend the inunction treatment for a long or short time, and in this event I do not go back to the pills, but use a strong mixed treatment, as follows:

R: Hyd. binod.	gr. ij to iv;
Potass. iodid.	ʒss. to ʒj;
Tinct. cinch. co.	ʒijj;
Aque	ʒj.
M. ʒj ter in die ex aqua ʒj.	

In this way we can push along until six months have elapsed from the date of the onset of the secondary period of syphilis, during which time the patient has taken medicine more than five months. In most cases, if this carefully regulated and most effective treatment has been followed, an examination of the patient will show that he presents no evidence of the disease, and that his condition is most satisfactory. As I have said before, it is evident that the backbone of the disease has been broken. Then the patient may have a respite from medicine for two or three weeks. At the expiration of this time the treatment must be kept up for three months longer, and it must consist of alternations of the inunction treatment and the dosage with a mild or

strong mixed treatment. As a cure progresses the intervals between inunctions may be longer and the mixed-treatment dosage may be less strong.

After the lapse of a year, in many cases, the necessity for treatment may not be apparent, and most of these patients say that they think they are perfectly well. It is better, however, not to take any chances, and during the second year, and perhaps a little longer, a few courses of inunctions and of the mixed treatment may be taken.

In the carrying out of this methodical general treatment of syphilis in the second year of the disease, the periods of dosage may on an average be stated at two to three months, with intervals of a rest of a month or six weeks. In this way about eight months are occupied by actual medication. In most cases at the end of the second year of thorough treatment patients may be pronounced cured, provided they have not for many months shown evidence of the disease, that their lymphatic system appears healthy, and their general health and nutrition are good.

With the foregoing considerations in mind, I see no reason whatever for altering the opinion that I have many times stated, that if an energetic and thorough treatment, such as I have sketched, be followed for two years or two years and a half, the patient will be cured, as shown by freedom from all syphilitic manifestations, by his or her ability to procreate healthy children, and by the enjoyment of permanent good health.

In addition to the foregoing methods of treating secondary syphilis, the physician should always be familiar with the technic of hypodermic injections of bichloride of mercury, and should use them as a reserve and expediency treatment. He should also bear in mind the fact that mercurial vapor baths have a limited but important sphere in the treatment of secondary syphilis.

THE TREATMENT OF SYPHILIS.*

By L. BOLTON BANGS, M.D.

THE disease called syphilis is still of untold interest. Its peculiar lesions, its liability to crop out after periods of quiescence, its non-limitation to any organ or tissue, but its capability of attacking all organs and tissues, and the mysterious appearance of its effects (so-called "sequela") many years after its acute stage has been forgotten bring it within the observation of all physicians. The specialist may, and probably does, see it mostly in its early and external manifestations; but when it assaults the internal organs, when symptoms are vague and obscure, and a careful and discriminating diagnosis is to be made, to whom then does it become an object of special study and interest but to the general practitioner?

There is also an attractiveness in its study because of our ignorance (or, rather, lack of positive knowledge) of its essential causative factor. Analogy and clinical study lead us to the conclusion that it is of microbic origin. To quote from White and Martin: "A number of bacteriologists have announced the discovery of this microbe, but convincing proof of the direct relation between the micro-organisms described and the specific lesions with which they have been found associated is still wanting." Without doubt further observation will provide us with this convincing proof. For the present we are able to maintain that after its introduction into the body this micro-organism or germ proliferates, sometimes enormously, but not *indefinitely*, for there is an apparent self-limitation to this as manifested by the cessation of symptoms and of contagiousness independently of any treatment. The multiplication of this germ produces such a reaction on the part of the tissues that not only is there elaborated a product which may be regarded as a protecting principle (*i. e.*, an "antitoxine"), but which also induces localized cellular inflammation exudates, with, in some cases, subsequent development of connective-tissue deposits. These localized cell accumulations interfere with the physiological function of the parts wherever situated, and, producing the various lesions of the disease, evidently contain the active principle or virus, for they and their discharges are contagious—certainly for two or three years.

Histological investigation of these products of syphilis shows them to consist essentially of immature cells in the walls of the lymph channels, in the parenchyma of the glands, and in and about the walls of the blood-vessels. These phenomena may be, and probably are, in response to the efforts of Nature to prevent and to repair damage to the tissues; but, as in many other of Nature's efforts when unaided by art, the results may be disastrous to the individual who is the subject of them. The object of treatment, as I understand it, is to prevent these cell accumulations if possible; to modify them and to hasten their involution or absorption, without injuring or weakening the healthy or fixed structures. Although syphilis manifests itself in many varying forms, from the mildest to the most severe or so-called "malignant" form, the fact that many individuals have passed through the acute stages of the disease without any treatment whatever, and have never afterward had any syphilitic evidences, warrants the belief that there is some quality in the (blood and) tissues which destroys the elements of infection and removes their pathological products. But, whether or not we can rely upon this quality to combat the infection and eliminate its toxins, experience has taught us that art *can* aid in the removal of their pathogenic results. From time immemorial almost, one drug has been the potent agent employed against syphilis—namely, mercury—and although, in my opinion, not an antidote, it

* Read before the New York Academy of Medicine, March 2, 1899, in the discussion on syphilis.

certainly does have the most efficient action upon the symptoms of the disease. So far as my knowledge goes, nothing has been presented in later times to disprove the statements of Headland in regard to the action of mercury, and upon these may be based a scientific reason for the use of the remedy. Headland long ago showed that mercury, when properly administered, produced a fatty degeneration of tissue, especially of the unstable or plastic effusions which took place in various diseases, and that the results of this fatty metamorphosis, being taken up by the lymphatics, was passed out of the body through the various excretory organs.

But it is not enough to say that a man has syphilis, and therefore he must take mercury. If we are to obtain the aid of the antidotal quality of the blood and of his tissues in general, he must be maintained at the highest possible level of health; he must not indulge in any of the things which are known to cause degeneration of tissue; in other words, his life must be a hygienic one through the whole course of his treatment. Although such a statement is in accord with experience, it is a general one, and may be modified according to the individual, for all physicians have met with patients—to be sure, robust, healthy, vigorous ones—who obstinately refused to follow the instructions of their medical advisers, and yet were apparently able to resist the progress of so infectious a disease as syphilis. It is these individuals who illustrate the self-limitation of syphilis above alluded to. Generally speaking, however, a hygienic mode of life is essential as the first step in treatment.

If, on account of some idiosyncrasy of the patient, mercury can not be given, other remedies which have a similar physiological action may be used; but mercury is the best and most potent, and indeed may be said to be the specific remedy for this disease. At one time potassium iodide was considered equally valuable, but clinical observation and scientific research go to show that while mercury admittedly produces this fatty metamorphosis to which reference has been made, iodine and its compounds merely stimulate the absorbents and hasten the elimination of the products obtained by the action of mercury. Even in the later stages of syphilis, the so-called tertiary period, and even when we have reason to suppose that the earlier granulomata have been followed by connective-tissue changes, mercury should be administered, but in combination with increasing doses of potassium iodide. The latter is, in my opinion, rarely indicated during the early stages of syphilis unless central or nerve lesions have occurred, or where a rapid elimination of the products of metabolism induced by the use of mercury is indicated. Then it should be administered only as an adjunct to the principal remedy.

In some individuals, besides mercury, it may be necessary to use other measures which produce tissue metamorphosis—such as hot baths, douches, massage,

ing, special exercises, and periodical changes of climate. To the latter, aided by hot baths, etc., I am inclined to attribute much of the rapid improvement which is obtained by patients who visit the various springs and other hydropathic resorts.

As to the best *method* of treating syphilis, I am free to say that the method must depend upon the nature of each individual case, remembering always that the patient is to be treated and not merely the disease. Although the foundation of the cure may be said to rest upon the fact that the patient is able to take mercury, whether by the mouth or by inunction, by vaporization or hypodermically, much will depend upon the idiosyncrasy of the individual and the skill and experience of the practitioner.

When and how shall we begin treatment? What shall be done for the initial lesion, and shall we at once begin constitutional (so called) treatment?

Notwithstanding all that has been said and written against excision of the initial lesion, I am inclined to practise the latter whenever the lesion is so situated as to make it feasible. Admitting that the disease is already constitutional when the initial lesion is first observed, experience warrants me in the statement that an infecting mass may be disposed of and the subsequent events of the disease may possibly be modified by early excision of the initial lesion. Whether we regard the primary adenopathy and the first macule of syphilis as the result of toxines produced by tissue reaction or not, I think we may fairly and reasonably look upon the initial lesion as a depot or reservoir from which the infectious elements were and yet may be started in their process of multiplication; therefore it ought to be removed. In some individuals the initial lesion is so situated that it can not be excised without a degree of mutilation which is unwarranted. On the other hand, domestic or social reasons may demand a speedy removal of the local lesion, which may be secured by excision and by securing primary union of the little wound.

Whether excision is practised or not, it is generally admitted, I believe, that the involution process of the initial lesion may be hastened by local applications to it of mercurial preparations, and by the *internal administration of the same remedy*. This leads me to the question, which has been discussed with more or less earnestness for some years—namely, whether we shall wait until the end of the second incubation period before beginning constitutional treatment, or whether we shall commence at once—i. e., as soon as the diagnosis of primary syphilis is determined. In my opinion, it is best to begin at once. Our objects, as stated in the earlier part of this paper, are, if possible, to prevent the disease from becoming severe; to interfere with the multiplication of the microbe bodies upon which it depends; to relieve the tissues of their cell accumulations, and to maintain the organism in as healthy and resisting a condition as we can. Our object is not to make a diag-

nosis and then wait for confirmatory proof, but to heal the individual who is diseased, who is infectious, and in whose body circulates a material which feeds and multiplies upon the tissues of that body. Why wait, if we have a means—call it what you please—an “antidote,” or a “germicide,” or an “alterative,” or what not; but if it is a means which has undoubted and admitted power, why not employ it at once from the very moment that we are certain that the individual has a disease it is our duty to combat?

If it is admitted, as it seems to be by the majority of syphilographers, that histologically all of the secondary manifestations of syphilis are found to be composed of the same cell accumulation, with perhaps the development of a few connective-tissue fibres, as compose the initial lesion itself, why should it be argued that there is “nothing to treat until generalization has manifested itself”? Again, if specific treatment of the initial lesion be warranted in particular cases, why is it not warranted—and indeed required—in all cases?

If, then, an initial lesion is present, and if specific treatment is good for it, why not begin at once the administration of that remedy which we know hastens the involution of those manifestations which belong to the so-called generalized or secondary stage? In my opinion, the effects of syphilis are due not only to the mechanical interference with the function of the part or parts where these exudates take place, but also to a systemic poisoning due to the elaboration and circulation of a toxine or ptomaine produced by the microbe body itself. If the vital forces of the individual are maintained at what might be termed a par of health, and all his functions kept at the highest point of activity, his economy is better able to take care of the toxines, while by the judicious administration of mercury his body is enabled to dispose of the granulomata or cell accumulations in their varying grades of intensity. This implies constant watchfulness, the exercise of careful, discriminating judgment, and, in some cases, ingenuity, on the part of the doctor, and on the part of the patient of obedience, confidence, and patience.

We know that the intensity of the disease depends not only upon the activity of the virus but largely upon the vulnerability of the individual himself, and we also know that by the too vigorous administration of mercury the healthy tissues of that individual are rendered less resistant to the inroads of syphilis. Thus may be substituted or added the toxic effects of the drug to the toxic effects of the disease, which, if left to itself, will in many cases, at least, pursue a certain chronological order, and, so to speak, finally wear itself out. Hence the object in view is to administer this potent remedy only for the purpose of assisting the economy to counteract the effects of the infectious principle and the toxines which it generates.

As to methods of administration: if the remedy is well borne when taken by the mouth, this is the prefer-

able mode. Only so much should be administered daily as can be digested easily and freely without interfering with stomach and intestinal digestion, but up to the point of the drug's physiological action. In the majority of cases an habituation to the remedy ensues, and therefore I am accustomed to make intermissions in the treatment from time to time; always, however, maintaining the hygienic and dietetic *status quo* of the person. It should be observed that many persons do not bear the internal administration of mercury up to the point that may be necessary to act vigorously upon their lesions. In such cases the method of inunction should be resorted to at once. This is less depressing than the vaporization method, is not at all painful, and in spite of the staining of the skin is less disagreeable than the hypodermic method, and is often brilliant in its results.

It is my custom during the course of the treatment of syphilis to intermit the internal administration of the drug, even if it is well borne by the stomach, and substitute inunctions, always keeping in view the general principles upon which the drug is administered.

In certain malignant forms, where the tissues of the individual seem to be rapidly breaking down as a result of the disease, hypodermic injections of the bichloride may be given with very prompt effect. They should be repeated with care, bearing in mind the fact that death has ensued from this method of using the drug. With ordinary precautions, however, and choosing the buttocks for the site of the injections, there is, in my opinion, but little danger.

Even in cases of malignant syphilis the effect of the injections should be watched very closely, and every possible accessory measure taken to increase the general well-being of the patient.

One of the most important guides to indicate the period during which treatment should be carried on is the condition of the glands throughout the body, particularly the epitrochlear and those which are not usually found enlarged in the more common dyscrasias. So long as these glands remain enlarged, it is one indication at least that treatment should not be discontinued. Enlargement of the glands alone is not positive evidence of syphilis, but if the practitioner has followed his patient from the onset of the disease, and has appreciated that these enlargements have grown smaller or disappeared entirely under treatment, it is confirmatory evidence that they are syphilitic in their nature. If the individual gives a suspicious history and has glandular enlargements, it is well to give him the benefit of the doubt and administer mercury; but, at the end of three months, say, if no material change has taken place in the size of the glands, it may be reasonably concluded that connective tissue changes have occurred in them to such a degree that they are now permanently enlarged.

The duration of the treatment, irrespective of the state of the glandular system, will depend somewhat upon the individual and the continued activity of his

disease. But experience teaches that long-continued and gentle treatment for *at least* three years (some authorities say five, and one has lately urged seven) affords the patient protection from the effects of the disease later in life.

A FURTHER REPORT ON THE USE OF "ANTIPHTHISIC SERUM, T. R." (FISCH), IN TUBERCULOSIS.

By A. MANSFIELD HOLMES, A. M., M. D.,
DENVER, COL.

(Concluded from page 445.)

SUMMARY OF CASES.

Class I.

Case.	Duration of treatment.	Since close of treatment.	Results.	Resident of Colorado.
1	3 months.	9 months.	Cured. No relapse.	3 years.
2	3 months.	10 months.	Cured. No relapse.	19 years.
3	1 month.	14 months.	Greatly improved.	6 months.
4*	2 months.	9 months.	Renewed treatment. Improving.	2 years.
5	2 months.	10 months.	Cured. No relapse.	4 months.
6	3 months.	11 months.	Good. No relapse.	6 months.
7	1 month.	10 months.	Good. No relapse.	3 months.
8†	3½ months.	6 months.	Cured. No relapse.	1½ months.
9	1 month.	13 months.	Improved. No relapse.	(?)
10	2 months.	Treatment continued.	Improving.	11 years.
11	4 months.	Good. Improved.	6 months.
12‡	2 months.	Treatment continued.	Improving.	6 years.

Class II.

1‡	8 months.	5 months.	Cured. No relapse.	1 day.
2‡	2 months.	13 months.	Cured. No relapse.	2 months.
3	4 months.	8 months.	Improved. No relapse.	1 month.
4	2 months.	11 months.	Improved. No relapse.	3 years.
5	2½ months.	2 months.	Distinct improvement.	2 months.
6	5 months.	Continued.	Improving.	2½ years.
7	3 months.	Continued.	Improving.	3 months.

Class III.

1	8 months.	6 months.	Cured. No relapse.	2 years.
2	8 months.	7 months.	Improved. No relapse.	4 years.
3	2½ months.	Continued.	Improving.	6 months.
4	6 months.	Continued.	Marked improvement.	1 day.

Class IV.

1	2 months.	5½ months.	Became worse. Final results unknown.	2 months.
2	2 months.	1 month.	Died.	1 month.
3	1 month.	1 year.	Became worse. Final results unknown.	3 months.
4	1 month.	Died.	3½ years.
5	3 months.	8 months.	Improved. No relapse.	6 months.
6	2 months.	8 months.	Improved slightly.	8 months.
7	5 months.	1½ month.	Improved slightly. No relapse.	3 months.
8	5 months.	6 months.	Improved. Relapsed and rapidly failed.	2½ years.

* Relapsed at end of nine months.

† Reacted to "O. T." test before beginning serum.

‡ Tuberculin test at close of treatment. No reaction.

The ultimate summary is as follows:

CLASS I.—Twelve cases; ten patients discharged; nine have remained well to date, and one case relapsed at end of nine months; renewed treatment and patient is rapidly improving. Two patients not yet discharged, but are improving.

CLASS II.—Seven cases; five patients discharged; two cured and three greatly improved. Two continue the treatment and are improving.

CLASS III.—Four cases; two patients discharged; one cured and one greatly improved. Two patients continue the treatment and are improving.

CLASS IV.—Eight cases; two deaths; two patients became worse under the treatment, were discharged, and returned to their homes—results unknown. Three improved and have had no relapse. One improved and relapsed.

A study of the foregoing case has given me a broader conception of serum therapy in tuberculosis, and in conclusion I wish briefly to note a few of the points which have appealed to me with greatest force. I wish it understood, however, that I do not profess to be dogmatic in my deductions. My cases I report simply to bring them to the notice of other observers, with the hope that we may be of mutual help in our efforts to understand the nature of tuberculosis and antitoxine therapy.

In a study of tuberculosis we should always keep in mind these factors: (a) The degree of impaired resisting power of the patient; (b) the degree of virulence of the infecting germs; and (c) the relation which these two factors bear to each other.

(a) It is an undisputed fact that certain species of animals possess little or no susceptibility to tubercle bacilli, while others are susceptible to a high degree. These differences demand an explanation.

Recent investigations in this direction have led us to believe that *predisposition* on the one hand and *immunity* on the other are conditions of the organism resulting from a poverty or abundance of certain specific antitoxines, and, furthermore, these antitoxines are supposed to have their source in the leucocytes and tissue cells of the organism under consideration.

After a prolonged study of cells in tuberculous blood it is with no hesitancy that I repeat the statement which I have formerly made, that the physiological chemistry and the morphology of such cells reveal certain deviations from normal characteristics. These changes I have interpreted as signifying an impoverished state of the cells, and, as a natural accompaniment, an impaired functional activity of such cells. Therefore, if we accept as a fact the hypothesis that cells are antitoxine producers, it follows that if they are poorly nourished and overworked this function, with others, must suffer. Hence, we can understand why the tuberculous patient is not able to produce a sufficient antitoxine supply.

I, therefore, accept as fundamental principles that tuberculous persons are deficient in tuberculous antitoxines. Furthermore, that this deficiency in antitoxines results from a diminished antitoxine generating power of the leucocytes and tissue cells of the patient. Hence, it would seem that if the patient is reinforced by the daily administration of antitoxines prepared by an animal possessing a higher degree of immunization, the overworked leucocytes and tissue cells of the patient

will be relieved from excessive labor and will have an opportunity to recuperate. With needed rest, recuperation follows. Cell functions are strengthened, and hence the unaffected tissues are better able to protect themselves against a further invasion of the bacilli.

A successful therapy must aim first toward preventing a further extension of the disease. This of necessity must come by increasing the resisting power of the tissues not yet affected. If the administration of antitoxines has the effect of reinforcing the unaffected parts of the body and protecting them against a further extension of the infection, our first object in therapy is accomplished. Our next duty is to inquire into the lesions already existing, and especially as to the destiny of the germs in these lesions.

From the nature of the conditions there are four possible destinies for the germs: (a) They may make their escape through the blood or lymph channels to other parts of the body and establish new foci of infection. (b) They may succumb to phagocytes while attempting to establish new foci. (c) They may become encysted and remain in a latent state within the body. (d) Or they may make their escape from the body in the sputum or other excreta.

One of the preconceived ideas which has been extensively held concerning the use of serum in tuberculosis is the one bearing upon the time required to bring about results. So far as I have been able to learn, we have expected results too soon. Perhaps the most valuable point which I have learned from these observations is the fallacy of rapid cures from serum therapy in tuberculosis.

I have found it one of the most difficult things to bring about a complete disappearance of bacilli in well-established cases. My experience has convinced me, however, that actual cures in such cases can be effected even when bacilli are abundant, but a much longer time is necessary to accomplish these results than is generally supposed. I deem it important, therefore, to devote a portion of this report to the discussion on this point.

In order to obtain a correct understanding of the effect produced by serum in tuberculosis, it is first essential to form a correct conception of the nature of the pathological condition with which we have to deal. It is frequently the case that we centre our thoughts upon one part of a subject, while others, equally as important, are overlooked. In the study of serum therapy in tuberculosis I believe the error has been made of devoting our attention too exclusively to the nature of the toxins and antitoxines, while the nature of the disease—the pathology of the tubercle—has been to a great degree overlooked.

Tubercles are neoplasms. They are not only delicate of blood vessels, but they force their way into its anastomoses and tend to occlude the vessels already existing near them. Hence, they tend to shut off their own

blood supply and nutrition. These conditions are primarily the cause of the disintegration which necessarily follows. Furthermore, the conditions which shut off the blood supply to the tubercle also shut off the antitoxine supply. Hence, the very nature of the tubercle will explain why the part in greatest need of antitoxine must be the last to receive its benefit. Hence, the isolated nature of tubercles and the fortification of bacilli within them to a great degree explain why a much longer time is necessary to bring about results from antitoxine treatment in tuberculosis than in diseases in which such conditions do not exist.

(b) On the other hand, able experimenters have demonstrated that the virulence of the germ is by no means uniform or constant; and, furthermore, that the virulence of the germ is measured by the potency of its toxins. The question then arises, What conditions govern this potency? Does the potency of the toxine depend upon a strong germ, does it depend upon a fertile soil, or does it depend upon both?

I believe the same biological law holds good with germs as with cells; if they are poorly nourished their metabolic power will be less potent. We know that media congenial to the animal cell are uncongenial to bacilli, and inversely. In other words, bacilli thrive best in feeble or pathologic tissues, while normal tissues are more or less uncongenial media. Hence we infer that bacilli necessarily find it more difficult to propagate and colonize in uncongenial media. Therefore, I believe we may safely conclude that as the tissues of the patient approach the normal state, the conditions become less congenial for bacilli, and hence their toxins become less potent and the bacilli less virulent. This hypothesis will account for the fact that bacilli are often found in the tissues of persons apparently in perfect health without producing tuberculosis.

(c) This state has been designated as latency of the germs; but it appears to me that the foregoing explanation is more plausible—that as the culture media become less congenial the toxins are rendered less potent, and as the toxins become less potent the bacilli become less virulent. Therefore, when bacilli are surrounded by the conditions existing within certain animals or within certain persons, such germs, for the time being, really become nonpathogenic.

On the other hand, we must remember that the toxicity of the tubercle bacillus is not its greatest source of danger. It differs from the Klebs-Loeffler bacillus of diphtheria in this respect. The latter possesses a very potent toxine, in which lies its greatest danger. Tubercle bacilli irritate tissue cells and cause rapid cell proliferation, which ultimately forms the tubercle. These neoplasms interfere with the blood supply and nutrition of the adjacent parts. The result is cell and tissue disintegration. But we must also remember that the irritation produced by bacilli is maintained as long as the conditions remain favorable to their growth. Hence,

the first step toward overcoming this condition must be toward increasing the resisting power of the unaffected tissues, and thereby rendering them uncongenial to the germs. By preventing a further extension of the disease we shut off the greatest source of danger.

When tubercles exist bacilli possess strongholds that are very difficult to attack. The tubercle already existing must necessarily, sooner or later, undergo disintegration. Our method of attack must therefore resemble that of a siege. If we render the unaffected parts of the body sufficiently uncongenial so that bacilli are unable to establish new foci, and if the supply of nutrition is shut off from the tubercle and the nutrition within the tubercle itself is utilized, the propagation and colonization of bacilli must cease. The bacilli must therefore either become encapsulated and remain within the body, or pass from the body with the disintegrating parts of the tubercle and the adjacent tissues which have suffered in common with the tubercle itself, or establish themselves in some other part of the body.

Let us now attempt to apply these interpretations to the foregoing cases as affected by the serum treatment. I have observed that all the body functions of patients have distinctly increased under the administration of the serum—the appetite, digestion, sleep, weight, and strength. Also, as the improvement advances, the percentage of young cells of the blood increases. These phenomena are evidently significant of an increased cell activity and constructive metabolism. On the other hand, as these conditions have been observed, I have also observed another set of phenomena. The expectoration in well-established cases increased in quantity, the cough became looser and easier, and the bacilli in the sputum became more numerous. Also, the area of infiltration and consolidation diminished, and the breathing capacity correspondingly increased. I have also observed that as the first set of phenomena increased, the second set increased up to a certain point and then rapidly ceased. I refer particularly to Case I of Class II, and Case I of Class III.

In the majority of the cases in the foregoing report the serum was not continued sufficiently long to bring about a cure. But in these cases good effects were obtained and have been maintained, although a cure was not produced.

Reactions and Physiological Effects.—As is the case with many of the remedies used in the therapy of tuberculosis, the serum does not impair the appetite and digestion. During the course of treatment it produces a depressing effect. The majority of patients begin to experience this about the close of the first week of treatment. The same results may also be experienced at any time during the treatment when the dose has been close to the maximum during several consecutive days. When this effect is produced the dose should be lessened for a short time, and then again slowly increased. If the

serum is administered during the afternoon or evening the slow reaction which occurs a few hours later is experienced at night when the patient is asleep.

Patients undergoing treatment should exercise as little as possible. Rest, lung gymnastics, sleep, and forced nutrition are excellent adjuncts to the serum. I am inclined to believe that a medium dose administered daily over a long period will give better results than if the dose is pushed too rapidly. I have observed that large doses of serum, continued for considerable time in cases with advanced tuberculosis, raise the temperature.

Frequently more or less infiltration is produced about the seat of the injections, but this rarely reaches actual inflammation.

In four cases I have observed distinct evidence of an increased functional activity of the skin. In these cases a distinct morbid condition of the skin had existed years previously. These were generally forms of severe acne. Improvement commenced soon after beginning the serum, and the eruptions finally disappeared.

Instantaneous reactions are occasionally experienced, and are generally the result of a prolonged series of injections in the same area. When they occur, it is generally in persons with tightly contracted skins or in whom there is a deficiency of subcutaneous cellular tissue. The resistance to the injected serum in such persons is greater, and frequently causes much infiltration or induration of the injected area. When the serum is injected in such places, the tissues being non-elastic, the capillaries are readily ruptured and the serum quickly enters the circulation. This evidently is the most important, and often causes more alarm than any other phenomenon in the administration of the serum. A study of these reactions has convinced me that they are not an indication for alarm or for a reduction in the dose, but rather indicate the selection of a new site for administering the serum.

In conclusion, I wish to record the following observations: (1) In incipient cases, or in cases with small areas of infection, the serum treatment gives the best results. (2) Patients with well-established tuberculous lesions require longer time to bring about a cure than has heretofore been considered necessary. (3) A serious mistake is made in dispensing with the use of the serum too soon in any case that improves under its use. I therefore make it a rule to continue the treatment two or three months after all bacilli and other symptoms of the disease have disappeared. (4) I have observed that all patients who have done well under the serum have continued to improve after discontinuing the treatment. This fact would indicate that the effect of the serum is permanent; that it does not simply act while it is being used, but increases the antitoxine-generating power of leucocytes and tissue cells of the patient to such a degree that the artificial supply can be dispensed

with. (5) The number of bacilli in the sputum, when other signs of the disease are diminishing, is by no means a true criterion of the condition of the patient. This has been well shown in each well-established case in which I have observed improvement under the serum treatment. I have observed in a number of cases, just before the complete disappearance of the bacilli, that the sputum was almost a pure culture, the stained film showing bacilli in enormous numbers, frequently in large masses too numerous to count. (6) I have continued the serum in daily doses as long as nine months in individual cases with no deleterious effects. (7) The longer I use the serum the more I am impressed with the necessity of a proper selection of cases. The results obtained from the serum offer no grounds for believing that all tuberculous patients can be cured, or even benefited by it. Yet, notwithstanding the warnings that have been given on this point, reports have been published in which cases of the worst type only were studied—cases of long standing, in last stages, with mixed infection; and, to make such a report even less valuable, the duration of treatment, as shown by the report, ranged from a few days to two months and a half. Unfavorable results naturally followed, and by the same reasoning the treatment was condemned.

Such criticisms have been made against this method of treatment, and indirect reference made to my former report. I refer particularly to Dr. Waxham's paper, *Journal of the American Medical Association*, March 19, 1898, and April 9, 1898. My delay in replying to Dr. Waxham's criticisms has been for the purpose of accumulating more data and gaining a more extended experience. I now feel that I can speak with some degree of confidence, and refer to the foregoing cases as my reply.

I am convinced, after making the foregoing observations, that a failure to obtain satisfactory results in advanced cases does not reflect upon the treatment, but emphasizes the importance of a proper selection of cases and the necessity of beginning treatment early. (8) I wish also to protest against the exaggerated statements so often made for *climate* alone as a therapeutic agent in tuberculosis. Such statements have created a false impression in the minds of physicians living at some distance from Colorado, and especially is this true when they emanate from men who have attained prominence in this field of work.

It is a well-recognized fact, especially in Colorado, that the great majority of tuberculous patients sent to us from other parts of the country come with the understanding that *climate* alone will give the beneficial results desired. I have given particular attention to this point in the study of the foregoing cases. It is true that many of the patients improve, but if they are carefully followed it will be observed that in a large percentage the improvement is temporary or incomplete,

and that sooner or later a relapse occurs. Hence, many of these patients, in a short time recognizing this truth, realize that they require more than *climate*. They feel the need of counsel, and, naturally turning to an expert on "*climate*," in a short time find themselves under his care. As the disease insidiously makes progress, the patient receives the final information that *climate* was sought too late, and is ordered to his former home. In this manner many physicians at a distance have already learned that the statements regarding *climate* alone proving beneficial in tuberculosis have been misleading.

I would not be understood as opposing properly selected climates in the treatment of tuberculosis. I maintain, however, that erroneous impressions have been given to those who have had no opportunity to investigate this question for themselves. Any well-informed physician, and even the well-informed laity will recognize as self-evident that more than *climate* is necessary to bring about successful results in these cases. Proper tissue nutrition and aids to cell metabolism are essential points which can not be neglected in the successful treatment of tuberculosis.

It has been my experience that there are few diseases which require more careful, conscientious, and earnest advice than tuberculosis, even when the patients have the advantage of living in the Colorado climate. The climate in many cases, aided by a rest from cares and former labors, often checks the active processes of the disease and causes it to remain in a quiescent state. In many cases, however, this latent state is misinterpreted as a cure, and not until the patients return to their former homes do they realize their error, when the disease shows evidence of renewed activity.

Very few patients will persistently follow any treatment daily during a period of six or nine months, unless they believe it their last resort. Even then it requires not a little confidence on the part of the patients, both in the treatment and the physician administering it; otherwise, periods of despondency will come, with a strong tendency to abandon the treatment.

We are all inclined to be dissatisfied with slow progress. But in a disease so unyielding as tuberculosis any treatment that offers the hopes that seem to be presented by serum therapy is worthy our most serious consideration. I have, however, found from experience that patients will become reconciled to their condition in a short time after they are informed of their actual condition, and will cooperate with the physician who is thus candid with them to a greater degree than if left in doubt as to the nature and extent of their disease.

In presenting this report I have endeavored to give the unfavorable as well as the favorable points observed—the disappointments as well as the hopes inspired. After sixteen months of constant study of the effects of the "*antiphthasic serum, T. R.*" I am impressed with

the belief that serum therapy is the coming therapy for tuberculosis.

NOTE.—Three months having passed since completing the foregoing report, I have thought it advisable to give a brief statement of the condition of the patients up to date (April 1, 1899).

Class I.—No relapse has occurred in any member belonging to this class since January 1, 1899. Of the three patients who were taking the serum on January 1, 1899 (Cases 4, 10, and 12), two are continuing the treatment, and are making distinct progress (Cases 4 and 12). One patient (Case 10) has been discharged. Two "O. T." tests were used, 1 mg. and 5 mg. respectively, with no reaction. It should be remembered that this patient reacted distinctly to 1 mg. previous to commencing the use of the serum.

Class II.—There has been no relapse. In Cases 1 and 2 both the patients continue well. In Case 3 the patient has not resumed treatment. The disease remains apparently stationary. There has been no relapse.

Case 4. I have had no communication from this patient since completing the report. **Case 5.** The patient has continued to improve. He weighs more than ever before, but bacilli continue. He has been in New Orleans until recently; has wished to continue the use of serum, but has been unable to find a physician who would administer it. He has recently gone to Texas, and has now resumed the use of the serum and expects to continue its employment until the bacilli disappear.

Cases 6 and 7. Both patients continue the use of the serum, with distinct improvement.

Class III.—Three patients in this class have suffered severely from the gripe (Cases 1, 3, and 4); two of them are rapidly convalescing (Cases 1 and 4); one is convalescing very slowly (Case 3). No deaths.

Class IV.—As has been shown by the report, none of the patients in this class were under treatment January 1st; the majority having failed to improve beyond a certain point, the use of the serum was discontinued and they returned to their homes. It is important to note, however, that, so far as I have been able to ascertain, there have been no deaths in this class since the report was completed.

205, 206 JACKSON BLOCK.

THORACOPLASTY FOR SARCOMA OF THE CHEST WALL.

By FRANK HARTLEY, M. D.,
ATTENDING SURGEON, NEW YORK HOSPITAL.

THE case I wish to report was operated upon by me in 1895, and, though I am not usually in favor of reporting old cases, I think this one demands such a report. Operative procedures for malignant disease with an immediate happy result are frequently reported, but we find that a small percentage of these have a permanent freedom from recurrence. Tumors involving primarily the soft parts of the thoracic wall, such as subfascial lipomata, submuscular fibromata, angiomiata, or lymphangiomiata, with prolongations between and beneath the ribs in the subpleural space, are in the first place rare and, secondly, do not usually require more than a simple resection of the rib or ribs for their complete removal. With tumors of the bony framework, however, the condition is quite a different one, and we must be prepared at all times to enter the pleural cavity in order to secure a successful result. I refer here particularly to the enchondromata and sarcomata. Enchondromata in this region are not common, since in

two hundred and thirty-seven cases Weber found only seven, while Gürtl found only three cases, and Schläpfer in the whole literature of the subject found only twenty-eight cases involving the ribs. A precise and reliable collection of the enchondromata is a difficult task, owing to the mixed forms of tumor formation which occur in this region and in which cartilage is present as a purely transitional tissue with other varieties of growth, as well as to the varied applications given to the same growth by different pathologists. The enchondromata, occurring usually as single tumors and in the immediate neighborhood of the cartilage of the rib, exhibit a slow, continuous growth in size and, according to their location, a greater or lesser amount of disturbance from pressure or weight. Severe symptoms are exceptionally present, even though the growth into the subpleural space causes an irritative pleuritis or compression of the lung. Fortunately, in the cases so far reported the pleuritis has not been attended with an extensive fluid exudate, nor has the compression of the lung been such as to render it impossible for the lung to accommodate itself to the pressure. In a very few cases the growth of the tumor has ceased after several years (twenty-five to thirty) of increase. It is the rule, however, to observe a slow but steady increase in size, which after years shows a distinct malignancy in its rapidity of growth and metastases. Primary sarcoma of the tissues over the ribs and periosteum is rare, although such cases are reported by Waitz, Billroth, Küsler, Lievier, and Falkson. It is not rare, however, for a primary sarcoma to take its origin in the bony framework, either of the sternum or the ribs, in the form of a periosteal or endosteal growth.

Pulmonary involvement as a general rule takes place late in the course of the tumor's existence, and in many cases this fails to be present at all. Nor does the process advance so rapidly that the lung can not accommodate itself for a time at least to the infiltration or the pressure of the tumor alone, or to the pressure of the pleuritic exudate (sarcomatous pleuritis). Sarcomata occur more frequently in the sternum, while the enchondromata seem to have a greater predilection for the ribs.

Sarcomata and enchondromata have been removed by thoracoplastic operations, together with a larger or smaller portion of the costal and diaphragmatic pleura, in seventeen instances (Paget, 1897). Of the seventeen, four died of or after the operation; one recovered from the operation, but died quickly of recurrences; twelve made a complete recovery. The mortality from the operation was therefore 23.5 per cent. Slow recovery and death from recurrence and septic infection, 5.9 per cent. Complete recovery from operation, 70.6 per cent. Those cases in which the pleural cavity was not opened were (Paget) six in number. Of these, two died. The mortality was therefore 33⅓ per cent. Recoveries, 66⅔ per cent.

Schläpfer's statistics include sixteen cases of en-

chondromata which were removed. Eight cases resulted fatally. Two of these died of metastases in the lungs, two of pneumothorax, two of local recurrences, one of morasmus, and one of pleuritis (?). Schläpfer also collected twelve cases in which no operation was performed. Of these patients, eleven died. Gerulanos has collected thirty-eight cases of tumors of the thoracic wall in which thoracoplasty has been done. In these thirty-eight cases, thirteen of the patients died—three of collapse within eight to twenty-four hours after operation; two with no statement of time or cause; one with no statement of cause on the fifth day; one of empyema with perforation of the lung at three months; one of carbolic poisoning at three months; one of oedema of the lungs, hæmorrhages into the pleura and pericardium, at the end of the second day; one of capillary bronchitis without infection of the pleural cavity, time not stated; one of metastases in the right lung with a large serous and bloody exudate upon the left side, operation upon the right side; died on sixth day; one of tuberculosis pulmonum on the fifth day; one of pneumothorax on the second day—mortality is 34.21 per cent. Of these thirteen cases, we find three with no statement of the cause of death. Of the ten remaining patients, three died of collapse, one died of carbolic-acid poisoning, one died of pneumothorax, and the remaining of complications on the part of the lungs. We have therefore four cases as the direct result of the operation (11.4 per cent.), and if the three cases of which nothing is known as to the cause of death are here included, 18.4 per cent. Adhesions to the thoracic wall and diaphragm, together with extensive involvement of the lung itself, may be present without giving symptoms or physical signs denoting their presence, and the surgeon must be prepared in any case to open the pleural cavity to remove a larger or smaller portion of the thoracic wall and to deal with hæmorrhage from the thoracic wall and lungs (case of Gerulanos, *Deutsche Zeitschrift für Chirurgie*, 1898, Bd. xlix).

The mortality of this procedure has been largely due to operations performed upon cases in which the diagnosis of the interpulmonary condition has not been accurately made out. The enchondromata demand as early a removal as the sarcomata, and delay in a sufficiently thorough removal at the outset allows only a greater chance for a recurrence.

In the smaller tumors of this class a complete and thorough extirpation can often be accomplished with a resection of the ribs alone. In the larger and more rapidly growing tumors one must add to this resection of the ribs the danger resulting from a pneumothorax, an infection of the pleural cavity, and hæmorrhage from the lungs when they are involved.

Operators are in the main agreed that the incisions exposing the tumor should fashion a flap which will cover its site. A resection of the ribs should follow the exposure of the tumor. They should be divided at

some distance from the growth, and after ligation of the intercostal arteries the tumor, together with the ribs, should be raised and a separation of the costal pleura from them be accomplished. When this is not feasible, owing to involvement of this membrane, the pleural cavity is opened and as much of the membrane as is necessary is removed. After removal of the tumor and ribs, the borders of the wound are to be accurately sutured, for the more precise and exact this suturing of the borders of the pleura and thorax, the more quickly disappears the pneumothorax. An exact arrest of all hæmorrhage before the pleural cavity is opened and before the final suturing is accomplished is all-important.

In the abdomen we have to combat principally infection, whereas in the thorax we have in addition mechanical conditions to avoid which are scarcely as yet overcome with certainty. Though a traumatic pneumothorax is relatively well borne, and large blood extravasations in the pleural cavity are absorbed, patients have not infrequently succumbed to the first attack of shock or compression of the lung, becoming dyspnoic and dying of asphyxia.

The smaller the opening in the pleura—i. e., the smaller in proportion to the diameter of the bronchus—the more the lung is able to maintain its function. The larger this opening, the more rapidly its collapse in proportion to its elasticity. By each inspiration a diminished volume of air space is left. The mediastinum is pushed to the healthy side, and hence an increased blood pressure. The surface of the lung is cooled and the terminal filaments of the vagus are irritated.

This sudden change in the conditions within the thorax will cause a severe alteration in the action of the heart and lungs:

1. An increased frequency in respiration, with the lung upon the operated side in a state of collapse.

2. Owing to pushing of the mediastinum toward the non-operated side and the depression of the diaphragm (the result of atmospheric pressure), the lung upon the uninjured side is compromised in its inspiratory effort, and the heart and greater vessels within the mediastinum may completely stop action. This is induced partly by direct action and partly by reflex action through the vagus.

3. When the opening in the thorax is of sufficient size and is left open a long time owing to the same causes, an increased frequency in heart action and in respiration takes place which may go on to cessation of action. With closure of the opening in the thoracic wall the air is absorbed and the symptoms are relieved slightly immediately after operation, in greater degree in thirty hours, and in some cases the air has been completely absorbed in three days. Then, we should allow the air to enter the pleural cavity slowly, and should finish all work that can be done before opening the cavity, so that as much time as possible may be saved in ex-

posing the lung and mediastinum to the atmospheric pressure.

Care must also be taken to prevent the cooling of the surface of the lung by warm and moist compresses.

When the tissues over the tumor are involved so that they can not be retained for a flap, it is thought best to cover the space with sterilized rubber tissue, securely fastened to the margin of the wound. It should remain until the lung expands and becomes adherent to the margin of the space left in the thoracic wall. Or we may make use of the occlusive dressing, and secure drainage by an opening which is relatively smaller than the diameter of the bronchus—i. e., by gauze packing, occlusive dressing, and tube, which remain in place until adhesion occurs to the margin of the space excised. Where this is done, the lung will expand often within three to seven days.

It should also be remembered that a difference exists in the danger of the operation as to whether the right or left side is the site of procedure, since the increased danger in operating upon the right thorax depends upon the air pressure upon the right auricle and vena cava interfering thus with the proper aspiration of venous blood. While we can remove portions of the thoracic wall without great danger and allow the production of a traumatic pneumothorax, the surgery of the lung has not advanced *pari passu*. Tumors of the thoracic wall may, however, extend to the lung and demand partial or complete extirpation of one or more lobes. Weinlechner was the first, in 1880, to operate for this condition, and since then Krönlein, Heinicke, Koenig, Park, Muller, Hilferich, and Gerulanos have each performed the operation. Of these eight patients, four died; two died early of a pleuritis, while two died of exhaustion due to heart failure. The possibility of easily overcoming the hæmorrhage in the lung where a partial resection of a lobe is done is exemplified in these cases. The procedures most in favor seem to be either the tamponade with gauze or the ligature *en masse* (*Umschlingsnaht*) in cases of a partial resection, while in the complete extirpation of a lobe both Hilferich and Gerulanos arrested the hæmorrhage perfectly by the use of a clamp and catgut ligatures applied at the hilus of the lung. The blood pressure in the pulmonary arteries being one third less than in the general circulation, the application of ligatures to the arteries may be made as easily as to veins. With the dangers of hæmorrhage and sepsis reduced to a minimum, we have left the severity of the operation itself as the main point to combat.

CASE.—M. B., aged ten years and a half, born in New York State, was admitted to the hospital on September 5, 1895.

On June 10, 1894, the patient had been operated upon for a fibrosarcoma of the chest wall, at which time the tumor was removed without a resection of the ribs to which it was probably attached. A reappearance of the growth took place within six weeks from the time of the operation.

At the present time (three months from the time of operation) the neoplasm is situated just below the axilla of the left side and over the fourth, fifth, and sixth ribs and the intercostal spaces. It is quite painful and is closely attached to the ribs over which it lies. There is no history of pulmonary complications. The mass has been noticed by the patient for about six weeks. Physical examination shows the tumor to be hard and evenly outlined. It measures three and a half by four inches. It is situated between the anterior and posterior axillary lines and occupies the space over the fourth, fifth, and sixth ribs and their intercostal spaces. It is immovably attached to the ribs mentioned. The skin over the tumor is freely movable and is uninvolved by the growth. An examination of the chest and of the abdomen was negative. The urinary examination was also negative. The temperature and pulse were normal.

Operation, September 27, 1895.

Ether. An incision (tongue-shaped) beginning at the lower border of the second rib in the posterior axillary line was carried downward to the lower border of the seventh rib, thence forward along this rib until the anterior axillary line was reached, whence it ascended to the lower border of the second rib. This flap, which exposed the space over the third, fourth, fifth, sixth, and seventh ribs, was dissected from the underlying tissue. A circular portion of the chest wall was removed, including the growth and about an inch of healthy tissue beyond its edge, after separating the periosteum of the fourth, fifth, sixth, and seventh ribs and securing the intercostal arteries at the point at which they were to be divided. After the division of the ribs the attempt to separate them from the costal pleura revealed an intimate union of the pleura to the growth over a space of two inches and a half by three inches.

The pleura was then incised in a line with the division of the ribs and was removed, together with the ribs and the tumor. The air was allowed to enter slowly into the pleural cavity. The lung collapsed, except for such air as entered it from the right lung. The pulse maintained its usual rate, and no cyanosis nor shock was observed. All hæmorrhage having been stopped, the flap, consisting of muscle, subcutaneous tissue, and skin, was replaced and was carefully sutured to the margin of the opening into the pleural cavity with catgut for the deep sutures and silk for the superficial sutures. The edges of the incision were accurately apposed, except for an inch at the lower margin, where a sterile gauze packing protruded through the opening left beneath the flap. A sterile dressing and a binder were then applied.

September 30th.—Dressing changed. It is soaked with a clear fluid slightly tinged with blood. Temperature, 104° F.; pulse, 110.

October 1st.—Temperature and pulse normal. Wound closing nicely.

October 3d.—Temperature and pulse normal.

October 5th.—Stitches removed. Dressing reapplied.

October 7th.—A considerable amount of clear fluid discharged from the wound. Dressing reapplied.

October 7th, 9th, and 16th.—Wound healing. Dressing reapplied. Temperature and pulse normal.

October 30th.—A small sinus only remains. Examination of the chest reveals nothing abnormal except some adhesions beneath the area of operation.

October 31st.—Discharged.

November 10th.—A communication from the patient's physician states that the sinus remaining after leaving the hospital has closed.

Pathologist's Report of the Tumor.—A hard, white, fibrous tumor attached to the periosteum of the fourth, fifth, and sixth ribs. It involves the pleura covering its internal surface. Microscopically it is a somewhat vascular, round and spindle-celled sarcoma.

January 14, 1898.—The patient informs me by letter that she is in good health and free from any return of the tumor.

January 10, 1899.—I am informed by her physician that she is still free from any recurrence; that no lateral curvature in the spine is present; the thorax shows but little deformity in shape, considering the amount removed; and that the lung seems to perform its functions in a perfect manner.

From the examination of this and other cases of thoracoplastic operations for neoplasms involving the chest wall, it is evident that much of our success will depend:

1. Upon an early accurate diagnosis and thorough and complete removal of the growth.

2. Upon the fact that the shock following these operations is usually not severe and can be overcome.

3. Upon the fact that hæmorrhage, when confined to the area supplied by the intercostals and the internal mammary arteries, can be safely and easily avoided, and when the process has extended to the lung, requiring either a partial resection or an extirpation of a lobe, loss of blood has been minimal through the use of the clamp, ligature, and packing.

4. Upon the fact that, though a traumatic pneumothorax has been considered a barrier to these operations, yet in a normal condition of the pulmonary organs, provided air is not admitted to the chest cavity through a valvular orifice, the pressure does not seem to be sufficient to cause any alarm. With a free and more or less extensive opening in the chest wall, the lung collapses during two or three respirations and remains so except for such air as is forced into it from the lung of the opposite side during expiration. This is especially observed during the time in which any obstruction to respiration exists in the upper air-passages.

5. Upon the fact that though the infection of the pleural cavity seems to be the greatest danger, a danger which may involve not only the pleural cavity of the side operated upon but as well of that of the opposite side, yet with care even this complication has been successfully avoided.

6. Upon the time of exposure of the lung to the pressure and the cooling effects of the air, which may in a great measure be curtailed by attention to all hæmorrhage before opening the cavity, and, after opening it, by the use of warm and moist gauze pads.

7. Upon the fact that flaps are fashioned so as to cover the defect in the thorax when possible, otherwise the use of rubber tissue packing and an occlusive dressing.

8. Upon the use of drainage, which seems so far to have been employed in all the successful cases.

A STUDY OF PRESENTATIONS AND POSITIONS OF THE FÆTUS.

By ELIZA H. ROOT, M.D.,

CHICAGO,
PROFESSOR OF OBSTETRICS
IN THE NORTHWESTERN UNIVERSITY WOMAN'S MEDICAL SCHOOL.

IN 1771, Solayrès, of Paris, wrote his essay, *Dissertatio de partu viribus maternis absoluto*. This essay marks an epoch in the history of obstetric art. In it the author discusses presentations and positions, and classifies them for the first time. Baudeloque, a pupil of Solayrès, closely followed his young master with a classification too complex and confusing to be practical. He was followed by others with classifications aiming at greater simplicity. All obstetricians have been agreed, since the time of Solayrès and Baudeloque, upon the two cardinal positions right and left, and in the main upon the fixed points of reference upon the foetal head.

But the landmarks upon the maternal pelvis were arbitrarily chosen, each authority selecting his own.

The nomenclature employed was wanting in uniformity, was confusing to the beginner, and proved troublesome to the practised student. Since the relation of certain landmarks of the presenting part must, in fact, sustain a fixed and uniform relation to certain landmarks of the pelvic inlet, it is unfortunate that so much confusion existed for so long.

Left occipito-anterior is and has always been left occipito-anterior. It is identical with left occipitotilia, left occipito-acetabular, left occipito-cotyloid, and first oblique. This variance in naming the points of the pelvis extends to all the different vertex, face, breech, and trunk positions. It extends also, to a greater or less degree, to the fixed points of the presenting breech and trunk of the foetus. Again, the relative frequency of the positions caused them to be named by numbers. Comparing a copy of William H. Byford (edition 1873) with one of Playfair (edition 1876), we find the second and third positions of Playfair differ from the second and third of Byford. Each author is, doubtless, correct according to his own observations or his teachings, but the numbering of the positions by individual observers gave rise to confusion, for no two observers will or can arrive at the same conclusions in matters requiring mathematical exactness, and for obvious reasons.

The confusion attending the student beginning the study of obstetrics with Playfair for text book and Byford for didactic teacher, or vice versa, is very apparent. And yet this was the state of teaching enjoyed (?) by many who are still in active practice. Charpentier, Tarnier and Cazeau, and Playfair, of Europe, Dewees, Meigs, and Byford, of America, are authors of ability

and men of broad experience that appeared since 1871, the year that marks the first century milestone from the classification of Solayrès. A study of these authors reveals that efforts to simplify matters up to this time had met with poor success. Each one differs from the other. Since 1864, when abdominal palpation came into general use as the best method of diagnosis, the tendency has been to make classification and nomenclature more simple. But, in the absence of a fixed standard, individual effort contributed to the continuance of the confusion rather than to its removal. It was very apparent to the best teachers that a uniform nomenclature in obstetrics could be obtained only by a concerted effort, based upon a nomenclature generally agreed upon.

As the time seemed ripe for action, Dr. Alexander Russell Simpson, of Edinburgh University, brought the subject before the Seventh International Congress, held in London. At this meeting a committee, international in *personnel*, was appointed, to draw up a scheme for a common obstetric nomenclature.

Each member of the committee was to consult with a committee of his countrymen. At the next meeting, held in Copenhagen, "a scheme for recommendation" was adopted. This scheme was sent to all the leading obstetricians of the different civilized countries. Criticisms and suggestions were invited in order to secure a full representation upon which the committee might base its report. For presentations and positions we find the following: "The positions of the fetus are best named, topographically, according as the denominator looks—first, to the right or left, and second, anterior and posterior. The Latin words should be used, and when initial letters are employed it is advisable to use the initials of the Latin words" (1).

At the next and ninth International Medical Congress, held at Washington, D. C., 1887, Dr. Simpson made an analytical report, drawn up from replies received to the recommended scheme. The report was received, and the committee (2) instructed to formulate a classification and nomenclature to be presented at this same meeting. The formulated scheme was drawn up accordingly, and presented to the Section on Gynecology and Obstetrics. After considerable discussion, none of which was very unfavorable, the report was adopted. It was chiefly due to the energy and persistence of Dr. Simpson that the measure was carried, a measure that has rendered the teacher and student of to-day a signal service.

I here transcribe the classification of positions as adopted at this meeting:

Left occipito-anterior = occipito-lavo-anterior = O. L. A.

Left occipito-posterior = occipito-lavo-posterior = O. L. P.

Right occipito-posterior = occipito-dextro-posterior = O. D. P.

Right occipito-anterior = occipito-dextro-anterior = O. D. A.

Sacro can be substituted for occipito, and S. for O. for breech presentations; for shoulder presentations, scapulo can be substituted for occipito, and Sc. for O.; for face and brow, "mento" can be substituted for occipito, and M. for O., and the table is complete. Presentations are not named, being understood by implication. This formula is adopted by the *American Text-book of Obstetrics*, as becomes an American book, and is otherwise in general use. The variations now consist in the order of the initials and in the use of the English instead of the Latin for right, R. displacing D. in the initials. For the practitioner who is familiar with his subject, the abbreviations and the words they represent are sufficient. But for the student, to whom we teach presentation and position by means of abdominal palpation, the formula requires the addition of the implied presentations.

For my own classes I have found the method or scheme employed in the German schools useful, and present it as follows: There are but twolies (3): left or first, right or second. Left and right refer to the sides of the mother, and the lie of the fetus is determined by the side of the mother toward which the fetal back looks, or in which it lies, for vertical or longitudinal lies (presentations), and the fetal head fixes the cross lie (transverse presentation).

If the head is in the mother's left iliac fossa or flank and the breech in the opposite iliac fossa, it is a left or first cross lie, etc. In the vertical lie one or the other pole of the fetus must present at the pelvic inlet, while in cross lie some portion of the trunk must present.

The position anterior and posterior of the presenting part is determined by the direction of the back of the fetus. If the back looks toward the front of the mother, approaching the median or long axial line of the uterus, the position is anterior; if the back is carried away from the median line of the mother's abdomen and is directed more toward her back, the position is posterior. This plan, when formulated, reads thus:

Left or first lie	{	Vertex	{ Occiput anterior = L. O. A.
			{ Occiput posterior = L. O. P.
	{	Breech	{ Sacrum anterior = L. S. A.
			{ Sacrum posterior = L. S. P.
Right or second lie	{	Vertex	{ Occiput anterior = R. O. A.
			{ Occiput posterior = R. O. P.
	{	Breech	{ Sacrum anterior = R. S. A.
			{ Sacrum posterior = R. S. P.

Left or first cross lie, back anterior or posterior.

Right or second cross lie, back anterior or posterior.

For the varieties of head presentation, as face or brow, mentum can be substituted for occipito and M. for O. In a cross lie (transverse presentation), the part of the trunk presenting, usually the shoulder, can be determined by the side of the mother in which the head lies and the relation of the fetal back to her abdominal wall. The direction of the back and the side of the mother

in which the head lies, when known, the shoulder presenting is readily determined. Practically, it makes but little difference what part of the trunk presents, for the cross lie must be converted by version into a vertical lie before delivery can take place with safety to mother and child. To make the work thus presented clearer to the student mind we divide it into steps.

First Step.—Find the fetal back; distinguish the firm, smooth plane of the back on one side from the uneven surface of the opposite side and in which will be found the movable small parts of the fetus and the space filled with amniotic fluid. In cases of hydramnios only the amniotic-fluid-filled space can be felt unless the fetus moves its limbs forcibly under the palpating hand.

Second Step.—Find the head of the fetus, differentiating it from the opposite pole.

Third Step.—For position of the presenting part, determine the relation of the fetal back to the median line of the mother's abdomen in a vertical lie, and in a cross lie determine the relation of the back of the fetus to the abdominal wall of the mother in the transverse axis of the uterus.

These steps well fixed in the mind of the student, he reads the initials L. O. A., R. O. P., etc., understandingly. To him L. and R. indicate the lie of the fetus; O. and S. indicate the presentation, and A. and P. tell him in which quadrant of the pelvic inlet the fixed point of the presenting part lies, or toward which it is directed.

The varieties that occur in presentation and position must not be overlooked. First: Varieties occurring in the lie of the fetus.

(a) In a vertical lie the long axis of the fetus crosses the long axis of the uterus at an acute angle, and may be named in the diagnosis, left or first head-lie oblique and second or right head-lie oblique. In a breech-lie this obliquity has but little significance, for it usually exists, the breech never engaging until labor begins; indeed, the oblique lie may serve as an aid to a correct diagnosis of breech-lie. But in a head-lie it is significant, for it always indicates some existing disproportion between the fetus and the maternal parts that exerts a more or less important influence upon labor and its prognosis. The cause of the obliquity in the head-lie may rest with the maternal parts, as in cases of hydramnios, (a common cause), a contracted inlet, or a flat pelvis. It may rest with the fetus, that may be too large to enter a normal pelvic inlet; or the fetus may be too small to engage. In multiple pregnancy the anterior fetus may rest in the oblique lie. The natural forces of labor in its early stage may convert an oblique lie into a cross lie. This accident is especially liable to occur in hydramnios, narrow inlet, or in the presence of a pelvic tumor. Some authors call a cross-lie an oblique lie. It is gratifying to find that Dr. Hirst and Dr. Grandin and Dr. Jarmin separate the oblique lie from the cross or transverse lie, and emphasize its importance.

(b) In a cross lie any part of the trunk may present—

back, abdomen, shoulder, scapula, or gridiron. As version must correct the cross lie, the part presenting plays no important part in the mechanism of delivery.

Second: Varieties in the position of the presenting pole of the fetus.

(a) Head-lie: Extension of the chin, producing face or brow presentations; transverse positions of the head—i. e., the long diameter of the head engages in the transverse diameter of the inlet or parietal bone posterior with the plane of the biparietal diameter of the head oblique to the plane of the inlet—Nägele's obliquity. Auvard, of Paris, in a late American edition of his work, treats the transverse position of the head as anomalous, likely to occur in large or flattened pelves. But he includes it in his tabulated formula, in which he still adheres to the old plan of eight positions for the vertex. Other and very recent authors treat the transverse diameters of the head as anomalous, but do not enumerate them with the four cardinal positions now in general use. Clinical experience teaches the later to be more in accordance with the truth and with simplicity.

(b) Varieties of breech-lie: Complete breech-lie, the more favorable and typical; incomplete breech-lie, the more unfavorable and atypical. In the complete breech, the sacrum or nates present, the thighs are flexed upon the trunk, the legs upon the thighs, the feet crossed and presenting with the nates. In the incomplete, sacrum or nates present, but the limbs are extended so as to lie parallel with the abdomen of the child, the feet resting near the chin, or one foot on each side of the neck. When both limbs are thus extended the labor is difficult and tedious, especially in primiparae, and the child's life is placed in jeopardy.

Therapeutical Notes.

A Mixture for Anorexia.—We find the following in the *Progrès médical* for March 4th:

R Tincture of gentian, |
Tincture of columba, |
Tincture of star-anise, } equal parts.
Tincture of nux vomica, |

M. Ten drops to be taken before each meal, in a little water.

Treatment of Brittle Nails. Dr. N. S. Telf (Medical Brief, April), in answer to a correspondent's query, says that for many years he has recommended the use of lemon juice. He recommends the keeping of half a lemon on the washstand and directs that every time the person washes he should put each finger into the

lemon and use as little soap as possible. The lemon, he says, neutralizes the alkali and will restore the nails in a week.

An Ointment for Sciatica.—The *Riforma medica* for February 18th gives the following formula:

℞ Oil of turpentine, } each	5 parts;
Oil of gelsemium, }	
White wax	2 "
Simple ointment	40 "

M. To be applied to the painful part.

A Pill for Dysmenorrhœa, the Menorrhagia of Puberty, and Uterine Atony.—The *Riforma medica* for February 23d gives the following formula:

℞ Iron and ammonium } citrate,	} each ... 1 drachm;
Powdered ergot,	
Extract of kola	a sufficiency.

M. Divide into fifty pills, to be silver-coated. From two to six to be taken daily at the menstrual periods.

An Application for Excessive Sweating of the Hands.—The *Riforma medica* gives this formula:

℞ Boric acid	5 parts;
Borax, }	} each 15 "
Salicylic acid, }	
Glycerin, }	} each 60 "
Dilute alcohol, }	

M. To be rubbed on three times a day.

A Tooth Powder for Children.—Monti's formula is given as follows in the *Dental Review* for March:

℞ Magnesium carbonate	75 grains;
White chalk, }	} each 225 "
Sodium salicylate, }	
Oil of peppermint	6 drops.

M.

A Mouth Wash for Children.—The *Dental Review* for March ascribes the following formula to Monti:

℞ Boric acid	3 parts;
Distilled water	200 "
Tincture of myrrh	2 "

M.

The Treatment of Alveolar Abscess.—Vian is credited in the *Riforma medica* for March 11th with the following formula:

℞ Salol, }	} each 4 parts;
Menthol, }	
Chloroform	3 "
Distilled water	100 "

M. Rinse the mouth with the solution several times a day. Apply the following to the gum of the affected tooth:

℞ Tincture of iodine, }	} each 4 parts;
Tincture of acetonite, }	
Chloroform, }	} each 1 part.
Tincture of benzoin, }	

Lutaud's Pills for Amenorrhœa.—The *Riforma medica* for March 3d gives the formula as follows:

℞ Iron and potassium tartrate	45 grains;
Extract of artemisia, }	} each ... 30 "
Extract of absinthium, }	
Socotrine aloes	15 "
Oil of anise	enough to aromatize.

M. Divide into thirty pills. One to be taken before every meal.

An Application for Pruritus Ani.—We find the following formula in the *Riforma medica* for March 13th:

℞ Sodium hyposulphite	30 parts;
Carbolic acid	5 "
Glycerin	20 "
Distilled water	450 "

M. To be applied on compresses.

An Application for Eczema of the Anus.—Brocq's formula is given as follows in the *Riforma medica* for March 13th:

℞ Rasped camphor	2 parts;
Zinc oxide, }	} each 30 "
Bismuth subnitrate, }	
Powdered tale	40 "

M.

The Treatment of Freckles.—The *Indépendance médicale* for March 15th gives the following as the formula of Hardy's lotion:

℞ Corrosive sublimate	7½ grains;
Zinc sulphate, }	} each 30 "
Lead acetate, }	
Alcohol	a sufficiency;
Distilled water	7,500 grains.

M.

According to the same journal, Leloir advises scrubbing the affected part with green soap and then applying the following solution:

℞ Chrysophanic acid	15 parts;
Chloroform	100 "

M. The part then to be covered with a layer of chloropercha.

An Ointment for Lupus of the Vulva.—The *Riforma medica* for March 3d credits the following formula to Boeck:

℞ Olive oil, }	} each 8 parts;
Rosin, }	
Yellow wax, }	} each 1 part;
Gum ammoniacum, }	
Venice turpentine, }	} each 4 parts.
Pyrogallie acid	

M.

Coffee-flavored Cod-liver Oil.—The *Riforma medica* for March 9th attributes to Patein the following formula:

℞ Cod-liver oil	6,000 grains;
Powdered coffee	300 "
Animal charcoal	150 "

Heat to 140° F. in a covered vessel, allow it to remain for five days from time to time, and strain it.

A Soothing Ointment.—The *Riforma medica* for March 9th attributes the following to Patein:

℞ Benzoated lard	600 grains;
Laudanum	60 "
Chloroform	45 "
Extract of belladonna	30 "
Extract of cicuta	15 "

M.

For external use only.

Gonococcic Rhinitis in an Infant.—H. de Stella (*Belgique médicale*, January 26th; *Indépendance médicale*, March 1st) reports the case of an infant two months old brought to the clinic in consequence of an impediment in nasal respiration existing from birth, and preventing it from taking the breast. Examina-

tion of the pus from the nostrils showed abundant gonococci. The child had previously had purulent ophthalmia, which had only yielded to the most persistent and energetic treatment. There was also otitis media consecutive to the rhinitis. A generalized syphilitic roseola followed. It was found that the father had suffered from syphilis and concurrent gonorrhea and had infected the mother, thus transmitting the diseases to the child.

The treatment of blennorrhagic rhinitis, says the author, is simple. Lermoyez recommends lavage of the nostrils with simple boiled water, and the insufflation into each nostril of a small quantity of the following powder:

℞ Powdered fused silver nitrate. 3 grains;
Talc 150 "

M.

The author has found the following treatment very successful. He paints the nasal fossæ daily with a pledget of absorbent wool saturated in a solution of protargol, one in fifty, or even one in ten, if the infection is virulent. In the intervals he advises the parents to introduce, three times daily, into the child's nostrils the following ointment:

℞ Vaseline 225 grains;
Boric acid 22½ "
Menthol 2½ "

M.

The author finally impresses upon accoucheurs the necessity for as careful prophylactic consideration of the nasal passages in children born of suspected parents as is accorded to the eyes. A thorough disinfection of the nasal fossæ by dropping into them a 1-in-1,000 solution of sublimate, or of protargol 1 in 80, would prevent the development of this terrible evil, which by enforcing mouth breathing fills the lungs with cold air charged with bacteria-laden dust, often eventuating in laryngeal bronchial, and pulmonary affections; and, moreover, by diminishing the bactericidal action of the nasal mucus, lays the system open to secondary infection of all kinds—to say nothing of its essential nature and its extension to the ear.

A Safe and Rapid Method of Removing "Ear Wax."

—The *Western Clinical Recorder* for March says that cerumen may be quickly and effectually softened by filling the meatus with peroxide of hydrogen and allowing it to soak for a few moments, after which it may be easily removed by syringing with warm water.

Cimicifuga in the Treatment of Tinnitus Aurium.

Model and Robin (*Médecine moderne; Therapist*, February 15th) report the successful employment of cimicifuga in cases of tinnitus aurium not dependent on disease of the ear, even when there was a collection of cerumen. The tinnitus usually subsided in the course of three days, but the treatment failed in cases that had lasted for more than two years.

Mercurial Injections in the Treatment of Lupus.

Bernstein (*Münchener medizinische Wochenschrift*, November 15, 1898; *British Medical Journal*, March 11, 1899) has collected the recorded cases of lupus treated with calomel injections. In thirty-seven cases the results were positive, and in ten they were negative. The amount used for each injection was a cubic centimetre of a ten-per-cent. emulsion with olive oil. Six injections were given in eight days.

THE NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, APRIL 8, 1899.

DECAYED TEETH AND TUBERCULOUS CERVICAL GLANDS.

MEDICINE is constantly getting more and more indebted to the dentists for researches that are of distinct value in pathology and often have a direct bearing upon the prevention if not the cure of serious disease. The latest instance that has come to our notice is an investigation of the connection between decayed teeth and the occurrence of tuberculous infection of the lymphatic glands of the neck, by Dr. George W. Cook, of Chicago (*Dental Review*, February). Dr. Cook says that the idea that the pulp canals of decaying teeth might be the channels for tuberculous infection of the cervical glands was advanced some years ago by Dr. Stanley P. Black, who was at that time the pathologist of Mercy Hospital. Acting on Dr. Black's suggestion, Dr. Cook has made bacteriological examinations of the mouth with reference to tuberculous infection in two hundred and twenty cases. While he does not say that all tuberculous infection of the lymphatic glands of the neck takes place through decaying teeth, he thinks it very significant that the pulp canals of such teeth often become tuberculous, since, by reason of the close anatomical connection of the lymphatics with the teeth and with the mucous membrane of the mouth, the canals may readily become the portals of infection.

Dr. Cook gives succinct accounts of eleven cases in which tubercle bacilli were found in or about decayed teeth. One of them was that of a girl, seventeen years old, who had been in rather poor health for some time, and whose teeth had been somewhat neglected. The first and second right molars of the lower jaw were badly decayed. Bacteriological examinations were made on several successive days. On the third day a tuberculous focus was found in the second molar. After several more examinations, at intervals of a few days, the teeth were extracted. Five weeks later the girl returned with a small nodule at the lower border of the inferior maxilla. Dr. Cook told her it was probably tuberculous and advised her to consult a physician at once. Her physician adopted local treatment and assured her that the trouble would soon pass away. However, other nodules began to form, and she

consulted another physician, who advised an operation for the removal of the glands. But this advice was not followed, and when last heard from, having left the country, the girl had pulmonary tuberculous disease.

Dr. Cook points out the desirability of more thorough inquiries into the conditions of the saliva that make it a good medium for the development of the micro-organisms that are found in the mouth, for, he says, it has been shown by a number of investigators that normal saliva is destructive to a great many forms of bacteria. We think it can not be doubted that the author has done an important piece of work in this investigation, one that distinctly emphasizes the importance of taking care of the teeth.

BLUE GLASS AS AN AID TO DIAGNOSIS IN SYPHILIS.

THE use of blue glass as a means of pursuing investigation into syphilitic and other eruptions, either before they have come into the limit of unaided vision or after they have passed beyond it, was suggested by Broca so early as 1893. Haan, in a paper in the *Journal des maladies cutanées et syphilitiques* for October, 1898, without, however, referring to Broca's researches, stated that for some years he had been in the habit of using a glass of cobalt blue in the diagnosis of cutaneous diseases.

Jullien, in the *Archives de dermatologie et de syphiligraphie* for January, 1899, pursues the question further. He himself uses an ordinary binocular fitted with lenses of cobalt-blue glass, of differing intensities of color, similar to the lenses found in cases fitted up for ophthalmoscopic examination. It is necessary to avoid too brilliant a light; a diffused light, similar to that from a cloudy sky, being the best. The glass must be placed as near as possible to the eye to escape diffusion of the rays and to protect the eye from all extraneous light. Under such conditions the appearances are resolved into variations in intensity in a monochromatic picture. Of course dirt and erythematous macule due to pressure or accidental irritation must be guarded against.

What is aimed at is the absorption of those rays of harmful light which fatigue the retina without bringing to its notice any essential distinguishing features. These, of course, in the present investigations, are principally the red rays. Now cobalt blue gives a spectrum of bands analogous to those of haemoglobin. It displays a broad band in the least refrangible portion of the red, one in the orange, one broad but weak in the green-yellow portion, and a feeble one in the green. Between

these bands it notably absorbs the rays, places an absolute impediment to the passage of the red rays, and excludes nearly everything but the green and blue rays.

Broca announced by this means the attainment of the following results: 1. The perception of an eruption before it becomes visible to the naked eye. 2. The displaying of traces of a former eruption. 3. The revelation of a latent eruption.

The anticipation of an eruption is a matter of some moment in forming an early diagnosis; while much may be gained as a confirmatory measure by the employment of this method when the eruption is already visible.

As for latent eruptions, with this method such things practically become non-existent. Cases, for instance, such as have been commonly reported of late, in which syphilis appears to have come spontaneously to a clean stop, after the chancre has disappeared, without the intervention of any treatment, only, perhaps, to reappear at the end of some years, present evidence by this method of examination of the presence of the poison in the system. As Broca pointed out, when a spot appears upon the skin, the point where it is situated has been already for some time the seat of some alteration; while, when an eruption disappears, the morbid process is not interrupted as soon as the eye fails to recognize it any longer.

For a considerable but variable period after the disappearance of an exanthem, as is the case with scars, the tegumentary vascular system does not regain its integrity of function; the tunics of the Malpighian arterioles retain from the neoplastic infiltration a more or less durable tendency to distention under the influence of irritating causes—variations of temperature, chills, hot baths, etc. Consequently, alterations must persist which are not visible to the naked eye, and it is these alterations that, according to the author, blue glass will enable us to detect for a long time in the form of a distinct blush. These stigmata persist longest about the axillæ, the scapular prominences, and the ribs, and even on the flanks and about the umbilicus.

Single examinations, however, are not to be trusted. When anticipating an expected eruption, examinations require to be made at frequent intervals; while, when trying to keep track of the disappearance of a morbid process, they should be repeated once a week. By these means, not only is great assistance rendered to the treatment of disease, when seen in its early stage, by showing when it should be pushed and when it may safely be suspended; but, when seen in the later stage, a valuable confirmatory reinforcement is added to the factors forming a suspected diagnosis.

SULPHONAL POISONING.

MUCH has been written concerning both the therapeutic and the toxic properties of sulphonal. Perhaps the latter have rarely if at all been considered more satisfactorily, from the point of view of the practitioner of medicine, than by Dr. G. Lovell Gulland, in the March number of the *Scottish Medical and Surgical Journal*. Dr. Gulland takes as his text a case that came under his own observation, that of a man, thirty-nine years old, given to the excessive use of alcohol, but free from any decided manifestations of impairment of health due to his indulgence. For a period of about six weeks, apparently, he took thirty grains of sulphonal every night, so that he had taken, in all, at least 1,200 grains. Then he became somnolent, with hæmatoporphyrinuria, passed into a state of coma, and died. At the post-mortem there was found, in microscopical sections of the liver, a degeneration of the branches of the portal vein such as the author has not found described before. He suggests that it may have gone so far at some point as to give rise to an opening through which liver cells may have passed into the blood.

Hæmatoporphyrinuria, says Dr. Gulland, is usually assumed to be the cause of death, and hence it is argued that sulphonal is a blood poison in the sense that potassium chlorate and aniline are blood poisons; but, he adds, it appears to have been overlooked that sulphonal may kill without producing hæmatoporphyrinuria, especially in the acute cases. It seems probable to him that the cause of death is uræmia (in the widest sense of the word), but that the symptoms of that condition are masked by the effects of the drug.

Dr. Gulland does not think that sulphonal should be regarded as a dangerous drug, but he pleads for greater caution in its use, and especially for greater discrimination in the choice of cases in which it is to be used. "Its apparent capriciousness of action," he says, "is its chief danger, and a drug which has a recorded death-roll of at least thirty cases, and probably many more unrecorded, is not one which should be recommended with a light heart to the first-comer." Its advantages in causing a restful sleep and in being less disagreeable to the taste and less expensive than trional are mentioned as perhaps at the bottom of the fact that it is not being to a great degree superseded by trional in Great Britain, as is the case in Germany.

Sulphonal should not be given, says Dr. Gulland, if there is great prostration, if there is gastro-intestinal disturbance, especially constipation (for it is prone to be retained in the intestine and undergo slow absorption, with the result of proving cumulative in its action),

in cases of heart disease, in old people, or if there is a parenchymatous kidney lesion, acute or chronic. The maximum daily amount to be given to a man should be thirty grains, and to a woman from fifteen to twenty grains. It should never be given continuously, but pauses of at least three or four days should be allowed from time to time, to allow of elimination of the accumulated drug.

Dr. Gulland thus sums up the treatment of sulphonal poisoning: In the acute form, as the drug is absorbed but slowly, the stomach should be emptied if the patient is seen early enough, and spontaneous vomiting, if present, should be encouraged. Then purgatives may be given, to rid the intestine of the drug so far as possible. Every available means should be employed to keep the kidneys acting freely. Large enemata of warm water were found by Neisser to produce free diuresis in the case of a patient whose life he saved after 1,500 grains had been taken in a single dose, and probably it would be well to try them. For the rest, the treatment must be symptomatic. In chronic poisoning it is well to clear out the bowels and promote diuresis, but the best results have followed the free use of alkalis. Both the bicarbonates and the acetates or citrates should be given, to control the hæmatoporphyrinuria. Unless the poisoning is very slight, the prognosis is very unfavorable, no matter what remedies are used.

ACUTE POISONING BY HYDRASTIS CANADENSIS.

MIDONSKI (*Berliner klinische Wochenschrift*, No. 5, 1889; *Gazzetta degli ospedali e delle cliniche*, February 16th) relates the case of a man with chronic bronchitis accompanied by profuse bronchorrhœa, but without other lesions, for whom he prescribed twenty drops of fluid extract of *Hydrastis canadensis* three times daily to constrict the engorged pulmonary vessels and to diminish inflammation and secretion. The next night he was summoned in haste and found the patient livid, with his lips and tongue cyanotic, respirations frequent and accompanied by forced contraction of the auxiliary respiratory muscles. There were inspiratory râles, audible at a distance, and stridulous expiration. The pulse was small, compressible, and slow. There were cold sweats. On auscultation of the lungs grave symptoms of diffuse pulmonary œdema were found, the bronchial respiration being only faintly audible. The heart sounds were inaudible and the cardiac impact was not to be felt. Stimulants, as ether, wine, coffee, and sinapisms, restored the patient, who said that shortly after taking the last two doses he felt some difficulty of breathing, which continued to increase until it arrived at the point described. The author attributes these symptoms to a noxious action of the drug on the fibres of the myocardium causing acute dilatation. This view, he says, accords with Fellner's results obtained upon animals. The Italian translator suggests that another explanation is possible—namely, that the acute dilatation was caused, not by the drug's action on the cardiac

fibres, but by a sudden elevation of arterial pressure, the vaso-constrictor effect applying not only to the pulmonary vessels, but to the entire vascular system. Whatever be the explanation, it appears evident that the drug has a cumulative effect which, in the employment of large doses, no matter in what affection, must be carefully guarded against.

THE ACADEMY OF MEDICINE'S CONSIDERATION OF SYPHILIS.

SYPHILIS is a subject in which every practitioner of medicine is interested, whether his practice is general or special, in city or country. The disease is protean in its manifestations, and one or more of them may complicate any pathological situation; therefore it has to be borne in mind in all but the simplest cases of disease. Such a subject needs to be turned over, so to speak, from time to time in a thorough and systematic way, so that one's forgotten knowledge may be brought back and reinforced with fresh acquisitions. This kind of work, in our opinion, can not be done satisfactorily in an off-hand discussion of a paper read before a society. Hence we think it a particularly happy conception on the part of the president of the Academy of Medicine to have substituted for such a discussion the reading of a number of papers by observers peculiarly well qualified to present the subject from various points of view, and then to have arranged for their publication in a collected form. In this week's issue, in accordance with such arrangement, we present the papers by Dr. Bangs, Dr. Dawbarn, Dr. Fox, and Dr. Taylor, being those that were presented on the first evening devoted to the subject. It is unnecessary for us to speak of their merits, for their authors are widely known as masters of the matters of which they had to treat. As we have intimated, more than one evening was devoted to the consideration of syphilis, and we expect to bring out soon the papers that were presented in the further pursuance of the subject. We are glad to learn that it is Professor Thomson's purpose to treat other themes in the same manner, and that one of them is that of malaria and its effects.

THE SERRATED POISON-BOTTLE BILL.

It is an excellent provision to require dangerous poisons to be put up in receptacles having some peculiarity calculated to make the heedless take warning, but we must regard as pernicious that requirement of Senator Wilcox's bill, which, we understand, has been passed by the legislature of the State of New York, making it obligatory to put every medicine containing even the slightest amount of any poison (except patent and proprietary medicines) into an octagonal bottle with serrated edges and bearing indented or in-relief the traditional skull and cross-bones. There is hardly any medicine that is not poisonous, but to so proclaim a weak opiate mixture would be to rouse the apprehension of a timid patient, and perhaps aggravate his ailment, quite without reason. Moreover, if medicines put up on prescription are to be so treated, we fail to see why patent and proprietary preparations should be exempted. It has been suggested, moreover, that, if the use of such bottles is made compulsory, in a short time they will become very plentiful; they will not be destroyed after their special use, but will be employed to hold any harmless substance for which a bottle is re-

quired. It is easy to see that in the end, therefore, they will prove far more dangerous than ordinary bottles or phials. Their very oddity will be an incentive for preserving them.

DR. SCHENK AND PUBLICATION IN LAY JOURNALS.

We learn from the *Revue médicale* for March 22d, citing French newspapers, that the Academy of Science of Vienna has decided to discipline Dr. Schenk for having announced his alleged discovery regarding the production of sex at will through the medium of the lay press in place of making it public through the medical reviews—a course which the academy deems derogatory to his dignity as a savant. We cordially indorse the academy's opinion on this point.

A CURIOUS CASE OF APPENDICULAR COLIC.

PROTEAN indeed are the manifestations of trouble with the vermiform appendix. An interesting example is recorded by Dr. Goldbach, of Prague (*Prager medicinische Wochenschrift*, 1898, No. 16; *Centralblatt für innere Medizin*, March 18, 1899), that of a lad, sixteen years old, who for a year had suffered from frequent attacks of jaundice ushered in by vomiting and accompanied by colicky pains under the right ribs. The pains occurred particularly in the evening, and the attacks usually lasted about a week. There was no fever, but there was frequently constipation lasting for several days. After a time the pain became more restricted to the ileo-cæcal region and radiated backward. There was typical tenderness on pressure in the ileo-cæcal region, and there was a soft oval tumor on the surface of which the vermiform appendix could be felt. It shifted its position very freely, being found sometimes in the hepatic region and at other times in the lower part of the abdomen. At the patient's earnest solicitation, Dr. Wölfler performed laparotomy. The cæcum and the vermiform appendix itself were found perfectly normal. The appendix was rather more than three inches long. Two little concretions could be felt in the cæcum, and they could easily be shoved into the appendix. No narrowing of Gerlach's valve could be made out. This structure was removed, together with the concretions. The patient made a good recovery, and nine months later he was found to be in perfect health and free from pain, although he was accustomed to great bodily exertion. Dr. Goldbach thinks that the reason the pain was more pronounced in the afternoon in this case was that during the digestion of the dinner the concretions were forced into the vermiform appendix. This process took place every day.

PASSENGER SHIPS AS A MEANS OF CONVEYING TUBERCULOSIS.

DR. HENRY STRACHAN, chief medical officer, Lagos (*Journal of Tropical Medicine*, March), draws attention to the risk run by passengers to the West African colonies of contracting tubercle on the voyage, on board the ships conveying them. So many poor sufferers from phthisis, he says, form the majority of the passengers to Madeira and the Canaries at certain times of the year that the probabilities are great that most cabins will more or less be infected with tubercle, and it is by no means unlikely that a passenger will find himself or herself cabin mate with some *poitrinaire* whose expectoration is profuse and frequent, and whose cough is, at

night, most distressing. This is not as it should be in these days when all are agitating for the establishment of means for preventing the spread of what is acknowledged to be a communicable disease. Dr. Strachan suggests that cabins should be reserved for the use of invalids suffering from "chest complaints," or, if this is not possible, all cabins should be disinfected at the end of each voyage, and the bedding of the berths, or at least the pillows, renewed. In the meantime, he advises every traveler to take his own pillows with him. These remarks apply in a lesser degree to all passenger ships, and are worthy of careful consideration.

A CAUTION AS TO THE USE OF BALSAM OF PERU.

ALMOST any topical application may be productive of untoward effects in certain instances. An illustration of this fact was recently presented by M. Hallopeau and M. Léri at a meeting of one of the French societies (*Presse médicale*, March 11th), the case of a child with scabies in whom an application of balsam of Peru had provoked a pustular eruption. The statement was made that even death had been caused by the use of the balsam, and the caution was given not to apply it over a large surface or one that was the seat of excoriations.

THE REMOTE EFFECTS OF COMPRESSION OF THE FETAL HEAD.

In the March number of the new journal *Obstetrics* there is an editorial article in which the writer states that he has been unable to find in literature anything satisfactory bearing upon the effects upon the brain in adult life of forceps traction and head-molding in the birth of the individual. He intimates that such effects are probable, and suggests the subject as one deserving of elucidation. The suggestion seems to us worthy of careful consideration.

BOTANY AS A DIVERSION.

ACCOMPANYING a circular recently issued announcing summer courses in botany, to be given jointly by the Torrey Botanical Club and the College of Pharmacy of the City of New York, there is a slip stating that many patients have found in such courses a wholesome and grateful recreation for mind and body, and therefore calling physicians' attention to the circular. This is a good suggestion, it seems to us. There are many states of invalidism in which botanizing expeditions are well calculated to aid materially in bringing about recovery.

THE OVARIAN ORIGIN OF CHLOROSIS.

THE experience of several speakers at a recent meeting of the Nancy Society of Medicine (*Gazette hebdomadaire de médecine et de chirurgie*, March 26th) seems to support the theory of the ovarian origin of chlorosis. Several cases were mentioned in which the administration of ovarian extract had brought about a prompt restoration to health.

THE RECLAMATION OF RANCID BUTTER.

Lyon médical for March 5th states that rancid butter may be deprived of its disagreeable taste by working it

with water containing from three hundred to four hundred and fifty grains of chlorinated lime in rather more than two pints and a half, or containing a small quantity of sodium bicarbonate. When the unpleasant taste has disappeared, it is to be worked again with water, and it will then be found to have been reclaimed. Its appearance is improved, also its taste, by working it with milk. This is a matter well worthy of attention in connection with the provisioning of charitable institutions, ships, and the like.

A TYPHOID-FEVER ANTITOXINE.

DR. JEZ recently reported to the Vienna College of Physicians (*Presse médicale*, March 4th) certain observations which he took to indicate the curative effect of an extract made from various organs of rabbits killed after having been treated with intraperitoneal injections of virulent cultures of typhoid-fever bacilli. It is to be feared, however, that the evidence is not convincing enough to warrant us in building any great expectations on it, for it amounts only to the observation that the duration of the disease was abridged.

ESSENTIAL TREMOR IN AN HYSTERICAL MAN.

AT a recent meeting of the Paris Medical Society of the Hospitals (*Presse médicale*, March 4th) M. Antony presented a young soldier who had been affected with tremor of the right upper extremity since the age of seven years. On reading this part of the account, one naturally wonders that such a person should have been received into the French army, but as we proceed we find that, although there were certain hysterical stigmata, they were probably superadded, and the man's trouble was the essential tremor of degeneracy, one that, as M. Raymond remarked, could be moderated by an exercise of the will. The soldier's father was affected with alcoholism.

INTRAVENOUS SALINE INJECTIONS IN PUERPERAL MANIA.

AT a recent meeting of the Paris Obstetrical Society M. Boullé (*Presse médicale*, March 4th) related the case of a woman who made attempts at suicide during her pregnancy. Her labor was normal, but was followed at once by hallucinations, shrieking, a subicteric hue of the skin, a temperature of 101° F., and a pulse of 143, so that at first infection was supposed to have occurred. This diagnosis was discarded—why, is not stated; perhaps it was on account of the suicidal attempts before labor—and that of acute mania substituted. The treatment was the enforcement of an absolute milk diet and the use of intravenous saline injections. There was progressive amelioration, and soon the object of the first few days was succeeded by polymeria. Recovery was complete in sixteen days from the time of delivery.

THE ETIOLOGY OF ALOPECIA PRÆMATURA.

DR. J. M. BLAINE, in the *Transactions of the American Medical Association* for March 11th, expresses some novel views as to the etiology of premature alopecia baldness. Leaving out of consideration cases connected with syphilis and parasitic disease, he passes rapidly in review the reasons advanced by various authors for the fact that premature baldness is commoner in men than

in women, giving what appear to be good grounds for rejection *seriatim*, and then proceeds to adduce two sets of examples to show that this premature loss of hair from the scalp is due to the habit of shaving. The beardless races, Indians, etc., are noted for their luxuriant growth of hair on the scalp. Bearded savage races also are not deficient therein, because, in his opinion, they do not shave their beards. Shaving stimulates the growth of the beard to its utmost limit, causing hyperæmia of the face, and thereby lessening the supply of nutriment to the hair bulbs of the scalp. The beards of those who have become prematurely bald on the scalp, when subsequently allowed to grow, are rarely if ever affected. The facial artery, Dr. Blaine points out, branches off from the external carotid opposite the angle of the lower jaw, while the main artery finally bifurcates into the anterior and posterior temporal, which supply the entire scalp as far back as the occiput, or, in other words, the part which usually becomes bald. The nerve supply of the occipito-frontalis muscle is obtained from the facial nerve, hence nothing in the human economy could be brought into more intimate sympathy than the blood and nerve supply of the face and scalp. He suggests that in order to maintain the equipoise between the hair and the beard, every man should allow his hair to grow between the ages of twenty-five and thirty-five years. At first glance there is at any rate a good deal to be said in favor of Dr. Blaine's contention.

THE DELUSIVE CLIMACTERIC.

FULL many a woman, no doubt, has relied on her years as a safeguard against conception, and been sadly undeceived. It is somewhat startling, nevertheless, to learn from the *Journal de médecine de Paris* for March 12th that last year [1899 is printed, but we presume 1898 is meant] seventy-seven illegitimate children were born in France of mothers over fifty years old. The French people have been exercised for some time now over the decline of their birth rate. Let them take heart if this is what their old women can do.

CHILDBIRTH AMONG THE INDIANS.

It is customary to hear the arguments in favor of a more hygienic costume and more rational habits for women enforced by an appeal to the experience of uncivilized nations, which are singularly free from derangements of the female generative organs and from difficulties of parturition; and these matters are, therefore, with considerable reason, held to be largely induced by modern feminine dress and manners. But a still more startling evidence of the truth of that view is forthcoming in a paper by Dr. C. Bailey Bell, writing from Vinita, I. T. (*Medical and Surgical Bulletin*, February; *North American Medical Review*, March), who points out that in his experience, and in that of Dr. Fortner and Dr. Bagby, "who have done the largest practice in the Territory for years," the women of the five civilized Indian tribes who have learned to follow closely their white sisters in dress and habits of life suffer more frequent complications of parturition than are common among uncivilized Indian, or even white, women. This latter disparity the author considers due to the fact that the change of dress, habits, customs, etc., has been less the result of gradual evolution than of a sudden revolution. Even when the change is in the right direc-

tion, a radical and sudden change is rarely a good thing. Nature works its greatest wonders by slow and silent processes, and human nature would do well to imitate non-human nature in that respect. In the present instance, the more natural modes have exploded suddenly into the restraints of convention, and the result has not been fortunate. There are many points in which the present feverish haste of life might well retrace its steps gradually in the direction of simpler tastes, simpler aims, simpler needs, and simpler customs.

THE FUTILITY OF GARGLING.

THE laryngologists have often told us of the uselessness of gargles; and now Dr. Säger is cited by the *Lancet's* Berlin correspondent as having pointed out in the *Münchener medicinische Wochenschrift* that there can be no therapeutic effect from a gargle unless it comes in contact with the affected part, and as having demonstrated that it does not reach the pharyngeal mucous membrane and the tonsils. This he has done by brushing the tonsils with methylene blue and then making the person gargle with water, which was afterward ejected perfectly colorless. He also, in another set of experiments, dusted the throat with flour and then had the person use a gargle containing iodine. The blue color resulting from the reaction appeared only on the velum palati and the tongue.

THE LATE PROFESSOR CANTIERI.

THE Rome correspondent of the *Lancet* for March 25th describes with gentle and sympathetic pen the tragic end of Professor Cantieri, "The Nestor of the Sienese medical faculty," who, at the advanced age of seventy-eight, terminated his life by shooting himself with a rifle in his study. Letters left behind him showed that his weariness of life arose from the incessant strain upon him occasioned by his constantly having to pay debts contracted by his relatives, while at the same time his advanced age precluded the possibility of his earning an income adequate to this drain. He adds pathetically, *Non sono pazzo. Conosco e so pienamente quello che sto per fare* (I am not mad. I am fully conscious and aware of what I am about to do). As might be expected, the funeral of one who has all through his life been held in the highest esteem and regard by all with whom he came into contact was impressive and dignified to a great degree. It is lamentable when those who have labored diligently and faithfully are, through no fault of their own, driven upon the rocks in their later years, but it teaches a lesson much needed in these commercial days, that worldly success is by no means an evidence of worth, or *vice versa*.

ERUCTIONS OF INFLAMMABLE GAS.

IN its issue for March 12th the *Journal de médecine de Paris* recounts that Dr. Drouet, of Meulan, reports the case of a child, two years and a half old, whose throat he was examining with the aid of a tongue-depressor and the traditional candle, when a blue flame issued from the child's mouth, like that of a spirit lamp. It soon went out, but not until it had burned the doctor's mustache and the child's lips. We quite agree with our contemporary in the exclamation, *Il y avait de quoi!*

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 1, 1899:

DISEASES.	Week ending Mar. 25.		Week ending Apr. 1.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	8	3	8	6
Scarlet fever.....	155	21	173	16
Cerebro-spinal meningitis.....	0	13	0	11
Measles.....	283	11	259	12
Diphtheria.....	177	25	175	36
Croup.....	4	4	22	8
Tuberculosis.....	178	178	251	166
Small-pox.....	0	0	1	0
Chicken-pox.....	24	0	27	0

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general of the United States Marine-Hospital Service during the week ending April 1, 1899:

Small-pox—United States.

Los Angeles, Cal.....	Mar. 11-18.....	2 cases, 1 death.
Denver, Col.....	Mar. 4-11.....	1 case, 1 "
Denver, Col.....	Mar. 11-18.....	3 cases, 1 "
Washington, D. C.....	Mar. 25-29.....	5 "
Jacksonville, Fla.....	Mar. 23.....	12 " to date.
New Orleans, La.....	Mar. 11-18.....	5 "
Baltimore, Md.....	Mar. 25.....	1 case.
Kalamazoo, Mich.....	Mar. 11-18.....	2 cases, 1 death.
Buffalo, N. Y.....	Mar. 15-21.....	1 case.
Elmira, N. Y.....	Mar. 18-25.....	1 "
Cincinnati, Ohio.....	Mar. 11-18.....	2 cases.
Pottstown, Pa.....	Feb. 4-11.....	1 case.
Norfolk, Va.....	Mar. 30.....	1 "

Seman on S. S. Newport News.

Petersburg, Va.....	Mar. 4-11.....	1 case.
Portsmouth, Va.....	Mar. 22-25.....	51 cases.
Spokane, Wash.....	Mar. 11-18.....	2 cases.

Small-pox—Foreign.

Buenos Ayres, Argentina.....	Dec. 1-30, 1898.....	5 deaths.
Bahia, Brazil.....	Feb. 26-Mar. 1.....	3 cases.
Rio de Janeiro, Brazil.....	Feb. 10-17.....	5 " 1 death.
Cairo, Egypt.....	Feb. 18-Mar. 1.....	2 deaths.
London, England.....	Feb. 25-Mar. 11.....	1 " 1 "
Bombay, India.....	Feb. 11-21.....	1 "
Calcutta, India.....	Feb. 1-11.....	1 death.
Madras, India.....	Feb. 11-17.....	1 "
Nagasaki, Japan.....	Feb. 11-21.....	1 case.
Mexico, Mexico.....	Mar. 5-12.....	7 cases, 4 deaths.
Mexico, Mexico.....	Mar. 12-17.....	7 " 1 death.
Moscow, Russia.....	Feb. 19-26.....	10 " 1 "
Odessa, Russia.....	Mar. 1-11.....	1 case.
Warsaw, Russia.....	Feb. 25-Mar. 11.....	6 deaths.
St. Petersburg, Russia.....	Feb. 25-Mar. 11.....	5 cases.

Yellow Fever.

Rio de Janeiro, Brazil.....	Feb. 10-17.....	57 cases, 57 deaths.
Barraququilla, Colombia.....	Feb. 18-25.....	2 " 2 "
Barraququilla, Colombia.....	Feb. 25-Mar. 1.....	1 case, 1 death.
Vera Cruz, Mexico.....	Mar. 16-23.....	2 deaths.

Cholera.

Bombay, India.....	Feb. 25-Mar. 4.....	1 death.
Calcutta, India.....	Feb. 4-11.....	17 "
Calcutta, India.....	Feb. 11-18.....	26 "
Madras, India.....	Feb. 18-21.....	1 death.

Plague.

Bombay, India.....	Feb. 25-Mar. 4.....	17 deaths officially reported.
Calcutta, India.....	Feb. 4-11.....	Probably 1,000.
Calcutta, India.....	Feb. 11-18.....	1 death.

A Memorial of the Late Dr. Joseph O'Dwyer.—A committee of over forty physicians, representing sixteen different medical societies of the city of New York and including representatives of both schools of medicine, has been formed for the purpose of doing honor to the memory of Dr. Joseph O'Dwyer.

The first meeting was held at the New York Academy of Medicine, on November 22, 1898, under the chairmanship of Dr. Joseph D. Bryant, and was mainly devoted to organization. Dr. George F. Shrady was elected permanent chairman, and Dr. Alfred Meyer permanent secretary, and the following committee on scope and plan was appointed: Dr. Dillon Brown (chairman), Dr. Robert Abbe, Dr. R. G. Freeman, Dr. L. Emmett Holt, and Dr. Louis Fischer. At the second meeting, held at the Academy of Medicine on March 13, 1899, the report of the committee on scope and plan was adopted and now only awaits final action of a meeting of the full committee.

The memorial to Dr. O'Dwyer will probably take an educational form, for by the plan now outlined it is proposed to raise a fund of thirty thousand dollars, the interest of which shall support two O'Dwyer fellowships in paediatrics, open to competition by physicians who graduate in the United States and to be held by the successful competitors for a period of two years. During this period they must furnish satisfactory proof of their engagement in original research work to a committee of five, one of whom shall be appointed by the president of Harvard University, one by the dean of the Johns Hopkins Medical School, one by the provost of the University of Pennsylvania, one by the president of the University of Chicago, and one by the president of the New York Academy of Medicine.

Many details of this general plan are still to be arranged, which the secretary will furnish to the medical press of the country so soon as they are finally decided upon. This preliminary notice has for its object merely to acquaint the profession with the fact that a movement of this nature is on foot, and that an effort will be made to give it the international character so fitting as a memorial to an investigator of international reputation.

"Zoolak."—This is an additional trade name recently adopted by Dr. M. G. Dadirrian, of New York, to distinguish the excellent nutritive preparation known as matzoon which he has furnished to the profession for the last fifteen years or more. In order to be sure that their patients will get a matzoon that is recognized as the standard, physicians should henceforth prescribe "zoolak."

The Medical Society of City Hospital Alumni, of St. Louis.—At the last regular meeting, on Thursday evening, the 6th inst., Dr. Charles Fahnestock reported a Case of Pulmonary Tuberculosis with Tuberculous Ulcers of the Oesophagus; Dr. Robert Terry exhibited gross sections of the human body, and Dr. Greenfield Sluder exhibited specimens of the nose and demonstrated methods of preservation.

A Foreign Military Medical Officer's Views on the Spanish-American War.—Major General Paulow, surgeon-general of the Norwegian Army and Navy (*St Paul Medical Journal*, April), who attended the American operations in Cuba, thus sums up the results of his interesting observations: "To give a brief resume of what I learned on my visit I must first mention that it was of

great interest to become acquainted with the organization of American sanitation, and to see how the Americans with their practical sense understood how to quickly organize new detachments and supply them with *personnel* and equipment. But I saw also how impossible it was, even with America's immense resources, to prepare even a small force in the beginning of the war, and I learn further, how little one can depend upon untrained masses, and how necessary it is for every nation who thinks of defending itself against regular armies to have everything down to the minutest detail in good shape, and to afford every one from the private to the highest officers in all their relations the greatest possible practice."

The St. Louis Medical Society.—At the last meeting, on Saturday evening, the 1st inst., the following papers were presented for discussion: A Capsulo-tenectomy; the most Accurate and Dependable Operation for Certain Cases of Squint of Insufficiency of External Eye Muscles, by Dr. F. W. Hilscher; Fat Metabolism, by Dr. T. C. Witherspoon; and The Surgical Treatment of Certain Forms of Sexual Impotence, by Dr. G. Wiley Broome.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Surgery, on Tuesday evening, the 4th inst., Dr. Roswell Park read a paper on Acute Osteomyelitis, which was discussed by Dr. Herman Mynter, Dr. Hartwig, and others. Dr. Chauncey P. Smith reported a case.

The Japanese and Sanitation.—The *Texas Medical Journal* for March says that the Japanese believe in sanitation. The town of Teukchem, on the island of Formosa (taken from the Chinese), has a population of forty thousand, with a high death-rate. It is situated in a swamp, and can not be drained. The government has caused the inhabitants to pull up, root and branch, and move to a higher site, some miles off, giving to each householder the same size lot as he had at home, and—as the new town was laid off somewhat after the pattern of the old one, except that the streets are wider—a location corresponding to the one he vacated. The government put in sewers, water, light, etc., at public cost.

The writer adds: I wish we had a Japanese governor and legislature in Texas.

A New Hospital for Brooklyn.—We understand that a scheme is on foot to supply a new hospital for Brooklyn, to be called the Breadwinner Hospital, which, while it will depend largely upon voluntary contributions, will derive part of its maintenance income from the payments exacted, according to their means, from the patients themselves. It will therefore enable the really worthy poor to accept hospital relief without pauperizing themselves. Dr. Skene is interested in the new institution, being on the medical board.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 25 to April 1, 1899:*

BANISTER, WILLIAM B., Captain and Assistant Surgeon, is detailed as a member of the examining board appointed to meet at Augusta, Georgia.

BOWEN, WILLIAM C., Captain and Assistant Surgeon, is detailed as a member of the examining board appointed to meet at Washington.

BRATTON, THOMAS S., First Lieutenant and Assistant Surgeon, will report to the examining board appointed to meet at Washington for reexamination for promotion.

DEAN, ELMER A., First Lieutenant and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at St. Paul for the examination of officers for promotion.

DOTCHER, BASIL H., First Lieutenant and Assistant Surgeon, is granted leave of absence for two months, to take effect upon the completion of his duties as a member of the examining boards at Fort Leavenworth, Kansas, if his services can be spared.

EDIE, GUY L., Major and Brigade Surgeon, is relieved from further duty at the Presidio of San Francisco, and is assigned to duty with troops sailing on the first transport from San Francisco to Manila.

GIRARD, ALFRED C., Lieutenant-Colonel and Chief Surgeon, is relieved from further duty with Second Army Corps, and will proceed to Vancouver Barracks, Washington, and report to the commanding general, Department of the Columbia, for duty as chief surgeon of that department.

GLENNAN, J. D., Major and Brigade Surgeon, is detailed as a member of the board of officers appointed for the examination of enlisted men serving within the department who may desire to take the examination for appointment as second lieutenant in the regular army.

GREENLEAF, CHARLES R., Colonel and Assistant Surgeon-General, will proceed to Fort Monroe, Newport News, Savannah, Atlanta, and Greenville to inspect the medical department at those stations.

HALLOCK, HARRY M., Captain and Assistant Surgeon, is relieved from further duty at the Josiah Simpson General Hospital, Fort Monroe, Virginia, and will proceed to Fort McPherson, Georgia, and report to the commanding officer at that post for duty.

HOWARD, DEANE C., Captain and Assistant Surgeon, is detailed for temporary duty as attending surgeon, New York, and will report to the commanding general, Department of the East.

IRELAND, M. W., Captain and Assistant Surgeon, will proceed to Chicago to assist in examining members of the Eighth Illinois Volunteer Infantry.

MANLY, CLARENCE J., First Lieutenant and Assistant Surgeon, is relieved from further duty with Batteries G and I, Second Artillery, Department of Havana, and will report to W. H. ARTHUR, Major and Surgeon, commanding the hospital ship *Missouri* at Havana, for duty.

PILCHER, JAMES E., Captain and Assistant Surgeon, is granted leave of absence for four months on account of sickness.

RAYMOND, HENRY L., Captain and Assistant Surgeon, will proceed to Fort Porter, N. Y., to accompany the Thirtieth Infantry to Manila.

SNYDER, HENRY D., Captain and Assistant Surgeon, will proceed at once to Savannah, Georgia, to take charge of the medical supply depot in that city, and relieve JAMES E. PILCHER, Captain and Assistant Surgeon.

SWIFT, E. L., Captain and Assistant Surgeon, is relieved from temporary duty in New York and will return to Fort Slocum, N. Y.

VAUGHAN, VICTOR C., Major and Division Surgeon, United States Volunteers, and SHAKESPEARE, EDWARD O., Major and Brigade Surgeon, United States

Volunteers, are assigned to duty in Washington, for an additional period of two months, for the purpose of completing their report.

WILSON, WILLIAM II., Captain and Assistant Surgeon, will proceed to the Josiah Simpson General Hospital, Fort Monroe, Virginia, for duty.

The Society of Medical Jurisprudence.—At the next meeting, on Monday evening, April 10th, Mr. Gino C. Speranza, of the New York Bar, will read a paper entitled *Natural Law vs. Statutory Law*.

Changes of Address.—Dr. Sidney V. Haas, to "The Blenheim," 2493 Broadway, New York; Dr. Theron W. Kilmer, to 170 West Eighty-fifth Street, New York.

Society Meetings for the Coming Week:

MONDAY, April 10th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, April 11th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Societies of the Counties of Jefferson (quarterly), Oneida (annual—Utica), Ontario (quarterly), Rensselaer, and Tioga (quarterly); Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Bergen (annual—Hackensack) and Cumberland (annual), N. J., County Medical Societies; Fairfield, Connecticut, Medical Association; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, April 12th: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Tri-States Medical Association (Port Jervis), N. Y.; Pittsfield, Massachusetts, Medical Association (private); Philadelphia County Medical Society; Kansas City, Missouri, Ophthalmological and Otolological Society.

THURSDAY, April 13th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; New York Laryngological Society; South Boston, Massachusetts, Medical Club (private); New London, Connecticut, County Medical Society (annual); Pathological Society of Philadelphia.

FRIDAY, April 14th: New York Academy of Medicine (Section in Neurology); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

Births, Marriages, and Deaths.

Married.

McLAURY—NEFF.—In Philadelphia, on Wednesday, March 29th, Dr. Daniel Henry McLaury, of New York, and Miss Sarah Josephine Neff.

PERINE—BENNET.—In Brooklyn, on Monday, April 3d, Mr. William De Nyse Nichols Perine and Miss Mae Bennet, daughter of Dr. George H. R. Bennet.

Died.

ASHWIN.—On Tuesday, March 28th, Dr. Edward Hilborne Ashwin, of Brooklyn, in the fifty-fifth year of his age.

CHASE.—In New York, on Saturday, March 25th, George Abbot Chase, only child of Dr. George T. Chase.

ENTLER.—In Oneonta, N. Y., on Monday, April 3d, Dr. George F. Entler, aged forty-nine years.

FIELDS.—In New York, on Thursday, March 30th, Mrs. Emma Fields, wife of Dr. William J. Fields.

PENDLETON.—In Pine Bluff, Arkansas, on Sunday, March 26th, Dr. Pleasant H. Pendleton, aged forty-five years.

SEAMAN.—In New York, on Wednesday, March 29th, Valentine Seaman, father of Dr. Louis L. Seaman, in the ninety-seventh year of his age.

SHAAKE.—In Lawrence, Massachusetts, on Monday, March 27th, Dr. Frederick H. Shaake, in the thirty-fifth year of his age.

VISSMAN.—In Morristown, N. J., on Wednesday, March 29th, Dr. William Vissman, in the thirty-fourth year of his age.

Special Articles. •

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

XIII.

RIGHTS AND LIABILITIES OF THIRD PARTIES.

(Continued from page 496.)

Ratification.—While the railroad company is ordinarily under no obligation to pay for the services of a physician employed by an employee or inferior officer, it frequently happens that the company becomes liable for the payment of a physician's fee when he is primarily so employed, through the ratification of such employment by the conduct of the higher officers of the company.

It is a well-established rule of law that such a hiring can not be ratified excepting by an officer whose power and authority are sufficient to enable him to make the contract primarily which he assumes to ratify by subsequent words or conduct.*

The question of whether or not the facts in a given case amount to a ratification of an unauthorized hiring is usually one for the jury to determine. The doctrine can therefore be better illustrated by examining a few cases than in any other way.

* T. W. and W. R. R. Co. v. Rodriguez, 17 Ill., 189.

In the case of *Pacific Railroad Company vs. Thomas*, a physician was employed by the assistant master mechanic and the section boss to attend an employee who was injured. This hiring did not have the effect of obligating the company to pay the physician for his services, notwithstanding both the section boss and assistant master mechanic said that they would see that the railroad company paid him; but the physician, before he had finally completed the services, sent a letter to the superintendent of the railroad, explaining the circumstances of his employment and inclosing a bill for his services. The superintendent paid no attention to this letter and bill. The jury found upon this evidence that the superintendent had by his acquiescence ratified the original contract of hiring.*

The station agent requested one Rodrigues to nurse and take care of a brakeman who had been injured, and told him that the railroad company would pay him for the services. Soon after he wrote to the general superintendent, informing him what had been done, but received no reply. Rodrigues, after performing the services, presented his bill to the station agent for payment. Soon afterward the superintendent conferred with the station agent in reference to the various items, and as to whether the charges were reasonable. The superintendent made no objection at the time, but said if the charges were reasonable he would pay the account. This was held a ratification.†

In the case of the *Terre Haute and Indiana Railroad Company vs. Stockwell*, the conductor of a train which ran into and injured a man employed a physician to dress the wound and take care of the injured man. He then sent a telegram reporting the affair to the general superintendent and general agent, and that evening, upon arriving in St. Louis, he reported to the general superintendent in person that he had struck a man and had employed a physician to dress his wounds. The physician, after rendering the services, addressed a letter to the president of the company, stating the circumstances of the employment, the services he had rendered in a general way, and demanding pay therefor. The railroad company never questioned or repudiated the employment as made by the conductor, not even after receiving the physician's letter. From this evidence the court found that the employment of the physician by the conductor was ratified and confirmed.‡

Where the station agent employed a physician to treat an injured employee with the understanding that the company would pay, and the general superintendent on the following day came to the town where the injured employee was and inquired of the station agent regarding him, and seemed to be informed regarding the character of the injury and the treatment of the surgeon, but made no objection or complaint in reference to the action of the station agent in employing a surgeon, of which he was apprised, and a few weeks later the general superintendent in conversation with the physician informed him that the pay would be all right, the contract of the station agent was considered ratified.§

In the case of *Toledo, Wabash, and Western Railroad Company vs. Prince*, a surgeon was employed by

the station agent to take charge of a wounded man. The station agent reported the case to the general superintendent a few days afterward, and heard nothing further until he presented the bill. The superintendent then refused payment. The jury found a verdict for the plaintiff on the ground of ratification. The supreme court of Illinois sustained the judgment of the trial court, and in commenting on the case said: "If the superintendent desired to save the company from being held responsible, he should, on receiving the report of the case, have dissented from the action of the station agent, and directed him to apprise the surgeon of such dissent, instead of allowing the latter to continue his services under the belief that he was in the employ of the company."*

In apparent conflict with this and some of the preceding cases is a recent case decided by the supreme court of California, upon a statement of facts very similar to the case above given. The trial judge instructed the jury that if the defendant knew that the plaintiff was treating the injured man on its account, and relied for compensation on the defendant, and the defendant made no objection thereto, then the defendant was liable. Upon this instruction the jury rendered a verdict for the plaintiff, but the supreme court reversed the judgment, stating its reason as follows: "We conclude that knowledge upon the part of defendant that the plaintiff was rendering services to the injured man, and also knowledge of defendant that plaintiff was relying on it for compensation for the performance of such services, taken in connection with the fact that defendant, possessing such knowledge, made no objections thereto, are circumstances wholly inadequate to create a legal liability against defendant."†

While those physicians living in the States in which the cases above cited were determined know how the courts of their respective State will hold, those living in States where the particular question has not been adjudicated can not predict with certainty which precedent their courts will follow; it therefore behooves them to be well within the requirements of the rule recognized by the California courts. To do this, a physician should immediately upon being employed by an inferior officer or agent of a company to render services for such company, write to some officer who has power to make such a contract, informing him of the hiring, stating that he has undertaken the treatment of the patient on behalf of the company and expects them to pay his fee; and if the agent originally hiring him is without authority so to do, he desires to be informed at once and to be instructed whether or not to proceed with the treatment of the patient.

In the case of *Burke vs. Chicago and West Michigan Railroad Company*, a physician who was attending an injured employee, not having been employed in the first instance by any one assuming to act for the railroad company, attempted to fix the liability upon the company by virtue of a letter which he received from the chief surgeon of the company, which was as follows: "I am informed that you are now attending —, an employee of the Chicago and West Michigan Railroad Company, who was injured a few weeks ago. Will you be kind enough to inform me as to his present condition? Has he completely recovered? I would

like a history of the case since you took charge of it. Please send your bill for services, itemized to me, if you are through with the case." It was shown by the company that the chief surgeon had no authority to employ a physician or surgeon to act generally in a case, but only to act temporarily in case of emergency; moreover, the court held, there being no original employment by a representative of the railroad company, the chief surgeon's letter could not be construed a ratification of such employment, even though ratification were authorized by him, nor could the letter be construed as a contract of employment.*

Liability of Counties and Towns for Services to Paupers.—Another prolific source of litigation is the question of the liability of counties and towns for medical services rendered to their paupers. This right is based upon statutes which differ in the several States; therefore a satisfactory treatment of the subject will necessarily be by States, and will require a greater amount of space than should be devoted to the subject in this chapter.

The various States have enacted laws calculated to afford relief to the distressed poor who through age, disease, or other infirmity are unable to provide necessary food, clothing, shelter, and medical attendance for themselves; but the extent of the class included in such charitable enactments, as well as the extent of the aid afforded them, varies considerably. In some States only those poor people are entitled to medical attention at public expense who have been formally declared paupers by the proper tribunal; while in others all persons unable to pay for necessary medical attention, whether declared paupers or not, and in some States whether residents or non-residents, are entitled to have their physicians' bills paid from the town or county treasury. In some States, if the officer whose duty it is to authorize the medical treatment of a poor person wrongfully withholds such authorization, the physician must secure authority by appeal to the proper tribunal, treat the patient at his own cost, or leave him to suffer without attention. In others he may treat the patient and sue for and recover the value of his services, notwithstanding the wrongful withholding of authority for such treatment. In case of an accident, where persons without property or ability to pay for their own medical treatment are severely injured, the physician may in some States give them immediate attention and recover from the town or county the value of such services; while in others he must leave the patient to suffer and perhaps die while he secures instructions from the overseers of the poor to render medical services, if he collects the value of such services.

The liability of the town or county for medical attendance upon prisoners confined in the county jails is also subject very largely to the regulation of local statutes.

(To be continued.)

Pith of Current Literature.

A New Method of Expelling the Placenta.
Credé's method, in which downward compression is exercised on the fundus uteri without any counter sup-

port, being not altogether free from danger, M. R. Boudberg (*Vratch; Gazette de gynécologie*, December 15th) recommends the following procedure: The abdominal wall being relaxed, one hand is placed on the fundus, the four fingers being pressed in behind it, while the thumb and thenar eminence grasp it in front. The other hand, the cubital border resting on the pubes, grasps the lower portion of the uterus, the thumb on one side, the fingers on the other. Great gentleness is requisite. When the uterine contractions begin the hands assist in the expression. The pressure must be augmented and diminished very slowly. The relaxing of the pressure especially must be slow, and never complete, but maintained to a slight extent during the intervals. These manoeuvres are repeated with every pain. When the abdominal wall is too thick, or the confinement has been premature, and it is impossible to grasp the uterus with both hands as described, the author recommends the introduction of two fingers into the vagina, when by opening them so that their tips are in the two *culs-de-sac* the necessary counter support is afforded to the downward pressure caused by the compression of the other hand on the fundus.

Use your Eyes.—Mr. Herbert Page, F. R. C. S. (*St. Mary's Hospital Gazette*, February), says that it was a favorite maxim of the late Sir George Humphry, whose memory is revered by all Cambridge men, that in clinical investigation we ought to make use of "the eyes first and much, the hands next and least, the tongue not at all." The utterances of such a man, he says, deserve to be recalled, for he was great as a surgeon, and incomparable as a teacher, of whom it has been well said that "his acknowledged pre-eminence as a teacher was mainly due to his insisting upon accuracy."

Mr. Page illustrates his meaning by two examples from a recent clinical examination, which he describes as follows: A girl about thirteen years of age had met, at the age of seven, with an injury to the right shoulder, and now presented herself with a stiff shoulder joint, and with the humerus on the affected side nearly three inches shorter than its fellow. Candidate after candidate went up to the patient, and failed to recognize this obvious difference between the two arms, some from sheer inability to observe, others because the first step of their examination was to use their hands, where-with the shoulder and the limb were immediately hidden from view. The clue to the diagnosis of this case was clearly the shortening of the limb, which a trained eye would have seen at once; and as a matter of fact the one man who quickly made the correct diagnosis of separated epiphysis did so simply because his observing eye had seen it. It will hardly be believed that one candidate was sent back four times to this patient, with an increasingly broader hint each time from the examiner what it was he was to look for, and even then he failed to see.

Again: There lay upon the table a little boy, stripped as to his abdomen and legs. One after another of the candidates proceeded to waste precious time by directing manual examination to the ankles, knees, or thighs, without even a gleam of suspicion of what was the matter with the child. And yet the eye ought immediately to have seen that the lower left quadrant of the abdomen did not move in respiration as well as the right, that there was evident fullness in this region, and that the left thigh was a trifle flexed. Had these things been

* Burke vs. Chicago and W. M. Ry. Co., 72 N. W. Rep., 907 (Mich.).

seen, examination would then surely first of all have been directed to this fullness, and accurate observation would have revealed that flexion of the left thigh as compared with that of the right was decidedly impaired. Yet no one either saw the one or detected the other. The clew was missed, and it occurred to none save one to look at the spine, and there to discover in the large angular curvature, which almost cried for recognition, the confirmatory evidence of a common or garden psosas abscess.

A Good "Christian Science Cure" Missed.—The *Medical News* for March 25th, citing the *Trained Nurse* for March, 1899, says that a woman was recently taken to the Seney Hospital, Brooklyn, suffering from what appeared to be an abdominal tumor. The surgeons examined her and fixed upon a day for operating. Just before the time set the woman arose, dressed herself, and walked out of the hospital. She had been "cured" by fright. If she had got into the clutches of a Christian Scientist another "miracle" might have been reported.

Congenital Immunity to Syphilis.—Dr. George Ogilvie (*British Journal of Dermatology*, March), in a paper on this subject, says that from the evidence adduced the following conclusions may be drawn: 1. No facts exist to prove that paternal syphilis ever confers immunity, partial or complete, upon the offspring, no matter whether at the time of procreation the father is actually syphilitic or has become immune to syphilis by previous disease. 2. No facts exist to prove that maternal syphilis in its tertiary stage confers immunity, partial or complete, upon the offspring, or that the mother's immunity to syphilis acquired by previous disease is ever hereditarily transmitted to her child. 3. It seems certain that mothers syphilitic before delivery rarely communicate the disease to their offspring in extra-uterine life. Such contamination has been observed in some cases of postconceptional syphilis. Whether it ever occurs in preconceptional syphilis we do not know.

In preconceptional syphilis two circumstances co-operate toward this result: *a.* That it is exceptional for mothers with preconceptional syphilis, who give birth to healthy viable children, to present infectious lesions after delivery, from which the child's infection could be derived. *b.* That infection by nursing, after the first year, from a woman's infection, is altogether exceptional.

In postconceptional syphilis also, two points have to be taken into consideration: *a.* That postconceptional syphilis is relatively rare. *b.* That acquired syphilis appearing in the child after the second month of life may, in not a few instances, have been mistaken for congenital syphilis, simply because the mother's syphilis dated back to a period previous to delivery.

These circumstances, taken together with the effect of timely and appropriate treatment, may explain—to a certain extent, at least, he thinks—the child's apparent immunity from infection by its mother. Whether this explanation is altogether sufficient, or whether we have to recur to the supposition of immunity to syphilis in the child, he is unable to say. This could be finally settled only by the comparison of large numbers of observations, which are at present unobtainable. If secondary syphilis in the mother confers immunity *in utero* on the child which escapes intra-uterine infection, such immunity appears to be neither constant nor lasting. To explain the so-called "exceptions" by the

late period of pregnancy at which the mother's infection takes place is, he says, an hypothesis not altogether consistent with the clinical evidence which it is meant to explain. Particular stress is laid upon this point by Hoehsinger. But Finger's table of fifty cases of post-conceptional syphilis seems, on the other hand, to demonstrate that intra-uterine infection of the fœtus may take place before the secondaries of the mother appear. There is no ostensible reason why the same should not apply to immunization, in particular if it is due to toxins, which in all probability would be present in the circulation before the appearance of the skin eruption.

The child's intra-uterine immunization by its mother's secondary syphilis he considers an interesting and ingenious theory not abundantly supported by facts. That such immunization seems to take place in some acute infectious diseases, either *in utero* or by suckling, does not, he thinks, materially enhance its probability with regard to syphilis.

Aphasia in Typhoid Fever.—Lopriore (*Gazzetta degli ospedali e delle cliniche*, January 5, 1899; *Presse médicale*, February 25th) records a case in which, on the seventeenth day of typhoid fever, when the temperature was very high, 106.8° F., the patient, a little girl ten years old, began to cry, to move her lips and tongue as though desirous of talking, and to show great distress, but was unable to articulate a word. The child understood what was said to her, and there was no paralysis of the limbs. The motor aphasia persisted a month and a half in spite of the reeducation of speech undertaken by the mother so soon as convalescence was established. The author attributes the aphasic phenomena to a septic microbial embolus of that branch of the Sylvian supplying the centre of Broca. Whatever may be thought of this explanation, says the French translator, the case deserves publication on account of its rarity.

A Case of Fatal Hæmorrhage from the Conjunctiva.—Allison J. Abbe (*Annals of Ophthalmology*, January; *Medical and Surgical Monitor*, March 15th) reports the case of a newborn babe, born at full term, but only weighing five pounds, in which death occurred on the second day from hæmorrhage from the conjunctiva. The left upper lid appeared red and swollen when the infant was bathed. This increased so that it became everted spontaneously when the eye was opened. The next morning a straw-colored discharge appeared when, by mistake, a drop of six-per-cent. instead of a two-per-cent. solution of nitrate of silver was dropped into the eye. At eleven o'clock bloody oozing began, which became a steady trickling by 3 p. m. At 4 p. m. bleeding began from the right eye. Any handling of the lids made the bleeding worse. On everting the lids the upper one had a "dark purple, rough, adherent mass" over its whole surface. The conjunctiva of the globe and the cornea were clear. The bleeding continued until midnight, when the child died. The cause of the hæmorrhage is not known. Several other cases of severe hæmorrhage from the conjunctiva have been reported.

"Huchard's Sign" of High Arterial Tension.—Huchard (*Presse médicale belge*; *Revue médicale*, March 15th) calls attention to the following phenomenon: In the normal state the number of pulsations diminishes from six to eight beats when a person changes from the vertical to the recumbent position. From numerous observations the author finds that in subjects of hyper-

tension this deviation in the pulse rate tends to disappear, and may even become reversed. When this reverse takes place it is a sign of arterial hypertension. It is asserted that by this means hypertension may be clinically measured without the sphygmograph.

Sudden Death during an Attack of Hepatic Colic.—M. Chaffard (*Indépendance médicale*, February 1st) recently reported to the *Société médicale des hôpitaux* the case of a woman forty-seven years of age who for seven days had been suffering from a violent attack of hepatic colic. She was an alcoholic, and had had numerous attacks, some grave, prolonged, and accompanied by jaundice, others mild and without jaundice. The present attack was the most severe and the longest of all. Moreover, slight jaundice had been present from the second to the fourth day, abundant epistaxis had occurred on the third and sixth days, metrorrhagia on the fourth, and there were, in addition, agitation and nocturnal delirium. The patient clamored for an injection of morphine. There was no sign of cardiac collapse and the temperature in the vagina was only 98.2° F. About a seventh of a grain of morphine was given hypodermically. Half an hour later, when the pain had been assuaged, the patient was found dead in bed. At the autopsy the liver was found normal; the gall bladder neither dilated nor atrophied, but containing a dozen calculi, large and small, and a considerable quantity of a whitish, semitransparent, viscous liquid, which, on analysis, contained neither bile acids nor pigments. A calculus as large as a dwarf pea was firmly imbedded in the duct immediately above the hepatic duct, firmly fixed, and completely obstructing the lumen. The heart was healthy, without clots, and contracted in systole. All the other organs were sound.

Was death due to reflex syncope? That is not likely, since it occurred not during the paroxysm, but after the suffering was quieted. Moreover, in syncope the heart is arrested in diastole, not systole. The most plausible explanation assigns a toxic cause for death. Several conditions concurred to lessen the resistance of the organism—alcoholism, nervous exhaustion due to seven days' suffering, anemia due to repeated hemorrhages, and self-intoxication of hepatic origin. In these conditions even a small dose of morphine may prove dangerous. To this the *Gazette hebdomadaire de médecine et de chirurgie* for February 2d adds that nervous exhaustion and hypothermia must be taken into account in cases of this kind. Morphine must either be avoided, or given according to the suggestion of M. Ferrand by adding an equal amount of ether to that of the morphine solution used.

An Experimental Study of "Visions."—Dr. Morton Prince (*Journal of the Boston Society of Medical Sciences*, December 6th and 20th), in the abstract of a paper read before the society, says that it is well known that certain persons have the faculty of creating vision at will, usually by the process called "crystal gazing", but it is not so commonly understood that "spiritistic mediums" artificially cultivate the seeing of vision by practically the same method.

Visions thus created, he says, probably do not differ in genesis from those occurring spontaneously in normal persons, and may be the product of the same psychical laws as are some of the hallucinations of the insane. In almost all observations hitherto reported it has been impossible to thoroughly investigate the relation of the

visions to antecedent events in the subject's life, beyond the waking memory of that person, but with the author's subject it was possible to hypnotize and obtain two additional and distinct personalities, and thus revive facts long forgotten by the normal personality.

The visions could be divided into three groups: *a*. Including revivals of past visual experiences, either conscious or subconscious. *b*. Others, not revivals, but largely newly created visual repetitions of past experiences other than visual. *c*. Neither revivals nor representations of past experience (visual or other) so far as known.

The mode of producing the hallucinations was to have the subject gaze into a glass bulb, when, after a few seconds, she saw various scenes acted before her.

The visions were not seen as small objects reflected in or on the glass bulb, but the bulb disappeared and the scene described appeared before her, the characters being life-size and like living persons. The visions were like ordinary hallucinations or vivid dreams, the scenes real, of life size, but dissociated from the subject's surroundings. In two experiments of the first class the vision was a representation of past experiences of the subject, but which had been forgotten. In Experiment III certain things were portrayed which the waking consciousness apparently never perceived, but which were seen by the so-called unconscious part of the mind. In Experiment IV an absent-minded and a somnambulistic act were seen in the glass. In Experiment V a complicated series of acts done in the delirium of pneumonia reappeared as a vision. Experiment VI shows how a vision may be constructed out of certain past familiar and certain other experiences of which no optical images could have been had—a new synthesis of images being created by the force of imagination and known facts. Experiment VII probably represented something she had read, etc.

The author draws the following conclusions:

1. Visions in sane persons may be revivals of past visual experiences which originally may have been conscious or subconscious. The original subconscious experience may have occurred in a moment of absent-mindedness, or may not have been sufficiently intense to have entered consciousness, or (rarely) may have occurred in somnambulism.

2. The vision, instead of being a revival, may be a newly created pictorial representation of a past experience other than visual. That is to say, past impressions of one or more senses (touch, hearing) and actions may translate themselves into representation by another sense as a vision.

3. It is probable, though not proved, that a vision may not reproduce or represent any past experience, visual or other, but may be newly created out of something the subject has read, heard, or thought. The inference from, and passing thoughts about, known facts may weave themselves into visions. This was probably the origin of the visions of Joan of Arc and religious enthusiasts.

4. Visions may partake more or less of the characteristics of these classes, being partly revivals, partly representations of actual non-visual experiences, and also of the subject's knowledge, inference, and thoughts.

5. Generalizing, it is possible that hallucinations of the other senses, especially of hearing, and such as are exhibited by trance mediums, may have a similar origin and composition.

6. Analogous phenomena may be observed in the

attacks of hysterics where the passing thoughts in the normal state may appear as insistent ideas in the attack.

7. It is probable that thoughts which have strongly absorbed the mind and expressed the longed-for ambition or ideas and beliefs of the subject may appear as visions. The subjects are then apt to look upon them as inspirations. In this way may have arisen the visions of political personages like Joan of Arc, Bismarck, and religious enthusiasts like Luther, Peter the Hermit, Catherine of Sienna, and others.

8. Visions, artificially created, may be representations and revivals of the experiences of the hypnotic personality, of which experience the waking consciousness never has had knowledge.

9. Impressions on the sense organ which never entered consciousness (and were therefore never known or remembered) may afterward appear as visions.

Three Cases of Congenital Deficiency of Both Patellæ in Related Individuals.—In our issue for February 18th we quoted a case of congenital deficiency of both clavicles. Dr. Maurice G. Pearson (*Lancet*, January 28th) now records three cases of colored children which illustrate different degrees of deficiency of the patellæ and are interesting as showing the extent to which growth is an element in its cure. The first two are the only children of one father, while the third is the child of his brother and has several brothers and sisters whose patellæ are natural. *Case 1:* In this patient, a girl, aged five months, there is a very noticeable transverse groove in the position of each patella, and the finger can be pressed in deeply between the condyles of the femur; the patella itself can be felt as a nodule about a third of an inch in diameter; the quadriceps tendon and ligamentum patellæ are narrow, cordlike bands. Although, of course, the child is as yet unable to walk, she can extend her knee quite well. The movements and limits of movements are natural. *Case 2:* A sister of the above, aged four years, has now patellæ which are only slightly smaller than the average. The interesting point about her is the fact that her mother says her knees were as an infant exactly like her sister's, that she was very long in learning to walk, and that even now she can not walk for long, and is "shaky on her legs." *Case 3:* A cousin of the others, aged seven months. This girl also has very small patellæ, but not so small as Case 1. She has also the transverse groove less well marked. Unfortunately, the author was not within reach of any skiagraph apparatus.

How to Induce Local Anæsthesia by Cataphoresis of Cocaine.—Dr. H. Lewis Jones (*Clinical Journal*, March 8th) describes this process as a means of local anæsthesia for trivial operations as follows: "Dr. Morton, of New York, who has recently brought out an admirable book upon the whole subject of the introduction of drugs through the skin by electrical means, has published a formula for a solution of cocaine in guaiacal with which it is much easier to produce a local anæsthesia than it has been hitherto with watery solutions. The solution he recommends consists of cocaine (the alkaloid, not the hydrochlorate), six grains, dissolved in a drachm of guaiacal. If a little of this mixture upon a piece of blotting paper is placed on the skin, and a current applied through it, the cocaine quickly penetrates, and an anæsthesia sufficient for the purposes which I have indicated can be produced in about four or five minutes. The positive electrode should be placed on the blotting paper. It should consist of a

flat disc of bare metal of suitable size. A platinum surface is the best, but tin or any other metal which does not easily become corroded will do almost as well. Care must be taken that the metal itself does not touch the skin at any point. The current is then turned on until it reaches about four milliamperes for an electrode half an inch in diameter. At first from ten to fifteen cells are necessary to produce this current, for the solution has a high resistance; but soon conduction improves, and the number of cells may be reduced. A slight pricking pain is felt during the first minute of the application, but this gradually passes off, and its disappearance indicates that the drug is commencing to act. It is not necessary to prolong the action more than four or five minutes, nor should the current much exceed four or five milliamperes for the above-mentioned size of anode, because the solution itself is slightly caustic, and may produce a superficial irritation if applied for too long a time. The blotting paper being removed, and the part wiped with a tuft of cotton wool, the operation may be commenced. Common sensation may not be entirely done away with, but the perception of pain is so nearly abolished that the patient will bear the introduction of a needle with calmness."

The Mode of rising from the Sitting Posture as a Diagnostic Aid.—Bédart (*Echo médical du Nord*, December 11, 1898) concludes a careful observation (accompanied by schematic representations) on this subject as follows: 1. There are two series of characteristic attitudes adopted in rising by the patient of sciatica and the patient of lumbago or other lesion of the lumbar region—*e. g.*, vertebral caries, contusion, etc., respectively. 2. These objective signs are of some importance in certain cases, especially in simulation, of lumbar troubles and sciatica. In lumbar diseases the patient, when seated on the ground and told to rise, takes his point of support from the hands placed on the ground toward the point, so as to attain the intermediate position "on all fours," as is the case in pseudo-hypertrophic paralysis. In sciatica, on the other hand, the patient takes his support from the hands placed on the ground behind the body and passes therefrom through a squatting posture toward the erect position. Before applying this test, it is advised that the arms of the patient should be crossed and the thighs extended parallel to each other.

The Effects of Oophorectomy on the Female Organism.—A. Pfeifer (*Münchener medicinische Wochenschrift*, 1898, p. 1619; *Gazette hebdomadaire de médecine et de chirurgie*, March 5th) reports that a hundred and sixteen women who had been subjected to oophorectomy were examined with a view to ascertain the effects upon menstruation, sexual desire, alteration of the genital organs, the general health, the nervous system, the psychical condition, and also the therapeutic effects with the following results: The operation was followed by the menopause in 91.8 per cent.; sexual desire—that is, the enjoyment of the sexual act—remained in twenty-six cases (22.6 per cent.), was diminished in thirty cases (24.4 per cent.), and extinguished in forty-three cases (52 per cent.). The uterus regularly atrophied, while the vagina and vulva were only rarely affected. Hysteria was a frequent result, as also was a tendency to obesity. The voice often remained disagreeable, at least for some time after the operation. The therapeutic results had been particularly satisfactory. The essential troubles had disappeared in eighty-seven cases, in eighteen cases they were sensibly ameliorated, and in

six others less so. The operation was specially successful in myoma and in dysmenorrhœa.

Removal of an Ovarian Tumor during the Acute Stage of Typhoid Fever.—Dr. E. W. Cushing (*Annals of Gynecology and Pædiatry*, March) records the following very interesting case of a girl eleven years and ten months of age who had always been healthy; she had never menstruated. For a year before the time of operation she had been nauseated nearly every day, mostly at noon, the attacks of nausea not lasting long. For three months previous to operation she had had feelings of weakness and faintness at intervals, such attacks usually coming on in the afternoon. During six months before operation the mother had noticed enlargement of the abdomen, slight at first, subsequently growing rapidly.

Two weeks before this patient was taken sick, her sister in the same house was seized with severe typhoid fever, with all its well-known and pathognomonic symptoms. This patient began to droop on Tuesday, April 12, 1893. She did not take to her bed until Friday, when she became violently ill, with temperature running to over 105° F. in the evening.

As the abdominal swelling was great and the respiration was very much impeded by it, Dr. Cushing was sent for by the physicians in attendance on the same day in the hope that surgical measures would afford some relief, perhaps by tapping. Examination of the patient showed an ovarian tumor, round, smooth, movable, and fluctuating, which led Dr. Cushing to attribute the high temperature to typhoid fever, inasmuch as her sister was already infected with that disease. At any rate, he preferred opening the abdomen to puncturing without knowing what he had to deal with.

The operation took place on Monday, the seventh day after the first signs of indisposition, and the third since she had been in bed. Rose spots could be detected pretty clearly. The whole abdomen was filled with a fluctuating mass. Temperature, 101° F. Breathing very shallow and difficult. Incision revealed a clear, shining cyst wall, which was punctured and the fluid evacuated. There were no adhesions. The other ovary also showing signs of cystic degeneration, was removed. The operation was particularly easy and correspondingly rapid. It was a peculiar sensation to put the hand into an abdomen at a temperature over 101° F. It felt actually hot. Dr. Cushing examined the small intestines carefully to see whether any disease of Peyer's patches could be detected by sight or touch, thinking that the opportunity in the living subject would not often occur, but no abnormalities could be found in the intestines.

The patient recovered nicely from the operation, but had a long and hard struggle with the fever. The oppression of breathing was relieved at once. There were thirteen hæmorrhages from the intestine, on the second day thirteen days after the operation. It seemed as if she would hardly recover, but youth and good care finally brought her through, although she was ill for over three months. She lost all her hair, and went through a perfect wreck. There was at no time any suppuration of the abdominal wound.

The young lady finally made a most perfect convalescence, and has developed into a handsome, active, intelligent physical and mental vigor, and is now nearly eighteen years old. As it is not often that the ovaries are removed before puberty, Dr. Cushing adds, it may

be interesting to state that in no respect whatever does this girl seem, or, so far as can be ascertained in such a delicate matter by her mother, does she feel, at all different from other girls of her age.

Sarcoma of Both Ovaries.—Mr. Alban Doran (*Transactions of the Obstetrical Society of London* for October, November, and December, 1898) recently showed to the society two sarcomatous ovaries removed from a woman forty-five years of age who had been five times pregnant. Her last pregnancy had ended in an abortion at the third month, in June, 1898. A swelling was then felt above the pubes, and increased very rapidly. The periods remained regular, though the show was never free. Two lobulated tumors filled the abdomen from the pubes to two inches above the umbilicus. They felt very elastic, and anteriorly was a cystic projection simulating a dilated bladder, but the catheter only passed four inches and not near the cyst. The cervix was high, and the left tumor came down behind it in Douglas's pouch. The uterine cavity measured three inches and a half. The two tumors and the uterus moved together, but were not very movable. Taken as a whole, Mr. Doran thought that the tumors were uterine. At the operation some deep-red ascitic fluid escaped, and then on drawing out the right tumor he found that it was attached by a short but anatomically normal ovarian pedicle to the right side of the uterus. There were intimate and very vascular adhesions to the small intestines. The left tumor was more solid than the right, and its pedicle was anatomically normal, but with extremely dilated vessels. Neither pedicle seemed infected with the new growth, but both were short. The two tumors weighed five pounds fifteen ounces, and looked like myxo-sarcomatous growths. On section they appeared reddish brown and gelatinous like a kidney, or still more like a polished red pebble. The patient recovered, and was in good health on January 2, 1899.

Mr. Doran has seen a large number of these doubtful solid and semi-solid tumors. As a rule, he says, diagnosis is not attended with difficulty, but lobulated soft solid ovarian growths with short pedicles can not always be distinguished from multiple uterine fibroids without the aid of an exploratory incision. Clinical and physical symptoms are very misleading. He dwells on the question of incision because he considers it the right step. Waiting may result in a correct diagnosis, but should the tumor prove to be an ovarian sarcoma the patient will be clearly exposed to increased risk by such delay.

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of December 7, 1898.

The President, Dr. S. ALEXANDER, in the Chair.

(Continued from page 506.)

Intra-uterine Vaporization.—Dr. A. BROTHMAN read a paper on this subject, and exhibited the apparatus used in conducting the treatment.

Dr. W. J. CUNNINGHAM, of St. Louis, said that mention had been made in the paper of obliterating

the uterine cavity as a cure for salpingitis. He thought if the ovaries were left *in situ* it might be unwise to completely close the canal.

Dr. BROTHERS said that many operators, when they found bilateral disease of the annexa, made it a rule to remove the uterus at the same time, on the plea that the uterus being diseased is apt to give rise to subsequent symptoms. If the canal of the catarrhal uterus could be obliterated, then the only reason for removing the uterus in such cases would be removed. He had not intended to say that this procedure was a cure for salpingitis.

Mistakes I have made in the Diagnosis of Appendicitis.—Dr. ROBERT T. MORRIS read a paper with such a title. (See page 469.)

Dr. JOSEPH D. BRYANT said that any one who operated for appendicitis was very liable to be mistaken in the diagnosis. He recalled the case of a young and well-nourished lady, of hysterical temperament. She had come under his charge two years ago. Careful examination had shown the presence of a small tumor, associated with deep tenderness and fever. He had agreed in the diagnosis of appendicitis made by her family physician, but she had declined operation. She had returned six months later with the same condition, and he had operated. Not only had there been no appendicitis, but she absolutely had no appendix. That she was hysterical had been recognized, but the point of tenderness was found to be a glandular growth located posterior to the usual site of the appendix. As the patient had been told that the appendix had been removed, she had recovered promptly, and had had no further trouble of this kind. Another case was cited to bring up the question of diagnosis in connection not only with hysteria but with alcoholism. About eighteen months ago he had seen in Bellevue Hospital a man of middle age suffering severely from the effects of a debauch. There was deep tenderness over the region of the appendix, although he asserted that the appendix had been already removed by a competent surgeon in this city. Three or four months afterward he said that he had had another attack, coming on as had the first one, after excessive drinking. He had then been operated upon in another hospital, and had been informed that "a piece of diseased tissue had been removed." When seen at the Bellevue Hospital, he had been suffering from a third attack. There had seemed to be more than the usual tenderness, so that Dr. Bryant said he had been suspicious that hysteria was the underlying condition from the beginning. He had subsequently learned from the surgeon of a Brooklyn hospital that the man had been in that hospital suffering from the effects of a debauch, and also symptoms of appendicitis. Dr. Bryant then spoke of finding fibrinous peritonitis with malignant disease of the caecum. In the first case of this kind that he could recall, a part of the ileum had been excised by an eminent surgeon, and the patient had recovered. The subsequent examination of the specimen had revealed a diseased appendix and a large amount of surrounding lymph which had been mistaken for a sarcoma. Two years ago he had seen a patient with a very large tumor in the ileo-caecal region. Believing that the patient was suffering from appendicitis, another surgeon had made a free incision. A mass had been disclosed which was thought to be a sarcoma, and accordingly the wound had been closed. Two or three months later the case had come under Dr. Bryant's care. The history stated

that after the primary operation most of the induration had disappeared, but that it had subsequently returned. A free incision into this large mass of lymph had disclosed an appendix, about four inches long, containing no foreign material, but the wall was thickened. Microscopical examination by Dr. Dunham showed that this was the result of chronic inflammation. The speaker said that it not infrequently happened that one had another attack of appendicitis after one appendix had been removed, or was said to have been extirpated.

Dr. PARKER SYMS said that while a typical case of appendicitis was easy to diagnose, one should not lose sight of the fact that cases of fulminating appendicitis seen before the signs of peritonitis had developed might be easily looked upon as those in which the diagnosis of appendicitis had been erroneous. Certainly there was often a brief period of quiescence before general sepsis sets in. These cases often presented no evidences of their gravity until serious mischief had been done. He had frequently operated in cases of appendicitis in the interval, but never under such circumstances assumed the responsibility for the diagnosis, as it must necessarily depend upon the previous history entirely. So far it had been his good fortune not to have operated upon a normal appendix. He had removed appendices in the interval which had presented externally nothing unusual except slight congestion, but further examination had shown more or less obliteration or a more or less active catarrhal process going on within the appendix. For this reason it was sometimes more difficult to make the diagnosis of appendicitis after making the incision than before beginning the operation. In two instances he had met with large masses of lymph resembling a neoplasm, but had proved the true nature of the condition by exposing the mass thoroughly and removing the imbedded appendix. In one case, thought to be periappendicular abscess, seen about the tenth day of the attack, the operation had disclosed a fixed kidney. He was unable to account for the subjective symptoms.

Dr. N. E. BRILL congratulated Dr. Morris on his exceptional good fortune in not meeting many cases of appendicitis in which the diagnosis was in doubt. He had a rarer good fortune than most clinicians who, though more accustomed to abdominal palpation, meet the most of the cases of appendicitis before the surgeon, and yet are often disturbed by a difficulty in coming to an absolute diagnosis. He could say that, so far as his experience went, the mistakes which he had encountered had been made chiefly by prominent surgeons. Two cases which were instructive he could recall at the spur of the moment. The first case which he would mention was diagnosed as an appendicitis. When it came to operation it was found that the right iliac fossa was occupied by a dense, large mass which proved to be a tuberculous omentum which had become twisted by adhesions. The other case was one giving a history of prolonged diarrhea at first, followed some time afterward by severe pain in the right iliac region, and accompanied by a mass which extended upward toward the liver. The pre-operative diagnosis had been an appendicitis with pus burrowing upward. The operation, however, disclosed an empyema of the gall bladder.

It seemed to him that while Dr. Morris was very fortunate in making but seven errors in two hundred and eight consecutive cases, he might have diminished his errors by two, for in the two cases which Dr. Mor-

ris related, one of measles and one of typhoid fever. The mistake might have been avoided. In the case of measles, inflammation of the serous membranes was not a very uncommon complication or sequela, and the peritonitis in that case might have been recognized by Dr. Morris as such a feature. As to the typhoid-fever case, the clinical history and the presence of the Widal reaction would have been sufficient. However, such a thing as typhoid ulceration of the appendix was not so rare as to escape diagnosis.

Dr. A. B. JOHNSON thought it was a cause for congratulation that Dr. Morris had made so few errors in diagnosis; certainly he had himself made more. He had personally failed to make the diagnosis of appendicitis during the first twelve or eighteen hours of the disease on account of the absence of any tenderness in the right iliac fossa. The mistake was perhaps less likely to be made by the surgeon than by the physician. In another case he had made a mistake in judgment. The patient was a young man who had presented the characteristic symptoms of appendicitis for one week. He was apparently getting better at the first examination—the temperature was not over 99.5° F., and the pulse was not rapid, although he looked ill, and there was some yellowness of the conjunctiva. Operative interference had been accordingly postponed for a few days, but owing to the persistence of the temperature operation was performed. It disclosed a small encysted abscess communicating with a gangrenous appendix. The wound did well, but the man became more and more yellow, developed ascites, and died of a septic phlebitis. He had heard of a few similar cases in which it was probable that an earlier operation might have saved life. He had operated for supposed appendicitis, and had found an inflamed gall bladder. Just before this he had operated in a case in which the appendix had been situated very high up. The gall bladder in the second case was found to be inflamed, and full of stones and pus. However, the patient had made a good recovery. Two days ago he had made a mistake in the case of a woman giving a history of a tumor in the lower part of the right side of the abdomen for four or five years. There were symptoms pointing to acute appendicitis. The extreme tenderness prevented a searching examination. On the right side of the vagina was an elastic swelling which seemed to correspond with the tumor referred to. The tumor in the iliac fossa was tympanitic. On making an incision it was found that there was a very large abscess full of pus and gas. The appendix had already sloughed away. Three times he had operated for supposed appendicitis and had found peritonitis, due to pus tubes in two cases, and to gangrene from twisting of the tube in a third case. He agreed with Dr. Syms that the external appearance of the appendix was often misleading. A few days ago, in a case of very short duration, the appendix did not seem to be even congested, but after its removal examination showed that perforation at one point was imminent. Dr. Johnson also spoke of a rather puzzling class of cases in which a long appendix extended across the abdomen, and the signs were located on the left side. He had operated in two such cases in the past fortnight. In one of them the signs had been entirely on the left side, and the abscess had also been on that side. An incision having been made to the left of the median line, it had become necessary to make another on the right side to remove the appendix, which was about five inches

long. In the other case, the signs had also been entirely upon the left side, and there had been a decided difference of opinion among the surgeons who had seen the case, particularly as there had been a large mass on the left side. The operation had revealed a large mass of intestines glued together by lymph. On the other side there was a long appendix perforated at its tip, and communicating with an abscess a little to the left of the median line. It was a question whether the median incision should be used in these cases or an incision made first on one side and then on the other.

Dr. CHANDLER asked whether the presence of fever was necessary to diagnose appendicitis. He would also like to know the differential diagnosis between colitis and appendicitis, and if, in the absence of fever and including any disease of the abdominal walls, pain located only at "McBurney's point" should be considered an indication of the existence of appendicitis.

Dr. ALEXANDER asked regarding the case in which the appendix had been found adherent to the ovary, whether the adhesions had resulted from disease in the ovary or in the appendix. In illustration of the mistakes in diagnosis he recalled the case of a lady from whom he had removed a calculus located in the ureter. In her case a diagnosis of appendicitis had been made by three different surgeons outside of New York city. She had hydronephrosis, which required a nephrotomy and the removal of the stone from the ureter. This operation had only partly relieved her of her pain. Subsequently another surgeon had removed her appendix, and she had since then been entirely well.

Dr. MORRIS said that in most of the cases in which there were large masses of lymph exudation there had been a mucous inclusion and infection, the lymph being there for the purpose of guarding against further infection. Sometimes an appendix would be bent in such a way that one part would be firmly adherent to the cæcum and another part be free. He had recently operated in such a case in which the adherent part of the appendix was three inches long, and contained a very large concretions. A surgeon had previously operated upon this patient, and his testimony had been corroborated by several witnesses, that he had removed a gangrenous appendix, four inches long, and that it had contained two concretions. At the time the speaker had operated there had been three inches of the appendix imbedded in very dense adhesions. It was probable, therefore, that four inches of free appendix had been cut off at the first operation, and that several inches of adherent appendix had been overlooked at that time. It was the latter which had been extirpated at the second operation. Regarding the interval cases, Dr. Morris said that he did not operate unless there was distinct evidence, on palpation, that the appendix was infected. It was not difficult to learn to palpate inflamed appendices in the interval, or even to palpate normal appendices. In many of these cases, one or two concretions could often be made out in the interval. Where the appendix looked normal, and yet there was a distinct history of an acute attack, and internal tenderness on palpation, there was sufficient justification often for operation. Allusion had been made to cases in which the only abnormal appearance of the appendix is a dilatation of the vessels on the outside; this, he thought, was an anatomical peculiarity only. On examining the adjacent bowel and mesentery it would be found that these dilated vessels were present there also. As to the error in diagnosis in the case following typhoid fever, it

should be said that the typhoid fever had not been typical, and the presence of another eruption had made it more than usually difficult to establish the diagnosis. A gall bladder distended with stones not infrequently occupied the region of the appendix, as did also the kidney, but in all that he had seen the gall bladder and the kidney had been movable, enabling a correct diagnosis to be made. In the left-sided cases he had usually made a short incision, first on the left and then on the right side. Robinson, of Chicago, had shown how the psoas muscle sometimes caused traumatism of the sigmoid, giving rise to an inflammation of this portion of the bowel. The case of adherent tube and appendix was, in all probability, one of salpingitis, the disease having involved the appendix. In answer to Dr. Chandler, he would say that at the outset of an appendicitis there was apt to be a mixed infection, and this was usually associated with a temperature of from 101° to 104° F., but very soon the colon bacillus obtained supremacy, and its toxins did not usually cause much fever—a typical colon-bacillus temperature was from 99° to 101° F. Of course, if the other bacilli continued to be active, the temperature would be quite high. The temperature was really of no consequence in aiding one in making the diagnosis of appendicitis. The differential diagnosis between colitis and appendicitis he made entirely by palpation. Pain at McBurney's point was not sufficient for a diagnosis; there must be also collateral testimony, such as the evidence furnished by palpation.

Miscellany.

The Medical Hero of Santiago.—Under this heading the *British Medical Journal* for March 18th has the following appreciative account of our doctor general:

"General Leonard Wood, the hero of Santiago, began his career as a member of the medical profession, and the work of sanitary regeneration which he has begun in Cuba has doubtless been inspired and directed by his medical training. Governor Roosevelt has contributed to the *Outlook* an interesting sketch of his early career. General Wood, he says, was a Cape Cod boy, and to this day there are few amusements which he enjoys more than for himself to sail a small boat off the New England coast, especially in rough weather. He went through the Harvard Medical School in 1881-'82, and began to practise in Boston, but his was one of those natures which, especially when young, fret for adventure. A year after leaving college he joined the army as a contract surgeon, and almost immediately began his service under General Miles in the southwestern territories. These were then harried by the terrible Apaches; and the army was entering on the final campaigns for the overthrow of Geronimo and his fellow renegades. No one who has not lived in the West can appreciate the incredible fatigue and hardship attendant upon the campaigns. There was not much fighting, but what there was of an exceedingly dangerous type; and the severity of the marches through the waterless mountains of Arizona, New Mexico, and the northern regions of Old Mexico (whither the Apache bands finally retreated), was such that only men of iron could stand them. But the young contract doctor, tall, broad-

chested, with his light yellow hair and blue eyes, soon showed the stuff of which he was made. Hardly any of the whites, either soldiers or frontiersmen, could last with him, and the friendly Indian trailers themselves could not wear him down. In such campaigns it soon became essential to push forward the one actually fitted for command, whatever his accidental position might be; and Wood, though only a contract surgeon, finished his career against the Apaches by serving as commanding officer of certain of the detachments sent out to perform peculiarly arduous and dangerous duty; and he did his work so well, and showed such conspicuous gallantry, that he won the most coveted of military distinctions—the medal of honor. Wood never called upon others to do anything that he himself did not do. They ran norisk that he did not run; they endured no hardship which he did not endure—intolerable fatigue, intolerable thirst, never-satisfied hunger, and the strain of unending watchfulness against the most cruel and dangerous of foes—through all this Wood led his men until the final hour of signal success. When he ended the campaigns he had won the high regard of his superior officers not merely for courage and endurance, but for judgment and entire trustworthiness. Of General Wood's brilliant services in Cuba this is not the place to speak; they are writ large in the recent history of his country."

Prohibition of Testimony by Physicians.—The *Medical News* for March 25th states that on March 13th Governor Roosevelt signed an amendment to the civil code which had passed both houses at Albany. This amendment absolutely prohibits a physician from divulging any information he may have acquired in his professional capacity concerning any patient, either before or after the latter's death. For a long time the insurance law has permitted a physician to testify concerning the physical condition of a policy-holder.

A Traveler from Altruria.—We quote the following from the *American Druggist* for March 25th. While there is undoubtedly some truth in it, we can not help feeling sure that the view taken by the traveler from Altruria is more pessimistic in all respects than the circumstances actually warrant.

"Said a member of an essential oil firm: 'What is the use of making a pure oil of sandal? Nobody wants it. Nobody will buy it. There isn't any market for it in America. You can't induce a wholesale druggist to touch it, and the retailers do not evince the slightest interest in it. What they want is a sophisticated article upon which they can make a great big profit.'

"But what about the physicians?' the traveler asked. 'Surely they demand an oil which will effect a speedy and radical cure!'

"My dear friend!' the essential oil man exclaimed, 'do you imagine you are still living in Altruria? The physicians of that fantastic country possibly may desire to make speedy and radical cures—but, believe me, that kind of physician does not exist in America. What the Yankee doctor desires is something which will be neither radical nor speedy. Do not delude yourself with the notion that physicians in this country are pure and unadulterated philanthropists. Not on your life! They run their little *Schützenfest* for what there is in it—same as I run mine.'

"But," objected the traveler, 'you can not surely mean that you have no other consideration in your busi-

ness than that of immediate profit! I am informed that your house is one of the greatest in the line in America.'

"Oh, as to that!" the essential oil man responded serenely, 'I assure you we are very careful of our reputation. But, as one of the ancient philosophers remarked, "When a citizen of a state exceeds his fellows in virtues, he is no longer a citizen of that state." Mark Twain boiled that idea down into, "Be good and you'll be lonesome." Sabby?'

"Which I must take to mean," said the traveler sadly, 'that the essential oil business is carried on upon lines of exceeding shadiness.'

"Essential oil houses, my interesting friend, supply the wholesale druggist with that which he demands. The wholesaler gives the retailer what he asks for. The retailer is equally complaisant with the physician. You must start the reform with the doctor. Then, as the nursery rhyme has it, the stick will beat the dog, the dog will worry the pig, the pig will cross the stile, and so the old woman will get back to Altruria to-night, all right. Call again; I find your Altrurian point of view quite entertaining."

The Prevalence of Leprosy in the United States.—Dr. Prince A. Morrow, of No. 66 West Fortieth Street, is desirous of obtaining complete statistics of leprosy in this country, to be incorporated in a report on the subject. He respectfully requests any physician who has personal knowledge of a case or cases to communicate the facts to him within thirty days. Such information will be duly credited, and, if desired, the name and any circumstances which might lead to the identification of the leper will be regarded as strictly confidential.

The New York Academy of Medicine.—At the last regular meeting, on Thursday evening, the 6th inst., the following papers were presented in a discussion on malaria: Researches of the Etiology of the Texas Cattle Fever, and its Bearing upon Malaria, by Dr. Theobald Smith, of Harvard University; The Present Status of the Inoculation Theory of Malaria, by Dr. Walter B. James; and African Black-Water Fever, by Dr. F. P. Lynch, late of the Congo Free State.

At the next regular meeting, on Thursday evening, the 20th inst., in the continuation of the discussion on malaria, the following papers will be read: The Morphology of the Malarial Organism, by Dr. James Ewing; Malarial Nephritis, by Dr. W. S. Thayer, of Johns Hopkins University; and Some of the Less Common Effects of Malaria, with Remarks upon the Treatment of Chronic Infection, by the president of the academy, Dr. William H. Thomson.

At the next meeting of the Section in Surgery, on Monday evening, the 10th inst., Dr. Robert Abbe will report a case of anastomosis of Stenson's duct, and Dr. John B. Walker will report one of epithelioma of the lip in a woman. The following papers will also be read: General Prognosis in the Injuries of the Spinal Cord, by Dr. P. R. Bolton; and Fortifying the Inguinal Canal with Silver Wire in the Operation for Hernia, by Dr. A. M. Phelps.

At the next meeting of the Section in Genito-urinary Surgery, on Tuesday evening, the 11th inst., Dr. Paul Thorndike, of Boston, will read a paper on The Diagnosis and Treatment of Rupture of the Bladder; Dr. Edward L. Keyes, Jr., will present a modified conical

steel sound; and Dr. Ferd. C. Valentine will exhibit a simplified cystoscope. Patients will be presented and specimens will be exhibited.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 13th inst., the following papers will be read: A Series of Cases of Goitre in Children, including Examples of Cretinism, Basedow's Disease—Tachycardia, by Dr. Charles Hermann; A Case of Intussusception, by Dr. William P. Northrup; A Case of Abscess of the Lung following Pneumonia; Resection of Ribs; Recovery, by Dr. B. Van D. Hedges; Crescent Malaria, by Dr. Henry Heiman; and Enlarged Liver and Spleen in Infancy, by Dr. W. N. Berkeley.

Appointment to State Board of Health.—We learn from the *Medical News* for April 1st that Governor Roosevelt has appointed Professor Walter Francis Wilcox, of Cornell University, a member of the State board of health.

The Teaching of Tropical Medicine.—The *Journal of Tropical Medicine*, of London, announces in its March number that lectureships on tropical medicine are to be instituted in the University of Aberdeen and Edinburgh University.

Traction for the Relief of Pain.—At a meeting of the Section in Orthopaedic Surgery of the New York Academy of Medicine held on February 15th Dr. T. H. Myers related the case of a man, twenty-six years old, who had suffered for five years and a half with rheumatism in the ankles, the neck, the shoulders, the elbows, the wrists, and the right hip. The movements in the affected hip had become much restricted. A short traction splint was applied, and the man had had no pain since last June. Dr. S. Ketch recalled a case in which pain due to a sarcoma of the femur had failed to be relieved by powerful narcotics, but had yielded for a time to traction.

A New Chicago Journal.—The second (March) number of a new bimonthly, the *Western Clinical Recorder*, edited by Dr. F. Jenner Hodges and Dr. William T. Rinehart, contains much valuable and readable matter, and is well illustrated. The new journal will doubtless succeed.

The American Medical Association.—Dr. William B. Atkinson, the secretary, announces that the fifteenth annual meeting will be held in Columbus, Ohio, on Tuesday, Wednesday, Thursday, and Friday, June 6th, 7th, 8th, and 9th. The delegates shall receive their appointment from permanently organized State medical societies and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical departments of the army, navy, and Marine Hospital Service of the United States.

Each State, county, and district medical society entitled to representation shall have the privilege of sending to the association one delegate for every ten of its regular resident members and one for every additional fraction of more than half that number; provided, however, that the number of delegates for any particular State, territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the code of ethics of the association.

Members by application shall consist of such members of the State, county, and district medical societies entitled to representation in the association as shall

make application in writing to the treasurer, and accompany said application with a certificate of good standing, signed by the president and secretary of the society of which they are members, and the amount of the annual membership fee, five dollars. They shall have their names upon the roll and have all the rights and privileges accorded to permanent members, and shall retain their membership upon the same terms.

Each delegate or permanent member, when he registers, is requested to record the name of the section, if any, that he will attend, and in which he will cast his vote for section officers.

Secretaries of medical societies, as designated above, are earnestly requested to forward lists of their delegates at once. Also, that the permanent secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the secretaries are, by special resolution, requested to send to him annually a corrected list of the members of their respective societies.

Persons who desire to read papers before the Section in *Materia Medica*, *Pharmacy*, and *Therapeutics* at the Columbus meeting, June 6th to June 9th, are urged to send their names and the titles of their papers at once to the secretary, Dr. Leon L. Solomon, No. 323 West Walnut Street, Louisville, Kentucky, who is now making up the final programme.

The Cornell University Summer Medical Courses.—It is announced that during the coming summer the university will begin its summer medical courses in New York. The courses will last from May 15th to August 1st. They will consist largely of laboratory and clinical work, and will be open to both undergraduates of other schools and graduates, thus constituting a valuable addition to New York's resources in post-graduation instruction. The teaching corps consists of thirty-five instructors, and it strikes us that they have been very judiciously selected.

Small-pox on the Mexican Frontier.—The senseless panic in Laredo is thus described in a letter from Acting Assistant Surgeon Hamilton, of the Marine-Hospital Service, printed in the *San* last Sunday:

"The State health officer took charge and he had to call on United States troops for assistance, as the people would not be moved. The assistant city marshal was wounded on Sunday, March 19th, while trying to keep an ambulance at work, and the ambulance had to stop, as there was too much excitement, and the mob was large and beyond the control of the Texas Rangers and city police. The State health officer needed more force, and one troop of the Tenth United States Cavalry was put at the service of the mayor. On Monday, March 20th, when the ambulance commenced to move out patients, the mob again became uncontrollable and the captain of the State Rangers was wounded, and one of the leaders of the mob was killed and several others were wounded. The troops were called upon and responded at once, cleared the streets, and there has been no disturbance since. Notwithstanding all this trouble, the vaccinating corps, of which I took charge for a thorough house-to-house inspection and vaccination, have had very little opposition. There have been about twelve to fifteen refusals, which had to be reported, arrested, and then vaccinated; otherwise no trouble. There have been over thirteen hundred vaccinated or revaccinated since I commenced, and there would have been more,

only I had my corps stop work when any fighting was going on for fear that some of them might be injured. My force is not large enough, but it is all the city said they could afford at present."

The Medical Society of the State of Tennessee.—The sixty-sixth annual meeting will be held in Nashville, on Tuesday, Wednesday, and Thursday, April 11th, 12th, and 13th, under the presidency of Dr. Thomas H. Marable, of Clarksville. In addition to the president's address, the preliminary programme contains the following titles: The Subcutaneous Rupture of Large Arteries from Contused Wounds, by Dr. Jeremiah A. Crook, of Jackson; Immunity and Susceptibility, by Dr. Isaac A. McSwain, of Paris; Abscess of the Liver, with a Report of Cases, by Dr. Maximilian Goltman, of Memphis; The Hippocratic Oath, by Dr. Andrew M. Trawick, of Nashville; Tubal Pregnancy, with a Report of Cases, by Dr. James M. Black, of Knoxville; The Treatment of Acute Pelvic Inflammation in Women, by Dr. Hamilton R. Coston, of Fayetteville; The Non-operative Treatment of Appendicitis, by Dr. Edgar L. Gleaves, of Nashville; The Fever in the Mountains of Upper East Tennessee, by Dr. Hugh C. Chance, of Tazewell; The Abuse of Quinine in Malarial Hematuria, by Dr. Joseph F. Griffin, of Tiptonville; Vesical Calculus in Women, by Dr. Thomas H. Happel, of Trenton; Typhoid Fever and its Treatment, by Dr. George C. Morris, of Savannah; Choreia, with a Report of a Case complicated by Pregnancy, by Dr. Thomas W. Gallion, of Dandridge; The Treatment of the Effects of Grippe on the Prostate and Bladder of Old Men, by Dr. A. B. Hansard, of Twinville; Melancholia, by Dr. Barton W. Stone, of Nashville; Diphtheria, with a Report of Cases Treated with Antitoxine, by Dr. C. M. Sebastian, of Martin; A Practical Suggestion regarding Amputations of the Foot, by Jeremiah L. Crook, of Jackson; The Duration of Gestation, by Dr. Sidney S. Crockett, of Nashville; The Physiological and Therapeutic Effect of Static Electricity, by Dr. George P. Edwards, of Nashville; Some Interesting Cases in Rectal Surgery, by Dr. A. Bennett Cooke, of Nashville; Four Cases in Abdominal Surgery, by Dr. Thomas J. Crofford, of Memphis; The Medulla as a Speech Centre, by Dr. Walter F. Rochelle, of Jackson; Puerperal Septicæmia, by Dr. James H. Preston, of Humboldt; The Treatment of Pneumonia, by Dr. Robert J. McFall, of Cumberland City; The Treatment of Rheumatism, by Dr. Charles W. Fleenor, of Holston Valley; Chronic Gastritis, by Dr. William C. Bilbro, of Murfreesboro; The Cause, the Nature, and the Treatment of Laryngitis in Singers, by Dr. Richmond McKinney, of Memphis; A Report of an Interesting Case of Eye Disease, by Dr. James L. Minor, of Memphis; Abdominal Pregnancy, with a Report of a Case, by Dr. S. B. Fowler, of Gainesboro; Reports of Cases of Hæmorrhoids, by Dr. John L. Jelks, of Memphis; Sudden Deafness with Aphasia of Eight Months' Duration, by Dr. John T. Herron, of Jackson; Typhoid Fever, by Dr. Joseph R. Puryear, of Wier; The Treatment of Urethral Stricture, by Dr. William F. Glenn, of Nashville; The Motor and Sensory Areas of the Brain and Spinal Cord, and their Physiological Functions, by Dr. David R. Neil, of Lewisburg; A Report of Cases of Appendicitis with Hematoma of the Ovary; and Suprapubic Lithotomy in a Child, by Dr. William D. Sumpter, of Nashville; and a Report of a Unique Case of Gunshot Wound of the Abdomen, by Dr. Rufus B. Fort, of Nashville.

Original Communications.

AN EXTRAORDINARY CASE OF
AORTIC ANEURYSM.*

By CARL BECK, M. D.,
NEW YORK.

THE patient, an architect, aged thirty-nine years, German by birth, single, gives the following family history: Father died suddenly, when sixty-five years of age; mother also died suddenly, when sixty. His only brother died of typhoid fever at twelve. There were no sisters.

The patient denies lues, and the examination verifies his statement. Gout and chronic nephritis, as well as any erotic excesses, are also to be excluded. He was always well until five years ago; then, after lifting an excessively heavy weight, he noticed a small protuberance on the left side of his neck; this grew constantly, invading at last the whole anterior surface of the neck and the upper portion of the chest. It is highly probable that the exertion in lifting caused an enormous increase in the circulatory pressure, followed by an over-extension and probably a laceration of the tunica intima and media. Shortly after this he was admitted to a hospital, where he was treated for torticollis, as he states, for five weeks. During that period slight dysphagia and hoarseness had been present. He recovered again so far as to regard himself well for an entire year. Then a "severe attack of malaria" induced him to seek hospital treatment again. After having improved considerably he left the hospital, and for the last eighteen months, he says, he has been under medical treatment occasionally. I am very much indebted to Dr. J. Glensmann, who examined and treated the patient more than a year ago, for informing me that at that time the tumor had not exceeded the size of a large apple, and that the hoarseness was considerable then. Two months ago the man began to suffer from slight dizziness, with constriction of the throat and chest. Slight dysphagia and hoarseness recurred.

On October 31, 1898, when he entered St. Mary's Hospital, I saw the patient for the first time. The tumor had reached an enormous size, extending over the sternum, the sternal portions of the clavicles, and the whole anterior surface of the neck, the diameter of the latter portion being seven inches and a half (see Fig. 1). The constant pressure of the tumor had caused complete atrophy of the adjoining osseous structures, so that no visible trace was left of the sternum or of the sternal portions of the clavicles.

The examination of the heart, both by percussion and auscultation, revealed hypertrophy of the left ventricle. The apex beat was felt in the sixth intercostal space, one inch laterally from the mamillary line. Above the jugulum and in the right parasternal line diastolic as well as a systolic murmur was noticed, the latter being more distinct at the systole. On placing the hand gently on the thorax, slight vibrations were felt.

The lungs were normal. No cough was present. Sometimes, especially after any muscular exertion, there was dyspnoea. The percussion was dull to the upper

pulse 78; the temperature oscillated between 98° and 98½° F. The pulse of the right radial artery was weaker than that of the left, and lagged behind it appreciably. There were no signs of arteriosclerosis. The voice was clear and its great resonance simply remarkable, and the previously existing hoarseness had undoubtedly been due to pressure paralysis of the recurrent nerve. The dysphagia, undoubtedly caused by the pressure upon the oesophagus, was very moderate on his admission.

The subjective disturbances of the patient were then insignificant. He had a fine appetite, and had attended to his business for the preceding four weeks.

144

The pulsation was unusually moderate and compatible with the large size and the hardness of the tumor, and its circumstance pointed to the presence of a benign neoplasia. It must, however, be noted that the tumor is formed by adenoma and the associated tumor is made of connective tissue, and a second possibility is that the tumor could displace a neighboring structure, such as the lumen of the peripheral portion of the ureter, and cause the pain. In these two fortunate cases, the diagnosis is not difficult, as well as the patient's response to treatment (Fig. 1, 2). The surprising explanation

* Case presented to the Section in General Surgery of the National Academy of Medicine, February 1, 1899.

tumor can be obtained by skiagraphy than by percussio. There can be no doubt that the Röntgen rays enable us to recognize aneurysms at their earliest stages, so that frequently a series of prophylactic measures can be taken which may counteract any further aneurysm formation. The therapeutics being under perfect control, it can be ascertained whether under treatment either improvement, arrest, or still further expansion may take place.

The patient has been subjected to Barwell's diet and to gelatin injections after the manner of Lancereaux for the last two months. The injections have been well borne, except on one occasion, when a slight rise of temperature followed and persisted for three days. During that period the patient's general condition was considerably affected. There can be no doubt that the tumor has decreased in size; the hoarseness has disappeared entirely, and the subjective condition of the

FIG. 3.

patient is much improved. It would really seem that the gelatin favors the formation of coagula, absorption taking place by the lymphatic vessels. If the patient improves further, I shall consider galvanopuncture.

As to the technique of the gelatin injections, it may be added that I used five grammes of white gelatin suspended in two hundred cubic centimetres of a sterile 7-to-1,000 chloride of sodium solution. This mixture, after being heated to 98° F., was injected into the connective tissue in the immediate vicinity of the tumor by means of a large Collin's aspiration apparatus at intervals of four days.

Ichthyol in Digestive Disturbances. *Furstenberg's* *Lehrbuch der inneren Medizin*, 1899, N. 1, p. 100. *Gazzetta degli ospedali e delle cliniche*, March 1899, p. 100. She has obtained excellent results from the use of ichthyol in the chronic form of digestive disturbance associated with constipation.

A REMARKABLE CASE OF TERTIARY SYPHILIS.

By ELLIOT JANSON, M. D.

ASTORIA, OREGON.

THE following case is of interest both from a pathological as well as a therapeutical standpoint. It illustrates the ravages of this dreaded disease in neglected cases, and also teaches us what can be done medicinally in an apparently hopeless case.

October 12, 1898, I was called to attend Mrs. K., who had been ailing for some time. On arriving at the house, I found the patient seated in bed, her face partly covered with a cloth, moaning and wringing her hands, as if in great mental and physical distress. On questioning the patient, I elicited the following history: "Age, twenty-seven; American born, but of Irish parentage. Mother died at an early age of consumption; father died as the result of an accident at the age of forty-seven. She had four brothers, all well."

Personal History.—Nine years ago she contracted syphilis from her first husband, after being married a little over a month. She had the typical initial lesion, which healed up readily on treatment. She maintains that at no time had she had any eruption, or mucous patches in her mouth or throat. For five months she kept up antisyphilitic treatment, the attending physician having informed her of the true nature of the disease. At the end of this time, feeling perfectly well, she disregarded the physician's instructions to come back in a few months for a continuation of the treatment.

She received no further treatment until a year and a half ago, when, suffering from an ulcerated sore throat, she deemed it advisable to consult a physician. Realizing the true nature of the disease, he put her on antisyphilitic treatment, which was continued for six months. After this she felt well for about four months, when trouble again began, but, on account of lack of funds, she failed to return for treatment. For the first time she noticed a pimple, surrounded by a red area, forming on the bridge of her nose, followed by a return of the sore throat. The pimple healed slowly for about a week, when the sore throat again returned, it was converted into a small ulcer, which did not heal. This spread slowly, becoming more and more ulcerated. She also had frequent attacks of mucous patches. Her condition remained about the same until about three weeks ago, when the ulcer on the throat again attained the size of a thumb nail. The ulcer then began to spread very rapidly, covering the greater portion

of the nose. In the course of a week the bridge of the nose caved in, the soft parts seeming to melt away, leaving only the tip of the nose intact. Throughout all this time there was very little discharge, but considerable odor was noticed. The throat caused very little inconvenience until a week ago, when swallowing became al-

pendent between them, part of the ethmoidal plate could be seen. On inspection of the floor of the nose, I found a large perforation, of the size of a quarter, involving the soft parts and the hard palate, through which the patient could protrude her tongue at will. On looking into the mouth I found the soft palate entirely destroyed, the

FIG. 1.

most impossible. Severe headache had been constant during the last three weeks, it keeping her awake the greater part of the night. Her appetite was very poor, and she mainly subsisted on liquid food.

Present Condition.—On removal of the cloth from her face the patient presented a pitiable sight. Where the original site of the nose had been, I found a large elliptical-shaped ulcer, which commenced at the junction of the nasal and frontal bones, spreading laterally close to the inner canthus of both eyes, extending downward, involving the cheeks within a quarter of an inch of the malar eminence. Of the nose there was nothing left but the tip, which, from lack of support, fell downward and forward, hanging over the upper lip. The bony framework of the nose was entirely gone; both the

FIG. 3.

posterior pillars of the fauces nearly gone, also extensive ulceration of the whole pharyngeal wall and vault. The accompanying photographs, Figs. 1 and 2, taken before treatment, will give the reader a fair idea of the condition of the patient. She was fairly well nourished, but extremely nervous, and suffering intensely from headache.

Treatment.—Although the case appeared almost hopeless, I gave her all the encouragement I could under the circumstances, and put her on the following treatment: Internally, a saturated solution of potassium iodide, commencing with fifteen drops and increasing two drops every dose, to be taken in milk three times a day. Locally, a twelve-per-cent. ointment of calomel was applied, while a spray of corrosive sublimate (1 to

FIG. 2.

nasal bone and the nasal processes of the superior maxilla were destroyed. Not a vestige of the cartilaginous septum or the vomer was to be found. The inferior and middle turbinated bones were destroyed; the superior turbinated were still intact, but red and swollen. Sus-

FIG. 4.

4,000) was ordered for the throat and interior of the face. Enough morphine to quiet the pains was allowed. In three days the headaches had subsided sufficiently for her to discontinue the morphine. The iodide of potassium was gradually increased until she was tak-

ing seventy-two drops three times a day, when the point of toleration was reached. I was, however, able to continue this dose until the healing was complete. The result of this treatment was nothing short of marvelous. In a few days the discharge diminished, and healthy granulations appeared, which very soon filled up the undermined edges.

On reaching the level of the surface, the cuticle assumed renewed activity, sending out prolongations which soon coalesced, gradually covering the ulcer with a healthy, soft integument. The tip of the nose was carefully adjusted and held in place. In a very short time it became adherent on one side to the margin of the ulcer, partly filling up the opening in the face, thus to a great extent obviating the disfigurement. At the end of five weeks I find the patient in perfect health and in good spirits, doing her own housework. The ulcer has healed completely, leaving an opening at the upper part of the nose, extending down the left side. Photographs 3 and 4, taken at this time, will convey to the reader an idea of her appearance better than words can tell. The throat and fauces are in a perfectly healthy condition, the ulcerated parts being covered by healthy mucous membrane. I kept the patient on full doses of the iodide for three weeks longer, when I gradually reduced the dose to thirty drops three times a day. I then put her on the inunction treatment with mercurial ointment (thirty-three per cent.), still continuing with small doses of the iodide. At the end of two months more I discharged the patient with instructions to come back in three months for another course of treatment.

REPORT OF A NECROPSY IN A CASE OF ACROMEGALY, WITH A CRITICAL REVIEW OF THE RECORDED PATHOLOGIC ANATOMY

By LOUIS J. MITCHELL, M.D.,

AND

E. R. LE COUNT, M.D.,

ASSISTANT PROFESSOR OF PATHOLOGY, RUSH MEDICAL COLLEGE, CHICAGO

PART I.

By Dr. MITCHELL AND Dr. LE COUNT.

INTRODUCTORY.—The clinical features of the case about to be reported have been fully described by Church and Hensert,* so it is only necessary to recall a few data.

The patient, A. K., was forty-one years of age when he first came under observation in 1893; was 162.5 centimetres in height, and weighed 81.1 kilogrammes. He had apparently been afflicted with the disease for many years, for we learn that while still a young lad, on going to buy a pair of gloves, his hands were found to be unusually large, needing a man's size. Some ten years before this examination he came to this country and began to attract attention on account of his large head and hideous aspect. When first seen, he was under treatment in the county hospital for syphilis, and left after a stay of some length. Nearly two years later, in January, 1895, he was taken sick, and, after staying in a lodging house for a week or so, started to walk to the hospital with a friend's assistance, but fell dead on the

corner of the hospital grounds. The necropsy, twenty-four hours' post mortem, showed death to be due to lobar pneumonia; the cranium and bones of the extremities on one side were dissected out and macerated.

Necropsy Report.—The brain appears normal except for an injection of the meningeal vessels. The hypophysis is very much softened, and removed only with considerable difficulty from the fossa, which is much enlarged. It consists of a semiliquid mass of grayish-red tissue, which does not seem to be greater in bulk than the normal hypophysis.

The thyroid weighs seventy grammes; the left lobe measures $6.8 \times 3.1 \times 2.5$ centimetres; the right, $7.5 \times 4.3 \times 2.5$ centimetres. On section it appears normal. No thymus gland or remains of thymus are found.

The left pleural cavity is empty and free from adhesions. The left contains a small amount of sanguinolent serum.

Lungs: The right lung weighs 560 grammes; it measures $25 \times 18.7 \times 10$ centimetres. There are many spots of black pigment in the pleura. The lung floats and crepitates throughout; the anterior and lower borders of the lower lobe are emphysematous; there are no changes about the apex. On section, a small nodular area is found in the lower external portion of the upper lobe which contains a cavity 1.5 centimetre in diameter, filled with grayish pus. The surrounding lung tissue is consolidated to a slight extent; the remainder of the lung shows no areas of consolidation, but appears engorged with blood. The left lung weighs 1,330 grammes; it measures $26.2 \times 23.6 \times 8.7$ centimetres. The pleura over the upper lobe is covered with a soft fibrinous exudate, easily removed. This lobe is massive and firm, and on section shows a gray, granular surface from which casts of the alveoli and small bronchioles are easily scraped; portions of this lobe sink at once when placed in water. A distinctly mucopurulent material escapes from the larger air-passages on pressure. The auricular part of the upper lobe, the anterior margin, and extreme apex consist of much-dilated air sacs, easily collapsed by pressure. The lower lobe contains but little air, much fluid, and some areas of consolidation in its centre.

The pericardial cavity contains a small amount of clear fluid; its surfaces are smooth and of an even color throughout.

Heart: Unopened it weighs 450 grammes. There is a thick deposit of fat over the base of the heart, measuring from five to seven millimetres in thickness. The mitral valve admits two finger tips; the tricuspid, five. The cavity of the left ventricle measures eight centimetres long; its wall, 2.8 centimetres; the cavity of the right ventricle, 8.7 centimetres; the wall, 6 to 9 millimetres. The left ventricle is empty; the right ventricle and auricle contain a small amount of "goose-fat" clots. The endocardium in the left ventricle shows a few yellowish thickenings just below the aortic valves for a distance of one to two centimetres. The cord tendons are shortened and the muscular bands thickened in the left ventricle, some of them extending over two centimetres in length. The mitral valve is slightly thickened at its free edge. The pulmonary and pulmonary valves show no changes. The coronary and auricular appendages appear normal. The aortic valve is closed. The aortic valve and coronary arteries at their points of contact and attachment to the ventricle are of a firm consistence throughout, and of a brown color, and shows on close examination a few small white thread-

* Medical Record, May 6, 1894.

like streaks which run parallel with the muscular fibres and appear located, as a rule, around the blood-vessels.

The coronary orifices are open. Both coronary arteries are very much dilated and tortuous. The right is found with its lumen empty to the apex of the heart. The left measures thirteen millimetres in diameter three

FIG. 1.—Section of hypophysis. $\times 75$.

centimetres from its opening into the aorta, and contains a few atheromatous plaques in its wall—most numerous near the aorta.

Aorta: Just above the valves are many scalelike plaques, completely calcified, which readily shell out, also other yellowish areas which show no signs of calcification. In the thoracic aorta many similar calcified plates are met with, as well as grayish and yellowish raised areas. Some of the areas of calcification measure a centimetre across.

The diaphragm extends upward to the fourth rib on the right side and to the fourth interspace on the left side.

The abdominal cavity contains only a slight amount of fluid. The peritoneum is smooth and shiny everywhere. There are no adhesions except a few about the gall bladder and hepatic flexure of the colon. The omentum covers the intestines only in part, reaching a point opposite the umbilicus.

The stomach weighs two hundred and eighty-five grammes. It measures $26.2 \times 11.2 \times 7.5$ centimetres. The pylorus admits one finger easily. The mucosa appears to be thickened, and is covered with considerable grayish-brown mucus. It is thrown into many folds, which generally conform to the rugae in direction; these folds are almost entirely obliterated by stretching.

In the intestines the solitary follicles and Peyer's patches are found enlarged and considerably bile-stained. Considerable mucus, exceedingly viscid, adheres to the mucous membrane of the small intestine. The mesenteric glands are considerably enlarged and contain pin-point ecchymoses. The appendix, short and thick (four centimetres long), lies on the right ilio-pectinal line.

Liver: The weight is 3,550 grammes. It measures $29.3 \times 29 \times 13.7 \times 11.8 \times 8.7$ centimetres. Externally, midway between the superior and inferior borders, it presents a groove extending transversely from the fis-

sure between the right and left lobes to the right border; this constriction marks off about one fifth of the right lobe. The fissure between the right and left lobes is much exaggerated, being about 6.2 centimetres in depth. The surface of the liver is irregularly nodular, the elevations measuring 0.5 to one centimetre in diameter. Between these elevations are bands of white connective tissue in the capsule. The surface of the cut section is rough; the islands of liver tissue which project as elevations measure from one to five millimetres across. In consistence it is firmer than normal; in color, a uniform grayish red. The gall bladder is empty and the bile passages are patent.

Spleen: The weight is 450 grammes, and it measures $18.7 \times 10 \times 5$ centimetres. The capsule is wrinkled and the pulp softer than normal; the Malpighian bodies are faintly visible; the connective tissue is not increased. A few small, whitish areas in the capsule occur, at which points the capsule is thickened.

The pancreas weighs 105 grammes, and measures $23.7 \times 3.7 \times 1.2$ centimetres. On section no changes from the normal are visible.

The adrenals appear normal; the left weighs 20 grammes, the right sixteen grammes. The left measures $7.5 \times 4.3 \times 1.2$ centimetres; the right measures $5 \times 4.3 \times 1.2$ centimetres.

Kidneys: The left weighs 300 grammes; it measures $15 \times 6.8 \times 5$ centimetres. Externally are many depressed areas, 0.5 to a centimetre in diameter and depressed below the surface one to two millimetres. There are also many small subcapsular cysts possessing clear contents, averaging one millimetre across. About thirty of these are found on one side of the kidney. On section the cortex and pyramids appear of the same shade of color, the cortical markings distinct, labyrinth wider than normal, the line between pyramid and cortex indistinct. The cortex measures 1 to 1.5 centimetre; the pyramid, 2 to 3 centimetres. There is an excess of fat in the pelvis, and the capsule is quite adherent. The right

FIG. 2.—Section from pancreas. $\times 75$.

kidney weighs 360 grammes and measures $15 \times 8.4 \times 3.7$ centimetres. It answers to the same description as the left kidney.

The other organs were negative.

Anatomical Diagnosis.—Lobar pneumonia, fibrinous pleuritis, cirrhosis of liver, softening of hypophysis, and enlargement of the viscera.

Microscopical Examination.—The hypophysis, as before stated, was so much softened that solid pieces could not be obtained, but a small amount of this semifluid tissue was collected and hardened in alcohol. Sections stained with hæmatoxylin and eosin show many fields where the tissue is not much torn; such fields are made up more or less of short rows of cells resembling tubules. In certain fields the row formation is more marked than in others; small capillaries run between the rows of cells. The cells forming these rows are more or less columnar, and certain single cells show this better than others; the arrangement in rows is more a dense linear accumulation of cells than an appearance due to the columnar or cubical character of the cells. These cells possess oval or circular nuclei which stain darkly—the nuclear membrane being well differentiated; many of the nuclei are large, many irregular in contour. Both nucleus and cell body vary in size considerably. The cell bodies are quite large; they stain well with eosin, as a rule, but occasional cells have a disposition to take the hæmatoxylin stain in place of the eosin in the cell bodies. Some large cells occur with the nucleus nearer one edge of the cell. The areas where tubule or row formation does not prevail seem to be made up of similar cells, but much scattered and disarranged. The connective tissue is very scanty and is confined to the region immediately around the blood-vessels. The blood-vessels show no changes; no earyocinetic figures are present. Sections of this hypophysis were submitted to Dr. Adolf Meyer, of Worcester, Massachusetts, who pronounced the condition to be one of hyperplasia.

Lung: The left upper lobe shows the microscopic features ordinarily seen in lobar pneumonia. The alveolar contents are markedly fibrinous, with considerable degeneration of cells—i. e., failure to stain. There is also

FIG. 3.—Section of thyroid gland.

considerable blood in the alveoli, and a marked pericardial and peribronchial deposit of coal pigment.

The abscess wall from the right lung shows a fibrinous wall beset with vessels; there are no eosinophilic tubules in the surrounding tissue. The lining possesses a few polymorphonuclear leucocytes.

Heart: The pericardial covering shows a slight increase in thickness of the under layers, with here and there larger bands of fibrous tissue extending into the myocardium. These bands are usually provided with vessels. The endocardium appears unchanged.

FIG. 4.—Front view of the hypophysis growth, Rathbun's case, actual size.

There is considerable pigment opposite the poles of the nuclei in the shape of small, golden-brown granules. Both segmentation and fragmentation of heart-muscle fibres occur, the fragmentation being the more marked. The nuclei of the muscle fibres exhibit various sizes ("giantism," "hyperchromatosis"). The arterioles show a slightly thickened tunica media; the connective tissue between the muscle fibres is but little increased. A few foci are seen where the muscle fibres have disappeared, and their places have been taken by a slightly granular grayish tissue in which are scattered spindle-shaped and oblong nuclei.

Stomach: The mucous membrane is very atrophic; the glands are fewer than normal and infiltrated with deeply staining round cells, many of which are fibrillated. There are accumulations of brown granules of pigment at the bottom. At certain points the round cells are accumulated in round foci internal to the muscularis mucosæ, which is thickened. The submucous coat is narrow and consists of a large amount of fibrous tissue devoid of nuclei. The tunica media of the vessels is thickened.

Small Intestine: The mucous membrane is very atrophic; the glands are very short; there is a marked increase in small round cells which stain darkly in the mucous coat. There are also many spindle-shaped cells, gathered around and between the glands. The muscularis mucosæ is very much thickened, and the connective tissue in the submucous coat is also increased in amount, and is hyaline in character. The vessels show thickening of the tunica media.

A mesenteric lymph gland is found to possess an increase in connective tissue; there is an increase in the number of blood vessels, as large as normal, which are filled with blood; a marked hyperplasia of the inner gland reticulum, and pigmentation with coal dust.

Liver: The lobular arrangement of the liver cells is much broken up by the connective tissue of the stroma.

The liver cells show more pigment here and there. There are very few tubules. The eosinophilic staining is uniformly good, except in a few areas of dilatation of the capillaries, as venous sinusoids.

The connective tissue is increased in amount in the shape of large, coarse bands, and there is a deposit of quite mature connective tissue. There are numerous vessels

with thin walls filled with blood in these bands. The intermediate-sized bands of connective tissue are more embryonal, and in these the vessels are more numerous. In addition to these there are minute bands of connective tissue made up mainly of rows of round cells. Increase in bile ducts is not so marked as is usually seen in atrophic cirrhosis.

FIG. 5.—Back view of the hypophysis growth, Rathmell's case, actual size.

Spleen: The Malpighian corpuscles are irregular, not well defined, usually smaller than normal, but otherwise negative. The spleen pulp cells are almost entirely made up of small round cells; nucleated red corpuscles are found in the sinuses; polymorphonuclear leucocytes are very infrequently seen. There are numerous accumulations of blood pigment. The blood-vessels all show great thickening, especially in the tunica media. There are no degenerative or necrotic processes observed. The con-

which is largely hyaline; in this are small arterioles with their middle walls thickened. The connective tissue about the larger ducts is very much increased in amount, and the lining cells are several layers thick. The ducts are irregular and tortuous; some desquamation of the cells occurs. The connective tissue about the acini appears heavier and more easily seen than is usually the case. There are numerous small foci of hæmorrhage and dilated veins filled with blood.

Adrenals: There is marked pigmentation with blood pigment. The engorged vessels in the medulla contain a marked excess of leucocytes. The nuclear staining is uniformly good. The trabecular leading into the gland from the capsule, and also the capsule itself, seem to be heavier than normal.

In the thyroid there is an increase of both interlobular and interacinous connective tissue, a great diminu-

FIG. 7.—View of skull (slightly tilted) from the inside, showing the enlarged sella turcica, also Wormian bones.

tion in size of the follicles, and thickenings in the tunica media of the blood-vessels.

Kidneys: The glomeruli show usually a slight capsular space; they are filled with blood; there is a marked increase in thickness of the walls of the capillary loops. There are numerous oblong nuclei in the glomerulus; many glomeruli are smaller than normal, in which case Bowman's capsule is usually thickened. There is a connective-tissue increase at the arterial pole of the glomerulus in the shape of short, spindle-shaped cells. The convoluted tubules show good nuclear staining; the protoplasm is very granular. The collecting tubes are negative. The blood vessels show a marked capillary engorgement both in the pyramids and cortex. There are similar changes in the small arterioles as were observed in other viscera. The connective tissue of the kidney is not increased. The subcapsular cysts show a lining of short cubical cells. There is a deposit of blood pigment in the pyramids.

FIG. 8.—View of skull from the outside.

nective tissue is slightly increased in the finer reticulum; the large bands are heavy and contain fewer nuclei than normal.

The pancreas exhibits a marked increase of stroma,

Cranium: The antero-posterior diameter is twenty centimetres; the bipiternal, fifteen centimetres; the greater part of the coronal suture is obliterated outside, and entirely so inside; the same holds good for the sagittal, but the lambdoid is open on both faces. The metopic suture is present for 2.5 centimetres at its lower end.

The ridges for muscular attachments are well marked. This is so much the case over the mastoid and suboccipital regions that the surface is studded with masses and nodules of bone from three to six millimetres in thickness, from which the occipital protuberance stands out as a large boss ten millimetres long. The external occipital crest is very well marked also, forming a sharp ridge. The styloid process is only twelve millimetres long.

The malar bones are enlarged and very prominent, causing a deep hollow below them. The suture between the malar and maxilla is obliterated on both sides.

The supraorbital ridges are enormous, as may be seen from the photograph. A piece was removed from the anterior wall of the frontal sinus, showing that the bosses are not due to the thickening of the plates of the skull, but to increase in the size of the sinuses.

The orbits were enlarged in both their transverse and vertical diameters. The sphenoidal and sphenomaxillary fissures were enlarged also, the latter being six millimetres wide. The external pterygoid plates are very rough and thick. The hamular process is large (twenty millimetres). The first and second molars are missing on both sides below, and the first and second on the left above.

The nasal septum is deviated to the right. The external auditory meatus is enlarged, but there are no exostoses.

The mandible is asymmetrical, the right ramus being two centimetres longer than the left. This is partly compensated for by the increased length of the left coronoid process. The condyles are three centimetres wide; the left coronoid process is unusually high (three centimetres), thus making the sigmoid notch on that side narrow and deep. The right coronoid process is but twenty-three millimetres high. The muscular ridges are well developed; there is a well-marked osteophyte, eight millimetres thick, at the angle of the jaw on the right side. The bone, as a whole, is very massive and thick, the body much inclined forward. The rami join the body at an obtuse angle, resembling that of the edentulous jaw of old age.

On the interior of the cranium there are numerous osteophytes over the base and one on the vault measuring 2.5 centimetres by 12 millimetres. There are two Wormian bones in the roof of the right orbit and four in the left. The superior border of the petrosa is unusually sharp on both sides. The sella turcica measures 4.5 × 2.5 × 2 centimetres; the floor is pitted by several large holes. On the right side the boundary between the sella and middle fossa of skull has quite disappeared. On the left it remains in part. The anterior clinoid process is unusually well marked; the dorsum sellae is very thin and parchmentlike. The bones of the skull are not thickened; indeed, over the temporal region they are unusually thin.

The clavicle is 15.5 centimetres long; the sternal end is prominent, and the articular surface for the thorax is increased in size. The muscular impressions are unusually well developed on this bone as elsewhere.

The scapula is 15.5 centimetres deep. The scapular index is 64.6. The supraspinous and subscapular fossae

are unusually well marked. The muscular impressions on vertebral border, and especially the axillary border, are large and rugose.

In the upper extremity, the humerus is 32.5 centimetres long, the ulna 23 centimetres, the radius 25 centimetres. The muscular impressions in the upper part of the humerus and ulna are again noticeably prominent. The lower end of the radius is very large; the carpal bones are unchanged. The metacarpal bones and phalanges are rough; the distal phalanges very large—widened, thickened, and rough.

In the lower extremity the femur is 12.5 centimetres long, thick, and clumsy looking; the impression for the gluteus maximus is well marked, almost forming a third trochanter; otherwise there is little change. No change is to be found in the tibia or fibula. The insertion of the tendo Achillis into the calcaneum is marked by an irregular mass of osseous tissue. The ungual phalanges, like those of the upper extremity, are thick, flat, and rough—studded with osteophytes.

There was no kyphosis.

(To be concluded.)

SOME OBSERVATIONS ON MALARIAL DISEASE IN THE PROVINCE OF SANTIAGO DE CUBA.*

By FREDERICK W. FABRICIUS,

ACTING ASSISTANT SURGEON, U. S. ARMY;
PATHOLOGIST AND BACTERIOLOGIST TO THE U. S. GENERAL HOSPITAL,
SANTIAGO DE CUBA.

THE most prominent of endemic diseases in this district is malarial fever. The statement has been made by a native physician of reputation that more people die from it yearly in this island than from all other diseases combined. No matter how mild the case, the disease in the tropics should always be regarded as of possible serious import and the case treated accordingly. It is a disease that often attacks the natives, but the newcomer from northern countries rarely escapes its influence. If not directly fatal, it always undermines the health, and debilitates and drains the system, thereby rendering it more susceptible to other infections and paving the way for organic diseases and chronic invalidism.

Malarial disease presents so many different forms that it frequently leads to fatal errors in diagnosis, by closely simulating grave organic and nervous lesions. I have seen it mistaken for acute Bright's disease, nephrolithiasis, spinal hæmorrhage, apoplexy, sunstroke, epilepsy, dysentery, beriberi, yellow fever, typhoid fever, etc., when a careful microscopical examination of blood specimens would reveal the true nature of the malady and point out a line of treatment with remedial measures of truly specific value. It can safely be asserted that a timely hypodermic or intravenous injection of quinine in solution has saved a good many lives. The

* Read before the chief surgeon of the Department of Santiago, Cuba, and transmitted from the office of the surgeon-general of the army.

combination of quinine and urea (quinine dihydrochloride carbamide, containing sixty-nine per cent. of pure anhydrous quinine) has given great satisfaction, and the writer has used it since 1893 in hospital and private practice in a large number of cases, without producing a single abscess. It dissolves in an equal quantity of distilled water. The solution being alkaline, the quinine is not precipitated by coming in contact with the alkaline juices of the body, and is therefore readily absorbed. Thirty and even forty-five grains in twenty-four hours have been given in grave cases of malarial hæmaturia with good result, without any apparent harmful effect from the urea existing in combination with the salt. Native physicians in this district seem to regard all hæmaturia as of malarial origin, and exhibit rather large doses of quinine. The mortality in these cases is said to be high, and well-informed physicians from the southern United States, where hæmaturia also is frequent, allege that quinine only adds to the renal inflammation, and abstain from its use entirely, with a seemingly lower mortality rate. Clinical experience and microscopical investigations have taught me that quinine in large doses does harm when the plasmodium is absent from the blood, but is decidedly beneficial when the plasmodium is present; in other words, when the hæmaturia is really of malarial origin.

The malarial organism finds a most favorable soil in certain regions of this district, where the altitude is low and hygroscopic influence marked. The city of Santiago is located on a level stretch of ground surrounding the extreme upper end of the bay, with a gentle slope upward toward the east, terminating in a plain with hilly elevations, distantly surrounded by rather high mountains. The hills, of such types as San Juan, El Poso, El Caney, etc., are numerous, with a gentle slope, well separated from each other, so that the intervening land is nothing more than an irregular basin, more or less densely covered with underbrush and a rich tropical flora. The geological conditions of these lowlands may, in a general way, be described as alluvial soil, composed of layers of sand with an abundant vegetable growth, and an impermeable subsoil of sand, clay, and sedimentary rocks, especially abundant in and about the town of El Caney. A great number of ravines and old river beds—converted into torrents during the rainy season—suggest extensive subterranean water courses and an abundance of subsoil water. Marshes are numerous, but not very extensive; and, while some are called into existence by the rainy season, others are permanent. The drainage from these marshes is either very defective or totally absent, and we find the soil either water-logged or partially submerged; in some places this condition is concealed by very dense underbrush and abundant vegetation, preventing free circulation of air and favoring vegetable decay. A good part of this land, under cultivation prior to the insurrection, was completely abandoned several years ago, and is now a dangerous

focus for malaria. This deplorable condition is very striking in and about the village of El Caney, which is regarded by the natives as a hotbed of malarial disease. An old resident told me that hardly any one now living in the town was free from fever.

A curious conformation is noticed in connection with malaria in younger children: the abdomen appears greatly distended and bulges forward as in advanced ascites or obesity. The abdominal veins are much enlarged. On palpation, the abdominal wall is found to be of normal thickness, but tense and elastic; the spleen is enlarged, sometimes to an enormous extent; in one boy of twelve years the spleen extended from the seventh intercostal space to the anterior superior spinous process of the ilium, and from the quadratus lumborum an inch to the right of the umbilicus; the borders were thick and rounded, and imparted to the touch a sense of firm resistance, like a solid piece of rubber. The anterior surface was rough, but not adherent. This child, though up and about like all these children, was markedly anæmic, and very dull and indifferent. The unusual abdominal distention is caused by considerable tympanites; this may partly result from general malnutrition or intestinal parasites—which are very frequent among the poorer children—but to a great extent is due to a passive hyperæmia of the abdominal viscera, notably the spleen and liver.

The period of time when malarial fever first appeared in this part of the island can not be ascertained, owing to the lack of medical statistics. It is certain, however, that it has existed for a long time under the name of "calentura," a term which is nowadays applied to any form of fever by the natives. At the present time malarial disease is very prevalent, not a very surprising fact if we consider the following conditions *in toto*:

1. A tropical climate with abrupt temperature changes.
2. An unhealthy soil, with inadequate drainage, and a constantly changing level of ground water, with areas of water-logged land and marshes.
3. Profuse tropical vegetation, with decaying organic matter furnishing a most favorable breeding place for suctorial insects.
4. Areas of land, previously cultivated, lying waste for several years.
5. Hygrometric variation; a prolonged rainy season flushing old river beds which are entirely dry during the rest of the year.

These associate conditions are recognized as potent factors in the biology of malarial disease, not only by stimulating plasmodial propagation, but also by their injurious influences on humanity. The strongest predisposing element in the development of any disease is a lowering of vital resistance, be this through unsanitary surroundings, intemperance, or undue exposure. As soon as the individual standard of health is lowered through any or all of these agencies the morbid influ-

ences find a favorable soil and flourish, and this applies especially to malarial disease. There is no doubt that a good many people, even though directly exposed to the malarial poison, escape infection. This can only be explained on the ground of a perfect physiological mechanism; let this individual, however, undergo severe mental strain or prolonged and unusual physical exercise, or become intemperate, then the perfect physiological machinery breaks down, and the system can no longer withstand the invasion of the poison even on moderate exposure. A marked illustration is offered by the late campaign. Strong, healthy men from all parts of the United States were sent to the island; some, failing to adapt themselves to tropical influences, continued to pursue their northern habits, and, not being used to the high temperature and marked degree of humidity during the day, threw off all superfluous clothing and rashly exposed themselves to the chilling night air; others, in trenches, were forced by the existing circumstances to endure all sorts of hardships, constantly exposed to malarial poison. A number of these men succumbed to the disease; a great many have come out alive, but are nothing more than physical wrecks. Excesses and intemperance of any kind are powerful predisposing factors in the tropics, particularly at the end of the rainy season, when malarial prevalence reaches its maximum.

The exciting cause of malarial fever was discovered by Laveran in 1880, and first studied in America by Sternberg in March, 1886, at the Johns Hopkins University. The plasmodium is now classified as a hematozoon, belonging to the sporozoa, which, as R. Pfeiffer has recently demonstrated, closely resemble the coccidia. Notwithstanding the constant association of the plasmodium with most malarias, some observers still look upon the *Bacillus malarie*, discovered by Tommasi Crudeli in 1879, as the *causa malarie*. Sternberg, in 1880, by a series of exhaustive experiments, conducted in his laboratory in New Orleans, proved conclusively that this bacillus did not exert any etiological influence on malarial disease. This view is now generally accepted over the western hemisphere.

From the foregoing it will at once be assumed that the parasites met with in malarial disease are very numerous in this part of the country; the malignant varieties greatly exceed the benign, the latter being generally represented by double or multiple infections.

The benign forms encountered so far have been in the foreign element mostly, in soldiers and civilians from North America. This leads me to suspect that the malarial infections antedate their arrival here on the island, and this in a good many instances is supported by the previous history of the patient. In a few specimens the quartan parasites were discovered, in the rest the tertian type, mostly of the double variety. In isolated cases a multiple tertian infection was noticed; one such case was under my care at the Josiah S. Sisson General Hospital, Fort Monroe, Virginia. The patient

was sent from Ponce, Puerto Rico, to the hospital for treatment. The temperature chart which accompanied him showed a distinctly remittent fever curve. Examination of the blood revealed the benign tertian parasites in all stages of development. Under moderate doses of quinine the remittent fever gradually resolved itself into an intermittent quotidian, and later into tertian paroxysms, which yielded eventually to quinine. It is not uncommon in the North to see a quotidian fever, at times even without specific medication, change to the tertian type.

In the tropics, however, it more frequently takes on the malignant form. In the active element, although a number of cases were examined, benign parasites did not come under the writer's observation.

The malignant type seems to be the endemic form of malarial parasite in this region; the pigmented and unpigmented malignant quotidian parasites are notably abundant, in the native as well as in the foreign element. They appear as minute amœboid bodies, with constant tendency to ring formation; after a few seconds of rest they would diffuse themselves through the cell substance, almost disappearing from view. They seem to obtain nutrition in this manner in their early phases, precipitating fine black pigment in the one, but not in the other variety. The two types have not been found associated. The unpigmented forms were very frequently found in dark bronzed red blood-cells. The number of these parasites in the circulation must be enormous; in one field as many as eighteen hyaline bodies were found (one-twelfth oil-immersion, Bausch and Lomb). The crescents in both these varieties seem to be nearly alike; they are smaller but thicker than those found in the tertian malignant form; the central cluster of pigment is rather fine and gradually arranges itself in the form of a fine network, the crescentic body contracting—i. e., becoming shorter and rounder. Their resisting power must be very marked, for one was observed undergoing gradual changes for a space of six hours, assuming a finally rounded form, the central pigment resembling a delicate coil of black thread.

In the malignant tertian variety the parasites were found to be much larger than, in the malignant quotidian, ranging in size from a third to two thirds of that of a red blood-cell, with very fine, active, black pigment. The earlier stages are amœboid, but these movements gradually cease. The crescentic form is larger than in the malignant quotidian, and the central pigment coarser and more active; they are frequently found adherent to the red blood cell.

Mixed types were also met with; in one case only crescents were found, the patient being under observation for two weeks; he was very anæmic, had a greatly enlarged spleen, but was practically free from fever. In three cases of malarial hæmaturia, or tertian hæmaturia, a few hyaline unpigmented bodies were found, as well as fully formed pigmented parasites, which were

bling, but larger than, the malignant quotidian, with very fine yellowish-brown pigment; only one case presented crescents. The light color of the pigment is probably due to deficiency or marked diminution of the hæmoglobin.

In three cases the writer has met with a small, rod-shaped body, of a dark bronze color, of about half the length of the diameter of a normal red blood-cell, and a sixth of its length in thickness; the ends were somewhat thick and rounded. The organisms were not numerous in a specimen but very motile, rapidly passing across the field by a peculiar swinging motion of the posterior half; there was no amœboid movement; in its centre a highly refractive spot was seen, closely resembling a spore. The organism attacked a number of red cells in its course, apparently endeavoring to enter one; at times it would lie in close apposition to a cell. While under observation it gradually increased in thickness, especially at the ends. The movements became slower and finally ceased, and the bright refractive spot was seen to escape from it, dancing about between the adjacent cells, where it seemed to penetrate one and become lodged. The organism itself again became motile, the difference in thickness between the extremities and the centre becoming more marked, till finally a constriction separated the anterior from the posterior segment. In the latter another bright spot was visible. The organism divided into two parts at the constricted point. The posterior segment, with its spore, becoming round, entered a near-by red blood-cell, where it remained without any further change; the anterior segment was lost sight of. In one case this organism was found associated with small tertian parasites; in the other, with two very fine hyaline unpigmented bodies, resembling the malignant quotidian. In all these cases a large number of highly refractive spots, identical in appearance with the discharged spores, were found, both free in the plasma and inclosed in the red cells. Owing to the limited number of cases studied so far, no deduction will be made as to the probable pathological significance of these organisms; they will be reported on at a later date.

It is possible that the various clinical types of malarious fever are produced by one form of plasmodium, and that the varieties we observe are the result of alterations the parasite undergoes in the system, influenced possibly by climate and the patient's vital resisting powers—i. e., by the condition of red blood-cells, leucocytes, and nervous force. That these factors exert a great influence can not be questioned. We know that through some agency plasmodia are allowed to lie dormant in the system for a year or more without materially influencing the patient's condition, but when the system is depressed by a sudden change of climate or diseased processes the soil for microbic development is rendered favorable and the parasites multiply. We further know that some individuals recover from mild malaria (plasmodia present in the blood) without the use

of quinine, some with very little quinine, while others recover only under very large doses. If we could grant the possible existence of a malarial antitoxine the problem could be easily solved; but, if we admit that, would this not force us into admitting immunity as the direct result of antitoxine formation, as is the case, for instance, in yellow fever? Clinical experience does not bear out this statement; on the contrary, one malarial attack distinctly predisposes toward another. Residents in malarious districts—born and bred there—are by no means exempt from malaria; they are not immune; their system has adapted itself to tropical influences and surroundings; they are, moreover, fully acquainted with the dangers of the tropics, and avoid as much as possible violent exercise, exposure to direct heat of the sun, and drenching rains. They realize the importance of changing their damp clothing before the sun sets, and are not given to excesses of any kind. For these reasons they are less liable to malarial disease than non-residents, but when they are attacked by it the disease does not tend to pursue a mild course; this is especially true in regard to the lower classes, with whom fatal malignant types are common. These facts in themselves directly oppose the theory of malarial immunity; it appears to be more a question of vital resistance and physical tolerance than of antitoxine formation. The plasmodia within the human organism appear to be possessed of a remarkable affinity for the red blood-cells, owing probably to the amount of free oxygen they contain, which latter is an essential factor in the developmental process of the parasite. They seem to derive the necessary nutritive elements from the albuminoid substance—the globulin—changing the hæmoglobin as they mature into melanin, which is deposited in the form of fine or coarse granules. It is possible that this results from the abstraction of oxygen and a gradual disappearance of the globulin. Certain amounts of waste products—excrementitious matters—are formed which are toxic to the human organism. When sporulation takes place, and the parasite-containing blood-cells rupture, the spherules are suddenly thrown into the plasma, giving rise to malarious manifestations. What is this due to? To an impression made by the presence of the foreign bodies circulating through the basal ganglia and pontobulbar nuclei? To rapid invasion of new red blood-cells by the hyaline bodies? To a setting free of the excreta—toxines—of the sporulating group, profoundly shocking the sympathetic nervous system? It is possible that the explosive phenomena observed in malarial paroxysms are caused by a combined action of these three agencies.

What becomes of the immense number of spherules set free at each sporulation? In some cases, probably, nearly all enter red blood-cells, and bring about a fatal issue by destroying an immense number of oxygen-carrying cells. In most instances, however, only a limited number of organisms pass into red blood-cells, starting

on a new cycle of development, possibly under altered circumstances; the majority of the free bodies, following sporulation, probably perish in the plasma from want of oxygen or are killed through phagocytosis or other influences (cells of liver, spleen, and lymphatic glands). We are aware that certain plasmodial types require a certain amount of time to complete their cycle of development; we also are aware of the fact that in most instances of benign type the attacks anticipate—that is, the plasmodia reach the sporulating stage an hour or two sooner than in the preceding paroxysms—which means that parasites either find the soil more favorable or else have increased in virulence. If an antitoxine were produced by the plasmodia, as some suggest, would not this in itself stamp malarial fever as a self-limited disease? Would not these parasites, by constant multiplication, produce so much antitoxine as to finally overpower them? If the antitoxine theory were maintained, would it not mean immunity, or at least partial protection against further attacks, instead of rendering the system all the more susceptible to plasmodial influence? If an antitoxine does exist, it is produced outside of the human body and certainly not within.

A careful study of the clinical forms of malarial fever combined with microscopical and post-mortem observations has demonstrated the fact that the plasmodia exhibit a marked preference for rich capillary plexuses, where circulatory pressure is at its minimum, the flow of blood constant, and metabolic changes—tissue osmosis—very active, with an abundance of red blood-cells and high temperature. We find plasmodial nests in the plexuses of the spleen, liver, kidneys, lungs, intestines, brain, and spinal cord, giving rise to a multiplicity of symptoms—from a moderate neuralgia to fatal coma—with explosive phenomena resulting from the concentration of the malarial poison.

The existence of the parasite in its primordial state—*i. e., extra corpore hominis*—has not been demonstrated as yet, and is still a matter of conjecture. That the parasite can flourish outside the human body has been demonstrated by exclusion only, and how it gains entrance into the system is still a theoretical point. One person can not contract malarial disease by coming in contact with an individual suffering from it, which would lead us to suppose that the parasites are not excreted, but destroyed in the system. We do not know how malaria is propagated. It is assumed that it might be spread by drinking contaminated water; this, however, is hardly a source of danger, as the acid in the gastric juice would destroy the plasmodia. It is far more likely that access is gained into the system by inhaling infected dust. It has been demonstrated experimentally that an injection of fresh malarial blood, containing plasmodia in active state, into the vein of a person not suffering from the disease is followed sooner or later by an outburst of malarial disease. The weight of this evidence would tend to prove that the infection

is dependent on a direct circulatory inoculation, probably by suctorial insects, of which the mosquito is a type; their almost constant presence in the vicinity of swamps and malarious regions is certainly in favor of this theory. Sternberg suggests that the plasmodium, like other ameboid protozoa, may find its normal habitat external to the bodies of its animal hosts, upon the stems and leaves of water plants rather than in the water itself, for when marsh vegetation is submerged by high water malarial fever does not prevail in the vicinity of such swamps. This applies directly to this district, where malaria is less frequent after the rainy season has become well established, and the water-logged areas with their abundant vegetable growth are covered with water; the danger is greater when the water level sinks, partly exposing the soil. There are at least three swamps known to be malariously infected in this vicinity; they are of rather small size, with the centre partly submerged, while the periphery is water-logged and profusely covered with vegetation.

THE PRACTICAL APPLICATION OF THE SKIASCOPE.*

By J. W. SHERER, M. D.,

SECRETARY OF THE MIDLAND OPHTHALMOLOGICAL SOCIETY, KANSAS CITY, MO.

I AGREE with Dr. Edward Jackson, of Philadelphia, that skiascopy affords the most accurate means of refracting the eye. In order to yield exact results, however, the skiascope, like other instruments of precision, must be in competent hands, and I need scarcely add that a great deal of practice and training are necessary to give the requisite expertness.

The skiascope is capable of revealing very exactly the total refraction of the eye in every meridian, and especially of the central visual area of the cornea. Withal it supplies valuable data of other conditions, as irregular astigmatism, keratoconus, positive and negative spherical aberration, and if any residual accommodation remains to embarrass the refractionist it will be revealed. It yields such a clear conception of irregular astigmatism as can be secured by no other means.

The skiascopic examination, as originally made by Bowman, was done with the ophthalmoscopic mirror. He merely observed that conical cornea and irregular astigmatism were shown by it, and that regular astigmatism gave a linear shadow.

In 1872, John Cooper, of London, submitted some rudimentary observations, and two or three years later the first real progress was made by Cugnet, of Lille, who recognized the superiority of the plane mirror and its power in diagnosing all forms of ametropia.

Menzin and Parent now lecture its study in Paris,

* Read before the Midland Ophthalmological Society, Kansas City, Mo., February 13, 1899.

and Charnley, Lytton, and Forbes in London. In 1882, 1883, and 1884 Chibret, Story, and Priestley Smith developed the use of the plane mirror. Edward Jackson, who has probably done more than any one else to thoroughly establish skiascopy on a sound foundation, both scientifically and practically, in 1885 published an excellent monograph, which showed a perfect mastery of every detail of the test. Since then Dr. Jackson has been a main contributor to the literature of the subject, and author of one of the best text-books upon it.

For practical utility the text-book of Dr. James Thorington, of Philadelphia, is probably the best now extant. This is one subject in ophthalmology in which the names of Helmholtz and von Graefe do not appear.

As to the practical application of the test. I find a very general dissatisfaction among oculists at large over its employment. Inaccuracy is the principal fault charged, and inability to rely on its measurements of the refraction is also complained of. This I believe is almost entirely the fault of the observer. There is such a multiplicity of reflexes, such an entanglement of shadows, when the point of reversal is reached, such a nicety of judgment to be exercised in selecting the area to be measured, while ignoring the movement of the shadow in other areas, and such a vast diversity among eyes as to the amount of spherical aberration present, that it really takes much trained skill to make reliable data of the refraction.

Primarily, the room must be absolutely dark. Ignoring this dictum is a prolific source of disappointment. The best original source of light is an Argand gas burner mounted on a suitable bracket, and covered by an asbestos chimney, well blacked, and with but one orifice seven millimetres in diameter. The orifice should oppose the brightest part of the flame. The bracket should have an easy swing of rather a wide sweep to enable the observer to operate at different distances and keep the light near or remote from the mirror at will.

For exact measurements the mirror should be seven millimetres only in diameter with a sight hole of two millimetres and a half. The orifice needs to be well blacked, and a mirror with the mercury scraped off the back and not perforated is the best. A very small mirror is necessary, because it is only the rays of light in the centre of the illuminated area on the face which give the correct refraction. When the margin of the round disc of light which the mirror throws on the face is used, there is an angular deviation of the rays of light which prevents the most exact results.

The eye not under observation should be covered, and if the patient is requested to look at the surgeon's forehead just above the little mirror, the eye will be held about right to give the refraction of the visual axis, and still the patient will not be pained by gazing directly at the bright light.

Cycloplegia must be absolutely complete. The accommodation and refraction of the observer's eye are

matters of indifference. The eye of the patient, of the surgeon, and the light must all be on the same plane.

The lenses placed before the patient's eye should be clean and stand exactly at right angles to the visual axis. The pupil should occupy the centre of the lens. Plano-convex and plano-concave lenses should be used with the plane surface turned toward the surgeon. This rule applies to lenses up to about 4 D.

There are two movements to be given the mirror, the quick and the slow. The former is necessary when determining the character of the error of refraction and when the amount of uncorrected error present is large. When the error is nearly corrected, the last fine measurements are being taken and the reversal point is very near, a very slow movement of the mirror is necessary on account of the very swift motion of the shadow. A meterstick with a graduated scale of focal lengths in dioptries is extremely useful.

I do not wish to take up the optical principles of refraction with the shadow further than to say that the reversal point, which is the objective point of the surgeon, is the point where the rays emerging from the illuminated eye are brought to a focus. Within this point the visible image of the fundus is erect and the shadow moves with the mirror; beyond it the image is inverted or aerial and the shadow moves against the mirror.

The space is considerable between the point where a clear erect image and the point where a clear inverted image is secured, and within this space the image is blurred and practically indistinguishable. On the contrary, the point where reversal in the movement of the shadow is from erect to inverted is clean cut and sharp, it being hard to find the place where no movement either way occurs, but as the reversal point is approached the central illuminated area under observation is seen to grow smaller, brighter, and the movement swifter.

When the observer is remote from the reversal point the shadow moves very slowly; when near it the movement is very swift. Hence when working near the reversal point, I repeat, the mirror should be moved with extreme slowness.

Another most important point is in regard to the central shadow in contradistinction to the peripheral shadow. In a simple case of hypermetropia or myopia, at a distance from the reversal point, a large illuminated central area is seen surrounded by a dark ring. As the reversal point is approached the central area grows smaller, the dark ring contracts toward the centre, and a second ring appears around the first. This is bright and has a movement in a sense contrary to the central spot. This arises from the spheric aberration due to the difference in curvature of the centre and periphery of the cornea and lens.

The alert diagnostician will not allow this to deceive him when making the last fine measurements with a very small central shadow of very swift movement and a

very large peripheral shadow with a contrary movement almost swallowing up the former.

Varying the distance at which the mirror is held is a valuable aid. Thus, in a case of simple hypermetropia a lens may be placed before the eye sufficiently strong to bring the reversal point to within a few feet of the eye, and then by testing at different distances the erect and inverted movements will be found, and finally the exact point of reversal. This can then be measured with the meter-stick and the exact lens ascertained which is necessary to carry the reversal point to one metre. Thus, if the hypermetropia equals 3 D. and a 5 D. lens is put up, the reversal point will be found accurately at fifty centimetres, a little within which an erect movement and beyond which an inverted movement will be found. Deducting 1 D. will put the reversal point back to one metre, and deducting still another 1 D. for that distance the error will be known to be 3 D. of hypermetropia.

In myopia, the reversal point being naturally near the eye, no lens will be required to make the first estimate unless it be very high. When the reversal point has been brought to 1 metre 1 D. must be added to make the still convergent rays parallel and thus adjust the vision for distance.

The skiascopic finding which gives the best satisfaction for reading is one which gives a very slight erect movement, and which stops just short of entire neutralization of all movement, much more of complete reversal.

In astigmatism the round central spot of simple hypermetropia or myopia is converted into an oval, or if the astigmatism is high enough is stretched out into a long band, broader or narrower according as the observer is near or far from the reversal point of the opposite meridian.

The shape of the central illuminated area also depends upon the relation of the observing eye to the reversal points of the two principal meridians. Thus, if the observer is equidistant between the two points the area is circular, but in one direction moves with, in the other against, the mirror. On the other hand, if the observing eye is closer to that reversal point which is farther from the patient—i. e., the reversal point of the more hypermetropic or less myopic meridian, the band will, in hypermetropia, occupy the meridian of less error and marks the angle for the correcting cylinder.

In myopia, however, the band will now occupy the meridian of greater error, at a right angle to which the cylinder should be placed. In either hypermetropia or myopia the movement will be erect or inverted, according as the mirror is within or beyond the reversal point of the meridian inspected.

When the observing eye is closer to the proximal reversal point the same phenomena are observed, but *vice versa* to the foregoing as to the direction of the band and its indication for the cylinder.

In low astigmatism the indication for the axis of

the cylinder may be read wrongly owing to the fact that the edge of the illuminated area cuts the pupil at different angles according to the direction in which the mirror is turned. The straightest, longest edge is to be sought for and constitutes the desired indication.

In higher astigmatism there is no trouble of this kind; but another difficulty arises, since whether the light is made to travel obliquely or at right angles to the band, still the shadow seems to move perpendicularly to the band. If the mirror is moved in the long axis of the band no satisfactory movement can be seen, and hence observation is practically limited to the one meridian opposite to that occupied by the band. This difficulty is to be obviated by placing a suitable cylinder in the axis of the band.

The reversal point for each principal meridian is to be determined separately. If the astigmatism is low this can be done with spheres alone. The refraction of each meridian being noted, the requisite sphere and cylinder can be calculated. If the astigmatism is high a cylinder is needed to at least partly correct the astigmatism so that the movement of the shadow can be seen in each meridian.

Normally, and unless the error is over corrected, the band of light marks the meridian of lesser error—i. e., the meridian of greater curvature in hypermetropia and of lesser curvature in myopia and is the axis for the cylinder. A few trials enable one to always bring it to a maximum of intensity by putting up a lens which approximately corrects the meridian of lesser error and pushing the light away from the mirror.

The presence of astigmatism may also be recognized by a difference in the rate of movement in the two meridians. If the observer is within the proximal reversal point an erect movement will be seen in both meridians, but the rate of speed will be different in each. With considerable astigmatism the observer may happen to be located between the two reversal points, in which case, of course, he will see erect movement in the meridian of greater error in hypermetropia, and of lesser error in myopia, and *vice versa* as to inverted movement in the opposite meridians.

Having located and measured both proximal and distal reversal points, they should then both be brought to one metre and the central area should then be round, move with equal speed, and on trying a little nearer and a little farther away both should be found to reverse at just the same time. Then by deducting 1 D. for hypermetropia and adding 1 D. for myopia the trial case reading test may be proceeded with.

The skiascopic examination is completed in a few minutes, and saves much time and labor at the trial case, which is by no means overvalued by the skiascope, but remains the ultimate *arbiters* of error. Even when the operator is not fortunate enough to get the exact refraction with the skiascope, he is still greatly aided by it by the accurate conception of the refraction it

gives him. This is particularly true in compound and mixed astigmatism. In all forms of errors in children, malingers, and irresponsible persons it is invaluable.

I occasionally get the best results and a trifle more than $\frac{1}{2}$ vision with the skiascopic test, and rarely have to change more than a small fraction of a dioptre from the sphere to the cylinder, or *vice versa*, in order to get the best reading test. The scissors movement, which is frequently seen and which is so perplexing, is commonly attributed to tilting of the lens, such as sometimes results from reading lying down. It is caused by one part of the pupil giving an erect, and the other side an inverted, movement.

The dark, shadowy band between the two is the reversal point for the area which it occupies. By varying the distance of the mirror and trying different lenses this area may be brought to the central visual area and the reversal point to one metre. This, then, is the right correction, the necessary allowance being made for distance.

The lens selected should largely neutralize the opposing to-and-fro movement which, on account of opening and shutting like scissors blades, has given the name to the condition. As to irregular astigmatism, I will only say that it is instantly recognizable with the skiascope by the heterogeneous jumbling of the shadows. Of course, it is as incorrigible by one means as another, still, the skiascope is very useful in showing the true status of affairs.

The peculiar appearance of the pupil in keratoconus when inspected with the mirror, originally led to the discovery of the shadow test, which was early suggested for its diagnosis only. This consists of a triangular area of light with its apex occupying the centre of the pupil and its base to one side, which is seen when the mirror is rotated laterally. Turning the mirror causes the cone of light to wheel round the centre to the side to which the mirror is turned.

The optical condition amounts practically to one of high myopia with much negative aberration—i. e., there is lower myopia at the periphery of the pupil than at the centre. Consequently, the shadow moves against the mirror throughout the pupil; but, the reversal point for the periphery being much nearer the observer's eye than the reversal point for the centre, the shadow at the periphery moves much more rapidly and seems to literally run around the centre when the mirror is rotated.

A case of keratoconus should never be abandoned until it has been measured with the skiascope, which, if the lesion is low, may enable the oculist to correct it when all other means fail.

Expert kiascopists habitually take the refraction to within ± 2 D., and I have cognizance of clinics where one skiascopist, a matter of the shadow test, has been able to do the work which formerly occupied several men at the trial case.

If those of my colleagues who have found the skiascope unsatisfactory and unreliable will try it with the suggestions I have made, I am confident they will not be disappointed, but will concede its real value.

AN ARCUS SENILIS TATTOOED.

By W. L. BULLARD, M. D.,

COLUMBUS, GA.

Two narrow, opaque crescents, from three to five millimetres wide, an upper and a lower, situated close to the margin of the cornea, constitute a pathological condition named (wrongly) arcus senilis. In its incipency the marginal ring is not complete, but later becomes so by an absolute coalescence of the two crescents. The color varies, according to its stage of development, from a milky white to that of chalky whiteness in advanced cases. As its name implies, it has been commonly supposed to belong to old age; but this certainly seems to me to be a mistake, as it is not infrequently seen in young subjects under thirty years of age, and it is said to have been seen occasionally in children. I am also slow to believe it to be an indication or sequela of degenerative changes in the heart and arteries, inasmuch as I have seen it in patients whose age numbered as many years as eighty, and whose hearts had no degenerative changes; I have also seen patients with atheromatous degeneration whose eyes showed no arcus senilis. I have frequently seen it in cases of senile cataract, in the extraction of which by the corneal incision, which passes through the arcus senilis, heals as readily and with just as good results as in cases in which nothing of the kind exists. While I have never known it to interfere with vision, yet occasionally I am consulted regarding the abnormality, and in such cases advise non-interference, assuring the patients that it will never produce blindness, and that they need not worry about it. Sometimes, however, patients are not content with such advice, stating that, while it is not painful, and vision may never be affected, yet they feel it is an abnormality and an "eyesore" to them, and they request its removal in some way. I remember that some twelve years ago a schoolmistress, about thirty years of age, consulted me in regard to a perfectly developed arcus senilis in each eye. (I do not remember having ever noticed it in one eye only), and I gave her the usual advice—that is, non-interference; but this did not satisfy her, and she again called and pleaded for removal. I told her that with India ink I might be able to tattoo the "eyesore" black, the natural color of her eye, and in this way improve the eye from a cosmetic point of view, so to speak. I also told her that I had never operated on one in this way, yet, if its presence worried her to the extent alleged by her, and she was willing to have the operation repeated every few years (India

ink tattooed into the cornea is absorbed after a time), that I would operate on her eyes. She most willingly consented, and after three *séances*, a few days intervening between each, both arcus were tattooed under cocaine anaesthesia. The reaction was not at all severe, and the result proved to be perfectly satisfactory, and continued so for three years, after which time I lost sight of her. When physicians are anxiously consulted regarding an arcus, as a rule, the patient will be found to be under forty years of age, hence it may be suspected the worry is caused more on account of looks than from any discomfort or defect of vision produced thereby.

1408 THIRD AVENUE, COLUMBUS, GA.

Therapeutical Notes.

Bromol.—Bromol is described in the *Riforma medica* for March 16th as a yellow antiseptic powder useful in the treatment of ulcers and wounds. The following formulæ are given:

R Bromol 60 grains;
Sterilized vaseline 450 "

For an ointment.

R Bromol 15 grains;
Sterilized olive oil 450 "

For inunctions.

Treatment of Trachoma.—The *Riforma medica* for March 16th ascribes the following to Blöbaum:

R Sulphate of copper,
Salicylic acid,
Hydrochloride of co- } of each, 15 grains;
caine,
Vaseline 150 "

M.

For external use. The existence of corneal ulcerations does not contraindicate the use of this ointment.

A Substitute for Salicylate of Sodium.—The *Riforma medica* credits the following prescription to Descoompan for use in cases where there is an intolerance of salicylate of sodium:

R Salicylate of lithium $7\frac{1}{2}$ grains;
Sulphate of quinine, from $1\frac{1}{4}$ to 3 "

M.

For one powder. Four powders may be taken daily.

The Treatment of Gastralgia.—The *Riforma medica* for March 18th attributes the following to Hare:

R Chloral hydrate 3 grains;
Sodium hyposulphite 6 "
Peppermint water 60 "

M.

To be repeated as often as necessary on the occurrence of attacks. [Taking care as to the amount of chloral administered.—Ed. N. Y. M. J.]

An Antarthritic Powder.—The *Riforma medica* for March 20th gives the following formula:

R Benzene acid,)
Lithine carbonate,) each 15 part;
Sodium bicarbonate 20 "

M S: A large pinch to be taken before each meal

An Application for Urticaria.—Wolff (*Clinique de médecine de Bruxelles*, 1898; *Riforma medica*, March 21, 1899) gives the following as an American formula:

R Prepared calamine, $\frac{1}{2}$ each 6 parts;
Zinc oxide,
Carbolic acid 20 "
Lime-water 60 "
Rose water 130 "

M. For children, the proportion of carbolic acid should be reduced according to the age.

Ciaburri's Antichlorotic Pills.—According to Giofredi and Maramaldi (*Medico pratico; Clinica moderna*, March 15th), these pills are superior to Bland's. The formula is:

R Ferrous sulphate, $\frac{1}{2}$ each $1\frac{1}{2}$ grain;
Potassic carbonate, }
Quinine sulphate, } each $\frac{3}{4}$ "
Nux vomica, }
Arsenous acid 0.03 "

M.

Water Kefir: a Hygienic Drink for the Army.—The *Journal of the American Medical Association* for February 4th, citing the *Presse médicale* for January 7th, says that kefir made with milk is the constant beverage of the inhabitants of the Caucasus, and a modified kefir made with water, sugar, and kefir grains produces in six days a sparkling, refreshing drink containing 1.4 grammes alcohol, 16 of sugar, and 2.10 of carbonic acid to the litre, resembling cider in its appearance, with an acid, slightly vinous taste. The expense is less than a sou (about one cent) a litre, and Surgeon-Major Carteret, of the French army, has found it a most excellent and popular hygienic, tonic, and appetizing drink for the soldiers in his regiment. He observes that the kefir is not a good culture medium, and is therefore healthier than the water from which it is made. The formula is two litres of water to one litre of kefir grains and fifty grammes of brown sugar. Stir in an open pitcher. After three days, stir again, strain, and bottle, fastening the corks as for champagne. Drink, after three days in the bottle. The kefir grains can be used again and again, and if well dried can be put away to keep for months.

Amylene Chloral.—According to the *Journal de chimie et de pharmacie* (cited in the *Gazzetta medica lombarda* for February 15th), under certain conditions chloral and amylene hydrate combine to form dimethylethylcarbinol chloral, or amylene chloral, which is a colorless, oily liquid, of the specific gravity of 1.24, having the odor of camphor and a burning taste. It is insoluble in cold water, but soluble in hot water, splitting up into its component parts. It mixes in all proportions with alcohol, ether, acetone, and the fixed oils. It is a hypnotic, and, it is said, may be employed without inconvenience. The dose is not given.

The Rhinoceros, the Tiger, and the Stag as Sources of Drugs in Siam.—According to the *Gazzetta medica de Paris* for March 11th, the skin and horns of the rhinoceros, the claws, teeth, brain, and bile of the tiger, and the young antlers of the stag are highly esteemed as articles of the materia medica.

Calomel in the Treatment of Hæmorrhoids.—Dr. Kleivone (*Verh.*, 1899, No. 2, *Gazzetta de' ospedali e delle cliniche*, March 11th) recommends suppositories of five grains of calomel with a no better

NEW YORK, SATURDAY, APRIL 15, 1899.

"CUPRIC ELECTROLYSIS" IN THE TREATMENT OF
OZÆNA.

PRECISELY what takes place in the process termed "cupric electrolysis" is not easy to explain or, for that matter, to understand. It is probable, however, that the chief occurrence, from the therapeutical point of view, is the formation of copper compounds which, owing to their nascent state, have medicinal virtues that one might seek for in vain in our ordinary preparations of copper. The procedure itself, as employed in the treatment of ozæna, is simple enough. A copper needle connected with the positive pole of a galvanic battery is inserted into the inferior or the middle turbinated body, another needle (of platinum or steel) connected with the negative pole is passed into the septum, and a current of from three to ten milliamperes is turned on and allowed to pass for about ten minutes.

In the March number of the *Edinburgh Medical Journal* Dr. P. M'Bride gives the history of this method of treating ozæna, which, originally suggested by Jonslain eight or ten years ago, has practically been confined to certain rhinologists of France and Belgium. Dr. M'Bride gives also his own experience with it, including short accounts of eight cases occurring in the out-patient service of the Royal Infirmary. Usually, he says, the patients complained but little of pain or of disagreeable after-effects, but in the case of a private patient there was a good deal of suffering from neuralgia, swelling of the eye, and general disturbance for a day or two. Four of the eight cases were practically cured—that is, the factor was done away with, although in most of the cases the atrophy remained—and the patients were free from trouble for periods as long as eighteen months. In one other case there was decided improvement; in another there was an apparent cure for some months, but then syringing had to be resumed; and in the two remaining cases there was improvement, but it lasted only for a few weeks. Like most other observers, the author noted that the application of electrolysis to one nostril alone often produced benefit, temporary or lasting, on both sides.

Dr. M'Bride is quite prepared to admit that the

results achieved in these cases may have been beyond what can reasonably be expected on an average; still, he says, they prove that in "cupric electrolysis" we have a valuable therapeutic resource, probably the most valuable that has yet been suggested, for ozæna.

PHANTOM TUMORS.

PHANTOM tumors, or "vanishing tumors," as they were termed at the meeting, were lately under discussion by the Harveian Society of London (*Lancet*, March 11th). One of the speakers, Dr. Leonard Guthrie, displayed considerable ingenuity in accounting for the occasional disappearance of tumors. Mr. Alban Doran had remarked that he had never known of a case of exploratory incision in which a real sarcoma or carcinoma was detected that had resulted in the least benefit to the patient. This was apropos of laparotomy in cases of tuberculous peritonitis.

Dr. Guthrie said he believed there were well-authenticated instances of the spontaneous disappearance of tumors, both malignant and benign. Tumors, he said, were dependent on their blood supply for their growth; if the supply was cut off, the tumor would waste. Possibly, he suggested, the success which occasionally attended the treatment of cancer with drugs depended on their action as vascular astringents. In the last century, he said, cancerous breasts were treated by the application of toads, which were supposed to suck the venom from the ulcers. Dr. Lauder Brunton had compared the action of phrynin, the active principle of the secretion of the toad's skin, to that of digitalis and erythrophlein [erythrophleine?], which were powerful vascular astringents. Phrynin had, moreover, a benumbing action on sensory nerves, like aconite; hence, though the remedy seemed absurd, it might possibly have been beneficial in some cases. A similar explanation might be offered of the effects of other drugs vaunted as cures for cancer, such as calcium carbonate, Chian turpentine, and cinnamon, which latter contained tannic acid. The success which sometimes followed oophorectomy for "inoperable" cancer of the breast was due possibly to the profound effect produced by that operation on the whole of the sympathetic system. Perhaps in such cases a local dilatation of vessels in a cancerous region gave place to a local constriction. The effects of strong mental emotion on the sympathetic should not be forgotten; they might account for the miraculous cures of cancer and other tumors at Lourdes and elsewhere. Dr. Guthrie expressed his conviction

that all methods of treatment based on these assumptions were at best uncertain and their effects but temporary, and they were available only in "inoperable" cases.

VAGINISMUS AND VULVAR HYPERÆSTHESIA.

In the *Lyon médical* for January 15th M. Jaboulay grouped under the name of pelvic neuralgia a series of subjective disorders affecting for the most part the uterus and the ovaries, but sometimes the external genital organs also, causing vulvar hyperæsthesia and vaginismus without any discoverable lesion, even in rebellious cases and those of long standing. Hysterectomy and oophorectomy, being grave and mutilating operations, are absolutely contraindicated in such cases, efficacious though they may be in some instances. In two very old and rebellious cases M. Jaboulay has succeeded in effecting a cure by excising the sacral chain of sympathetic ganglia or by dividing and tearing the anterior branches of the sacral plexus. This he accomplishes through an incision in the sacrococcygeal region.

In the same journal for January 22d M. Aubert, commenting on M. Jaboulay's communication, calls to mind one of his own, published about twenty years ago, in which were set forth the good effects of dilatation of the sphincters and stretching of the muscles. He mentions in particular the case of a young woman who, although four months married, had been unable to take part in coitus. Under anaesthesia, the vulvo-vaginal ring and the anus were widely dilated, and in a week complete sexual intercourse was accomplished with less pain than the patient had experienced during the former fruitless attempts at it. Impregnation occurred, and the woman's conjugal relations were thenceforward regular and normal.

We think M. Aubert is quite right in bringing the dilatation treatment forward again, not as a novelty of course, for he does not allege that it was original with him, but expressly states that the idea had been suggested several years before by Visca in a Paris thesis. M. Aubert explains the efficacy of the dilatation treatment by pointing out that nerves as well as muscles are stretched in the process, and he correctly maintains that it possesses the advantage of being quite within the power of any practitioner without special operative skill to carry out. To this it may be added that simple procedures are to be preferred to intricate operations in all but exceptional cases. We are speaking, of course, of cases unaccompanied by grave organic lesion or serious danger to life.

THE EFFECTS OF PROTRACTED INSOMNIA.

AN Italian physician, Dr. Giulio Tarozzi, of Pisa, has been studying the effects of enforced loss of sleep on four dogs (*Rivista di patologia nervosa e mentale*, January; *Indépendance médicale*, March 29th). The animals were watched night and day, and all possible means of rousing their attention and annoying them were taken to prevent their sleeping. Even at that, however, absolute insomnia was not secured, although practically the poor creatures were kept awake until death occurred. The fatal termination is described as taking place rather rapidly and as being preceded by a sudden and decided rise of temperature, followed by a gradual fall. The amount of sulphates and phosphates in the urine showed no characteristic change during the experiments; the chlorides were diminished in every instance during the few days preceding the animal's death. It is to be hoped that Dr. Tarozzi's results, meagre as they are, will be accepted without the repetition of so cruel an experiment, one well calculated, it seems to us, to play into the hands of those well-meaning but misguided people, the antivivisectionists.

A MEDICAL WOMAN ON THE CORSET.

AMONG the Paris theses for the year 1898-'99 is one by Mme. Tylicka entitled *Du corset, ses méfaits au point de vue hygiénique et pathologique*. From a brief summary in the *Gazette hebdomadaire de médecine et de chirurgie* for March 26th we learn that Mme. Tylicka lays stress upon the respiratory, circulatory, and digestive troubles that the corset produces in the long run. She would do away with it entirely, and substitute a waistcoat of heavy linen adjusted to the stature, reaching only to the waist, buttoned in front, and fortified with two whalebones on each side to sustain the breasts.

TYPHOID FEVER AS A CAUSE OF EPILEPSY.

A WRITER in the *Revue de médecine* for February, M. Dide, considers the part that may be played by typhoid fever in the aetiology of epilepsy. It appears from a summary of his article in the *Indépendance médicale* for March 29th that his observations go to show that typhoid fever not infrequently evokes epilepsy in persons of a neurotic predisposition, and, furthermore, that if it is severe enough it occasionally gives rise to epilepsy in those who are free from such a tendency, so far as can be ascertained.

A NEWBORN INFANT'S DEATH FROM UNAVOIDABLE NEGLECT.

M. PERRIN DE LA TORCHE recently related at a meeting of the Paris Society of Legal Medicine (*Indépendance médicale*, March 22d) a curious case of syncope during labor that came under his observation twenty-five years ago, one in which a judicial tribunal exercised well-deserved clemency based on a hint contained in his report as medical examiner. A poor seamstress, occupying lodgings that were rather isolated, was taken with labor pains, and not long afterward her neighbors found that her child was dead. An investigation had to follow. The story told by the forlorn mother, a weakly girl affected with Pott's disease, was that when labor had progressed so far that the child's head was distending the vulva with each pain she had seized her sewing

scissors and deliberately cut the perineum. And that was the last she remembered. When she regained consciousness, she found her baby between her thighs. She cut the umbilical cord, tied it, dried the child, and called in the neighbors. Then it was that the infant was found to be dead. Her story of her having incised the perineum was corroborated by an examination of the parts, but the rest of what she had to say seems to have been admitted as true on the strength of M. Perrin de la Touche's suggestion that she might have fainted immediately after making the cut—and well it may have been.

THE PRESENT STATUS OF THE CITY BOARD OF HEALTH'S COMMERCIAL OPERATIONS.

THERE are what we interpret as indications that, notwithstanding the defeat of the Collier bill, the board is inclined to recede from the stand it has taken in defiance of the great unwritten law that public money must not be used in competition with the citizen's capital and labor. The question of such competition, as we have said before, is not one with which the medical profession feels it its particular province to concern itself, but, since the board has thought fit to bring certain medical men's opinions to bear in support of its contention, it is quite in order, we think, for the profession at large to let it be known that the opinions thus employed by the board are not those entertained by the majority of physicians. If, as we surmise, the board is inclined to abandon its commercial operations, that inclination can in no way be more strengthened than by physicians' urging it. At the same time let it be urged that the board's appropriation should be made large enough to do away with the plea that the board has to fall back on sales of its products to eke out the resources required for its legitimate work.

THE FUNCTIONS OF THE LYMPHATIC GLANDS.

THERE is perhaps nothing particularly new in an article by M. Bezancon and M. Labbé (*Presse médicale*, February 15th; *Indépendance médicale*, March 29th), but it seems to us to be very well put. By its follicular system, they say, the normal lymphatic gland takes part in the formation of the leucocytes, and this function becomes heightened in activity when hyperleucocytosis is called for by an invasion of pathogenic germs. Moreover, the gland "does police duty" for the lymphatic vessels, attacking bacteria that have escaped the action of the leucocytes elsewhere and freeing the lymph from cellular and pigmentary debris.

ONE OF THE PENALTIES OF BEING FAMOUS.

THE Paris *Figaro*, speaking of the case of a literary woman, Mme. Séverine, on whom a successful operation was recently performed in a sanitarium by Dr. Pozzi, "professeur agrégé à la Faculté de médecine, chirurgien de l'hôpital Broca, sénateur de la Dordogne," intimates that it is destined to become celebrated because the president of the French Republic sent to inquire how the patient was getting along. The *Gazette médicale de Paris* for March 25th alludes to the newspapers' accounts of the case, and takes occasion to print a wretched portrait of the lady and an almost equally wretched one of Dr. Pozzi. Verily we have no monopoly of "yellowness" in the United States.

INFLUENZA AND DISEASE OF THE VERMIFORM APPENDIX.

THAT an attack of influenza sometimes plays a part in engendering appendicular inflammation is admitted by many observers, but few are prepared, we imagine, to go so far as M. Faisans went recently when he declared at a meeting of the Medical Society of the Hospitals (*Indépendance médicale*, March 29th) that influenza was the real cause of disease of the appendix. He based his assertion chiefly on the alleged increased frequency of appendicular disease during the last twelve years, a period characterized by frequent epidemics of influenza. An outbreak of influenza, he said, was sure to be accompanied or followed by the occurrence of numerous cases of inflammation of the appendix.

THE SO-CALLED EUNUCHS OF AUSTRALIA.

A PRACTICE said to prevail among the aborigines of Australia may perhaps be set down as an improvement upon the artificial establishment of barrenness in women in cases in which procreation is undesirable. Dr. Hösbert (*Janus; Lyon médical*, March 19th) states that boys approaching the age of puberty are subjected to an incision that results in a urethro-perineal fistula, and the result is that when they copulate the seminal fluid is apt to stop short of the vagina. The procedure is not radical, but it has its merits.

ARTIFICIAL SERUM IN THE TREATMENT OF TYPHOID FEVER.

THE typesetters of Florence seem to have taken special interest in the treatment of typhoid fever lately, as the result of an epidemic affecting the members of their craft. Accordingly, under the auspices of the Florentine Typographical Society, Dr. Giglioli and Dr. Calvo (*Giornale internazionale delle scienze mediche*, March 15th) have tried subcutaneous injections of artificial serum in that disease, in all stages, with palliative but not curative results. Perhaps the use of a physiological solution of salt would have answered as well.

MEDICAL SUPERSTITIONS.

THE *Clinical Reporter* for March, quoting the *Boston Medical and Surgical Journal* of uncertain date, gives a list of popular superstitions on medical subjects. It is just possible that some of these superstitions may enshrine a grain of truth, as, for instance, that said to be prevalent in Massachusetts, that "pregnant women must avoid the smell of paint, or they'll miscarry." We have heard a good deal of late about lead as an abortifacient; may there not be some real basis of truth in the superstition? We have only to consider the amusement with which years ago we used to read the ancient "pharmacopœias" issued by prominent physicians—*e. g.*, that of Dr. Salmon published some two centuries or so ago—particularly in regard to what is now known as opotherapy, to realize that empirical though their knowledge was, their crude methods had after all a basis in scientific truth. Instead of deriding these superstitions wholesome, would not the wiser part lie in a careful examination of them with a view to extracting such grain as may be concealed in the chaff? As an instance, in Salmon's pharmacopœia before referred to, crushed

spiders are given as a remedy for "fever and ague." Within recent times arachnidine has been vaunted as a remedy for intermittent fever; and, although it has failed to fulfill all that was expected of it, there can be no doubt that it does possess antiperiodic properties.

DANGER IN THE KINEMATOGRAPH.

It is not, perhaps, generally known that the celluloid rolls used in the kinematograph are not only inflammable but, under certain circumstances, also explosive. The *Lancet* for March 11th comments on a serious accident which recently occurred in a London theatre, due to some defect in the electric wires, causing the film to explode, wrecking the apparatus, terribly burning the electrician, and burning the clothes of a bystander, who, however, was fortunate enough to escape personal injury. Had the accident occurred, as the *Lancet* very justly points out, in a full house, instead of only during a rehearsal, it requires no great stretch of imagination to suppose that in all probability a panic would have ensued, proving infinitely more disastrous than the direct effects of the explosion. The increasing use of the kinematograph in places of public amusement—and it is undoubtedly a valuable adjunct not only to amusement but also to instruction—renders it highly desirable that some effective supervision should be exercised over such presentations to minimize the risk of accidents. Could not all such performances be licensed by the fire department, who should undertake the work of supervision, as elevators are constantly overhauled to lessen the risk incident thereto?

THE OUTSIDER'S VOLUNTEERED PAPER.

We may be permitted to throw out the suggestion that the medical societies that meet only once a year would be doing their members justice and themselves as organizations credit if they were to ignore the non-member who volunteers to present a paper. It is undoubtedly conducive to the success of a meeting if by invitation a person of weight in the profession takes part in it to the extent of reading a paper and joining in the discussions; but this is not what we have in mind. Such persons do not offer to read papers. The man who does is only too apt to be one who seeks to advertise himself. But, whether he is of that sort or not, he takes up time that properly belongs to the members. We all know that the programme of such a meeting is generally of undue length, so that justice can not be done to it. Papers often have to be presented only in abstract or even by title, on account of lack of time for their adequate presentation and discussion; and this glutting of the programme is intensified by the admission of papers proffered by outsiders.

THE RENAISSANCE OF MINOR GYNÆCOLOGY.

The time seems to be at hand in which a physician who ministers effectively in the field of gynæcology will receive some credit from the laity without need of being known as a laparotomist. For a time of years, minor operations, often, it is to be feared, undertaken with but slight reason, have swamped all other services in this field, in the estimation of patients and their friends. The change that appears to be coming will be in the interest of sound and conservative practice, and is to be welcomed.

WINE OF CINCHONA AS A TIPPLE.

WINE of "calisaya," as it is commonly termed by its hypocritical consumers, is doubtless taken steadily and in great measure stealthily as a tippie. In the *Tribune médicale* for March 29th Dr. A. Baratrier declares that this species of tipping is far more prevalent than is commonly supposed, and he points out what he considers some of its particular dangers, not the least of which is connected with the bad quality of wine often employed in concocting the preparation.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 8, 1899:

DISEASES.	Week ending Apr. 1.		Week ending Apr. 8.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	8	6	19	7
Scarlet fever.....	173	16	156	11
Cerebro-spinal meningitis.....	0	11	0	10
Measles.....	259	12	267	14
Diphtheria.....	175	56	185	29
Croup.....	22	8	12	9
Tuberculosis.....	251	156	159	166
Small pox.....	1	0	2	0
Chicken-pox.....	27	0	21	0

Aristotle Once an Apothecary.—The *Bulletin of Pharmacy* for April says that, in a discussion on "aloes" before the Pennsylvania Pharmaceutical Association, Dr. A. W. Miller remarked that the first intimation of obtaining this drug, and supplying it originally to invalids, was due to the investigation of a former druggist. "Aristotle," he said, "at one period of his life, kept a drug store in Athens, before he became one of the most eminent philosophers of Grecian antiquity. After he had spent his patrimony in the pursuits of liberal studies, he opened a drug store in Athens; and subsequently, on account of the renown that had followed his labors, he became the tutor of Alexander. When Alexander found no further worlds to conquer, Aristotle suggested to him that he had not yet secured possession of Sumatra [Socotra?], the most precious isle of the ocean, and the one which produced the most valuable aloes."

We may add that the *Ethics* of Aristotle is better known than his connection with aloes; there are, however, in these days druggists, and doctors, too, for that matter, whose aloes is much better known than their ethics.

Science and Courtship. A writer, dating from Umeåborg, Finland, writes to the *London Sporting Times* for March 18th, saying that he thought the following advertisement, translated from a local Swedish paper, might interest that journal:

"A rich young merchant is looking for an intelligent lady with good health, as a companion for life. Replies addressed to B will only be taken notice of if accompanied by a portrait, an X-ray picture, and a photo of the interior of the stomach."

The writer adds: "You will notice we are very particular in Finland."

Here is a hint for some of our "stand farm" marriage legislators.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general of the United States Marine-Hospital Service for the week ending April 8, 1899:

Small-pox—United States.

Mobile, Ala.	Mar. 24-26	3 cases.	
Washington, D. C.	Mar. 31-Apr. 5	6 "	
Jacksonville, Fla.	Mar. 25-Apr. 1	1 case.	
Key West, Fla.	Mar. 24-29	3 cases.	
Chicago, Ill.	Mar. 24-31	3 "	
Alexandria, La.	Mar. 29	9 "	
New Orleans, La.	Mar. 25-Apr. 1	65 "	2 deaths.
Baltimore, Md.	Jan. 18-Apr. 1	12 "	1 death.
Beaver County, Pa.	Mar. 12-30	1 case.	
Bedford County, Pa.	Mar. 12-30	1 "	
Fayette County, Pa.		15 cases.	
Somerset County, Pa.		1 case.	
Alexandria, Va.	Mar. 31-Apr. 2	1 "	
Newport News, Va.	Mar. 27-Apr. 1	20 cases.	
Norfolk, Va.	Mar. 25-31	33 "	
Portsmouth, Va.	Mar. 25-31	27 "	1 "
Spokane, Wash.	From first appearance to Mar. 28		4 deaths.

Infection from Los Angeles, Cal.

Small-pox—Foreign.

Bahia, Brazil.	Mar. 4-11	2 cases.	
Rio de Janeiro, Brazil.	Feb. 17-24	2 "	1 death.
Hongkong, China.	Feb. 4-11	2 "	1 "
Hongkong, China.	Feb. 11-18	3 "	1 "
Seoul, Korea.	Feb. 25	Epidemic; many cases and many deaths.	
Cairo, Egypt.	Feb. 18-Mar. 11		3 deaths.
Liverpool, England.	Mar. 11-18	1 case.	
London, England.	Mar. 11-18	1 "	
Paris, France.	Mar. 11-18		1 death.
Athens, Greece.	Mar. 11-18	7 cases.	3 deaths.
Calcutta, India.	Feb. 18-25		1 death.
Madras, India.	Feb. 24-Mar. 3		2 deaths.
Mexico, Mexico.	Mar. 19-26	8 "	3 "
Nagasaki, Japan.	Feb. 27-Mar. 6	1 case.	
Moscow, Russia.	Mar. 4-11	18 cases.	2 "
Odessa, Russia.	Mar. 11-18	3 "	
St. Petersburg, Russia.	Mar. 11-18	5 "	1 death.
Constantinople, Turkey.	Feb. 27-Mar. 6		11 deaths.
Constantinople, Turkey.	Feb. 6-13		18 "
Smyrna, Turkey.	Feb. 26-Mar. 5		1 death.
Yambo, Turkey.	Mar. 29	Small-pox raging.	

Yellow Fever.

Bahia, Brazil.	Mar. 4-11	4 cases.	2 deaths.
Rio de Janeiro, Brazil.	Feb. 17-24	65 "	41 "
Vera Cruz, Mexico.	Mar. 22-30		2 "

The West London Medico-chirurgical Society.—The *British Medical Journal* announces that Dr. William Osler will deliver the Cavendish lecture before the society on June 13th.

The Buffalo Academy of Medicine. At the last regular meeting, on Tuesday evening, the 11th inst., the following papers were read: Hereditary Syphilis, by Dr. A. E. Dicht; and Nasal and Cranial Diseases, by Dr. William C. Krauss.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 8th inst., the following papers were presented for discussion: A Case of Tetanus following Vaccination, by Dr. F. E. Chase; and Unconquered Crêpe and its Use in a Case of Septicæmia Post abortum, by Dr. Hugo Sumner.

The Richmond Academy of Medicine and Surgery.—At the last meeting, on Tuesday evening, the 11th inst., Dr. J. Travis Taylor opened the discussion with a paper on Erythema Scarlatinoïdes.

The Collier Antitoxine Bill Defeated.—We learn that this bill was last week thrown out by the New York Senate.

Changes of Address.—Dr. Albert H. Buck and Dr. Robert Lewis, Jr., to No. 48 West Fortieth Street, New York; Dr. Schmitz, to No. 6352 Monroe Avenue, Chicago.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 1 to April 8, 1899:*

APPEL, AARON H., Major and Surgeon, will proceed to Galveston, Texas, for muster out of the First Texas Infantry.

BRATTON, THOMAS S., First Lieutenant and Assistant Surgeon, will proceed to Savannah for duty.

CLENDENIN, PAUL, Major and Chief Surgeon of the United States Volunteers. The order honorably discharging him is revoked, and he is relieved as chief surgeon, Second Division, Seventh Army Corps. He will then proceed to Santiago as commanding officer of the general hospital there.

COFFIN, HAROLD L., Acting Assistant Surgeon, will proceed from Washington to Jefferson Barracks, Missouri, to accompany Light Battery E, First Artillery, to Manila.

DOLZ, WILLIAM, Major and Brigade Surgeon, is honorably discharged, to take effect April 5th.

DRAKE, C. M., Acting Assistant Surgeon, will proceed to Jefferson Barracks, Missouri, to accompany Light Battery E, First Artillery, to Manila.

FITZPATRICK, CHARLES, Acting Assistant Surgeon, will report to WAKEMAN, WILLIAM J., Major and Brigade Surgeon, attending surgeon and examiner of recruits in Philadelphia, for duty as his assistant in the medical examination of recruits.

GARDNER, EDWIN F., Major and Surgeon, is detailed as a member of a board appointed to meet at Denver for examination for promotion.

GIRAUD, ALFRED C., Lieutenant-Colonel and Chief Surgeon, will proceed to the Presidio of San Francisco.

HARVEY, PHILIP F., Major and Surgeon, is detailed as a member of the examining board appointed to meet at St. Paul, *vice* TILTON, HENRY R., Lieutenant-Colonel and Deputy Surgeon-General.

HYDE, L. W., Acting Assistant Surgeon, will proceed to Hartford, Connecticut, and report to HOWE, WALTER, Captain, Fourth Artillery, for duty.

LLOYD, CYRUS D., Acting Assistant Surgeon, is detailed as a member of the examining board appointed to meet at Fort Leavenworth, Kansas, *vice* TOBNEY, GEORGE H., Major and Surgeon.

MUNN, CURTIS E., Major and Surgeon, is detailed as a member of the board appointed to meet at Denver for examination for promotion.

PERSONS, ELBERT E., Acting Assistant Surgeon, will proceed to Governor's Island, N. Y., for assignment with Batteries L and M, Fifth Artillery, and accompany these batteries to Manila.

SIMS, GEORGE K., Acting Assistant Surgeon, will accompany the battalion, Sixth Artillery, to Honolulu.

TAYLOR, RALPH L., Acting Assistant Surgeon, is relieved from the Department of Pinar del Rio, and will proceed to New York for assignment to duty on a government transport.

Society Meetings for the Coming Week:

MONDAY, April 17th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, April 18th: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Passaic, N. J., County Medical Society (annual); Baltimore Academy of Medicine.

WEDNESDAY, April 19th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Middlesex, Massachusetts, South District Medical Society (annual—Waltham); Windham, Connecticut, County Medical Society (annual—Plainfield); Philadelphia County Medical Society.

THURSDAY, April 20th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Tolland, Connecticut, County Medical Society (annual); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

FRIDAY, April 21st: New York Academy of Medicine (Section in Orthopaedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynaecological Society.

Births, Marriages, and Deaths.

Married.

BAKER—CHEATHAM.—In Louisville, Kentucky, on Wednesday, April 5th, Mr. James Reed Baker and Miss Elizabeth Van Dyck Cheatham, daughter of Dr. William R. Cheatham.

BROWN—CHASE.—In Scranton, Pennsylvania, on Wednesday, April 5th, Dr. Harry MacVeagh Brown and Miss Olive MacIntosh Chase.

DAVIS—CARTER.—In New York, on Thursday, April 6th, Dr. Charles E. Davis, of Albany, and Mrs. Mary Scott Carter.

DEANE—LOWME.—In Plainfield, New Jersey, on Wednesday, April 5th, Mr. Julian S. Deane and Miss Maude Myra Lowrie, daughter of Dr. Henry H. Lowrie.

EMMETT—ASHMAN.—In New York, on Thursday, April 6th, Dr. Frank Newcomer Emmett, of Haverstown, Maryland, and Miss Lillian De Forest Ashman.

PINCUS—LAYMAN.—In New Orleans, on Tuesday, April 11th, Dr. Sidney E. Pincus, of Memphis, and Miss Gussie Layman.

SMITH—FRIEDERICH.—In Syracuse, N. Y., on Wednesday, April 5th, Dr. Andrew F. Smith and Miss Annie Cooper Friederich.

SULLIVAN—WADSWORTH.—In Boston, on Saturday, April 8th, Mr. T. R. Sullivan and Miss Lucy Wadsworth, daughter of Dr. Oliver F. Wadsworth.

VAN NOSTRAND—SMITH.—In New York, on Thursday, April 6th, Dr. William Van Nostrand and Miss Anna Leone Smith.

WADE—KNIGHT.—In Boston, on Wednesday, April 5th, Mr. George K. B. Wade and Miss Theodora Irving Knight, daughter of Dr. Frederick Irving Knight.

Died.

BOWEN.—In Boston, on Friday, April 7th, Dr. Seranus Bowen, in the sixtieth year of his age.

CHESEBOROUGH.—In Summit, N. J., on Thursday, April 6th, Dr. Nicholas Cheseborough, in the seventy-eighth year of his age.

NELSON.—In Danville, Virginia, on Thursday, April 6th, Dr. William Nelson.

RIVES.—In Washington, D. C., on Sunday, April 2d, Dr. Wright Rives, United States Army, in the twenty-seventh year of his age.

RUTHERFORD.—In Houston, Texas, on Friday, March 31st, Dr. Robert Rutherford, in the sixtieth year of his age.

Letters to the Editor.

THE TERM SYCOSIS.

126 EAST TWENTY-NINTH STREET, NEW YORK, April 1, 1899.

To the Editor of the New York Medical Journal:

SIR: The article of Dr. Regensburger, of which you speak in to-day's editorial of your most excellent journal, may be highly interesting, as you say, but his proposal of the term *dermatitis barbe* is a most unfortunate one. First of all, it is a hybrid term, and, secondly, it is impossible; we might as well speak of *dermatitis of the straw hat*. The synonymous term in existence already, *acne mentagra*, although hybrid, is after all preferable to *dermatitis barbe*.

A. ROSE, M. D.

*** We recognize, of course, that *dermatitis* is Greek and *barbe* is Latin, but hybridity, as we understand it, is a quality only of single words constructed from more than one language. As to our correspondent's other objection, what would he say of *hydrocele of the trousers*?

A PHYSICIAN IN DISTRESS.

161 WEST ONE HUNDRED AND TWENTY SECOND STREET,
NEW YORK, April 2, 1899.

To the Editor of the New York Medical Journal:

SIR: The unusual circumstances pertaining to the case I present to you seem a fitting excuse to solicit your cooperation in obtaining relief for a physician who is in sore distress. Dr. Edward von Bonhoff some three years ago was taken ill, and from his disease was left deformed for life, and is now a homeless object of charity. His unfortunate wife is in an asylum hopelessly incurable, and his two children are in the care of friends.

I have been requested to hold a fund subscribed by some medical gentlemen, but the amount collected has been so small that it is now exhausted, keeping his body and soul together during the winter. We hoped to collect a sufficient amount to enable the doctor to sail for Honolulu, where he has some friends and where, under a tropical and equable climate, he would soon support himself despite his physical condition, for he is highly

educated, speaking the German, Spanish, and Danish languages.

Whoever is generously inclined to assist may send contributions to the undersigned.

M. C. O'BRIEN, M. D.,
Ex-Recording Secretary of the New York County
Medical Association.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XIV.

RIGHTS AND LIABILITIES OF THIRD PARTIES.

(Continued from page 502.)

Post-mortems at Coroner's Inquest.—The right of the physician to recover from the county for services in making a post-mortem examination when summoned for that purpose by the coroner is in many States regulated by statutes which vary not only in their form of expression but in the substance of their provisions as well, and which are the subject of such frequent change as to render an extended examination of them of no lasting value. The common-law liability of the county and also the meaning of many of these statutes have been the subject of judicial examination on numerous occasions and, as these cases serve to illustrate the policy of the law with regard to the compensation of physicians for this class of services, they are examined to some extent.

Upon the common-law liability of the county for the physician's fee for services at a coroner's inquest the supreme court of Arkansas, in a recent case, expressed itself as follows: "The statute makes it his (the coroner's) duty to use *all proper means* to ascertain the truth concerning the death of the person over whose body he is required to hold an inquest. It sometimes occurs that the cause of death can only be ascertained by skillful physicians, and by them only by making an autopsy. How can the coroner discharge the duty imposed on him in such cases? He may summon the physician to testify and compel him to swear to his opinion on a superficial view of the body, but can not compel him to touch it, or do the more nauseous and dangerous work of opening it, because such an act is not within the office of a witness. The coroner is not expected or required to make the autopsy with his own hands. It is not within the line of his official duties, and no fee is allowed for such work, for the reason stated. Yet he is authorized to ascertain the truth concerning the death. The conclusion is unavoidable: he must in such cases employ a physician to make the autopsy and ascertain the cause of death, as in that case it would be the only proper means by which the truth could be ascertained." Commenting further upon the liability for the payment of the physician's fees for such operation, the court says: "Is he (the coroner) or the county responsible for the services of the physician? . . . Such services, though ancillary to the purpose of some inquests, are not official, and consequently were not considered by the legislature when it fixed the fees of

coroners. But there is not only no fee fixed, but no fund set apart to the coroner for such expenses. To hold, then, that he is responsible, under such circumstances, would be to require him to contribute so much gratuitously to the administration of justice and to the enforcement of the laws. . . . Such a requirement would be unjust and oppressive, and contrary to the spirit of our laws. As a rule, the counties are responsible for the expense of the administration of criminal laws. Both justice and policy demand an adherence to the rule in this case, and that the county should pay a reasonable compensation for such services when needed and performed—that is to say, what they are reasonably worth."*

This case is cited with approval and followed in a later Arkansas case decided in 1895.† In 1865 the supreme court of New York held that where a physician was employed by a coroner to perform a post-mortem examination at the inquest, with no special agreement that he should receive his compensation from other source than the coroner, his only recourse was to compel that official to pay his fee; but that the coroner had the right to recover from the county the amount paid to a physician in such a case.‡ The legislature, however, passed an act in 1874 making the physician's fee in such a case a direct charge against the county. Since the passage of this act the physician must look to the county for his pay, as the coroner is released from this liability.§

In California the liability of the county for the payment of the physician's services in making post-mortems is recognized, but the legislature has enacted a law providing that "the board of supervisors must not hear or consider any claim in favor of an individual against the county unless an account, properly made out, giving all the items," is presented to the board. A claim of a physician which was properly verified by the coroner was presented to the board for allowance. The account was for "making a trip from Petaluma to Timber Cove, and making a post-mortem examination of the body of —, and taking the stomach of said deceased to San Francisco for analysis." This account was held not to fulfill the requirements, as it did not give "all the items." It should have given the number of miles traveled in going from Petaluma to Timber Cove, and the length of time consumed in making the post-mortem examination; also the number of miles traveled, the time consumed, and the expense incurred in taking the stomach to San Francisco for analysis.||

In Colorado the right to collect from the county is fixed by statute, which provides that where the "jury shall deem it requisite," the coroner may summon one or more physicians, and may allow a reasonable compensation subject to the confirmation of the board of county commissioners. The wording of this statute does not, however, render it incumbent upon the physician, when summoned, to inquire whether or not the jury deemed it requisite to make such an examination. It is his duty when so summoned to obey the summons, and he has a right to assume that the coroner acted

|| Christie vs. Board of Supervisors of Sonoma Co., 60 Cal., 164.

correctly in summoning him, and to rely upon such official act.*

In Indiana the liability of the county has been recognized for many years. The supreme court said in 1852: "We have no doubt that in a case where a post-mortem examination is really necessary the coroner may, by his employment, bind the county to the payment for a sufficiency of professional skill to make the examination. To that extent, at least, he must be the agent of the county."† The matter is now regulated in the State by statute, which provides that when a surgeon or physician is required to attend an inquest held by a coroner, and make a post-mortem examination, the coroner shall certify such service to the board of county commissioners, who shall order the same paid out of the county treasury. The fact that an inquest is conducted by a justice of the peace, who is there authorized to perform all the duties of a coroner, and the physician employed and the certificate of services made out by the justice, does not in any way affect the liability of the county to pay the physician for such services.‡ Nor does it release the county from their liability in the premises because the physician is in the employ of the county to treat the poor of the asylum, nor even where the subject operated upon was during his life a pauper whom it was the physician's duty to treat when sick." Incident to the coroner's duty to hold inquests is his right not only to employ a physician to perform a post-mortem examination, but also his right to determine who that physician shall be. In the case of the Board of Commissioners of Dearborn County vs. Bond, the county commissioners employed a physician to render such services, and when the coroner refused to recognize their selection, but employed another physician and certified to his claim, the board of county commissioners refused to allow the same. The matter was appealed, and finally reached the supreme court, where the claim was allowed. Justice Best said: "This duty is imposed upon the coroner, and for the purpose of enabling him to discharge it he is empowered to employ such means and to select such physician or surgeon as in his judgment will enable him to ascertain the cause of death. The duty thus imposed necessarily confers the authority to make his own selection in the faithful discharge of his duties, and, in this respect, he can not be superseded by the board of commissioners, upon whom no such duty rests."§

There is in Indiana, by virtue of a statute, a limited exception to the general rule of liability of the county—thus: where money and other valuables are found upon the body of the deceased this property is first subjected to the payment of the expenses of the inquest.¶

The statute law of Iowa relative to the subject provides that "when he (the coroner) or the jury deem it requisite, he may summon one or more physicians or surgeons to make a scientific examination, who, in stead of witness fees, shall receive such reasonable compensation as may be allowed by the county board of supervisors."§ Under this law the amount allowed be

the county board is conclusive and can not be increased upon appeal unless fraud can be shown in fixing such amount.*

In Pennsylvania the courts hold that the coroner has the power at common law to employ a physician to perform an autopsy and to bind the county for the physician's pay. The physician when summoned is under no obligation to investigate and determine whether the inquest should be held; this is a matter left to the discretion of the coroner, and the physician may safely rely upon the mere fact that he is summoned.† Nor have the county commissioners the right to appoint a regular physician to perform such services, thereby precluding the coroner from making his own selection.‡

Upon the question of the liability of counties for the payment of the fees of physicians for performing post-mortem examinations at coroners' inquests, the courts of the State of Texas seem to stand alone. The supreme court in 1888 held that there was no such liability at common law, and that there was no statute in the State fixing such liability upon the counties.¶ Again, in 1891, the same court refused to permit a physician to recover the amount of his reasonable fee with the laconic statement: "The law permits no recovery for the services rendered."|| This construction of the law being for the second time brought to the attention of the profession by the highest court of the State, they evidently realized its injustice, and, taking the advice of the court in the case of *Fears vs. Nacogdoches County*, sought relief through legislative enactment. At the next session of the legislature, which convened on January 10, 1893, a law was enacted authorizing coroners to call in the county physician; or, if impracticable to secure his services, to summon any regularly practising physician to perform a post-mortem, and providing that the county in which such inquest is held shall pay the physician a fee of not less than ten dollars or more than fifty dollars, the excess over ten dollars to be determined by the county commissioners' court after ascertaining the amount and nature of work performed in making such autopsy.¶

Liability of Employer for Neglect, etc., of Physician.

—The liability of third parties, as contemplated heretofore in this chapter, is only that which arises in favor of the physician. Questions frequently arise as to the liability of third parties to the patient, based upon the transactions between the physician and patient. While such questions are not of direct interest to the physician, it is thought best to give them brief attention.

Employers, such as railroad companies, steamboat companies, mining companies, and the like, very frequently employ physicians to treat their wounded or sick employees; in case of negligence or malpractice of the physician, it has been a very common occurrence for the injured employee to sue his company to recover damages for the injury or loss suffered by him by reason of such negligent or improper treatment by the employer's physician or surgeon; but it is now a well-settled proposition of law that the employer is not liable for the improper treatment by a surgeon in such a case. The relation between the employer and physician

§ *Laws of Tex.*, 1893, 172.

or surgeon is not that of master and servant, which in the law implies that the servant acts under and according to the instructions of the master. In the case of employer and physician the very nature of the physician's duties precludes the possibility of this relation, as the physician is bound to exercise knowledge, skill, and judgment, and it is because he is capable of this that he is selected. It therefore follows that the employer is not responsible to his employees for the manner in which they are treated by the physician or surgeon whom he procures for them.* The law does, however, require that the employer use reasonable care in selecting a physician and surgeon of ordinary skill, otherwise he might be liable to his employee for his own negligence in making a careless selection.†

Nor is a county or other municipal corporation liable to a patient for unskillful or improper treatment by a physician while in the county hospital or similar institution.‡

While the liability of the physician to the patient can not properly be discussed under the present chapter, it is thought pertinent to state that the immunity of the third parties in the cases just referred to does not in any way relieve the physician from his liability to the patient.‡

NOTE.—The author of these articles is indebted to the *Medical and Surgical Monitor*, issue of March 15th, p. 98, for an excellent synopsis of the recent medical acts of Indiana, referred to in the letter of Dr. A. J. Miller, of Columbus, O., which was published in the *Journal* on February 18th, p. 243.

The *Monitor* says: "The medical laws in Indiana were passed in 1816, 1885, 1891, and 1897, respectively; the latter was amended March 3, 1899."

The substance of these laws as they now stand the *Monitor* presents as follows: "The applicant must be a bona fide resident of the county and State. Two freeholders must make affidavit as to the moral character of the applicant, and to the identity of the applicant and the person mentioned in the diploma. The State board of medical registration and examination will examine the same, and, if satisfactory, issue its certificate; then the county clerk is authorized to issue a license to practise medicine, surgery, and obstetrics within the State of Indiana. In case of change of residence this license may be filed with the clerk of another county and a new license obtained. A license will permit its owner to practise in any county in the State, but it must be from the clerk of the county in which the applicant resides. If there be a change of residence, however, a new license must be obtained. In case a diploma is not considered worthy of recognition, the applicant is given an opportunity to pass an examination."

While the Indiana decisions, illustrated in Article IV, requiring the physician to have a license in each county into which his practice extends, are superseded in that State by the new statute, they may still be regarded as authoritative precedents for the interpretation of statutes in sister States similar to the one which they construed.

Pith of Current Literature.

Rebreathed Air as a Poison per se.—Dr. John Hartley (*Lancet*, September 17, 1898; *Journal of Laryngology, Rhinology, and Otology*, April, 1899) says that the modern treatment of phthisis is made up of three essential factors: 1. The discontinuance of the supply of bacilli from without. 2. The abundance of nutritive material for the tissues. 3. The supply of an abundance of fresh air uncontaminated by the products of respiration. This seems to mean that the tissues, if not too enfeebled, may be trusted to deal with the bacilli already present if their metabolism is kept going at high pressure. Rebreathed air and sewer gas should not be looked upon as mere carriers of accidental poisons, but as poisons *per se*. Hence the writer enters a strong plea for thorough ventilation—a different thing from the small trickle of air supplied by the tiny "ventilators" which are so hopelessly inadequate.

Pieric Acid in Membranous Enterocolitis.—The *Revista de Anatomia patológica y Clínica* for February 1st and 15th, citing the *Gaceta medico Catalana*, recommends that in the morning, before breaking fast, a quart of borated water should be used for a lavage, to remove accumulated matter and to dislodge from the intestinal wall the adherent membranous concretions. After the bowels have moved, a quart injection containing a teaspoonful of the following fluid should be injected:

R Pieric acid 15 grains;
Distilled water 180 "

M.

This last injection should be retained. The pieric acid used in this way directly antagonizes the lesion, quickly modifying the altered epithelium.

The Incubation Period of Measles.—Dr. James C. Wilson (*Dunglison's College and Clinical Record*, March 15th), lecturing on a case of typhoid fever, said that the most interesting thing about the case was that the patient stated that he was placed in an ambulance with a man suffering with measles, which he himself had never had. As a result he got another infection which ran its course independently of the fever. It was generally difficult, said Dr. Wilson, to fix definitely the period of incubation in these infective diseases, but here was a case in which the time of exposure was definitely known. On the thirteenth day after exposure the first symptoms of measles were noticed, and on the fifth day following the rash appeared, or eighteen days after the first exposure. In the text-books the time was variously stated at from seven to fifteen days; this case, taking the weakened condition of the patient into consideration, pointed to the longer period as being the more likely. As to the character of the rash, it was his belief that the character of the skin determined its intensity rather than the severity of the disease; in cases where the skin was of a sensitive, easily irritated nature the eruption was more marked than in less susceptible integuments.

The Transplantation of Nerves.—Dr. Reuben Peterson (*American Journal of the Medical Sciences*, April) thus concludes an inaugural thesis read before the Chicago Academy of Medicine:

"1. Transplantation of a peripheral nerve segment to bridge over a gap between the two ends of a resected

nerve is a legitimate surgical procedure. 2. Under favorable conditions at least partial, and at times complete, restoration of sensation and motion may be expected to follow the operation. 3. Regeneration of the degenerated peripheral end is due to down-growths from the axis cylinders of the central end. 4. From the slowness of this process the longer the time after operation the more favorable will be the results. 5. Sensation may return very early after operation, and, as a rule, precedes return of motion. 6. This rapid return of sensation is not due to down-growth of axis cylinders or to conductivity of the transplanted fragment, but must be explained by collateral nerve supply. 7. In many cases very early return of motion after transplantation may be due to vicarious movements of other muscles than those formerly paralyzed and not to a regeneration of the latter's nerve supply."

A New Suture for the Intestines.—Barker (*British Medical Journal*, July 16, 1898; *American Journal of the Medical Sciences*, April) describes a new self-feeding needle and holder with which he is able to place in the intestine with an ordinary fine sewing-machine needle a suture that is like the sewing of a machine. It is, however, capable of introducing any form of stitch desired. The handle of the needle holder carries three reels of thread and holds the needle in any desired position. In introducing the sewing-machine stitch the following method is employed: The needle is passed through the tissue and the loose end caught and drawn out a little longer than the length of the wound. The needle is then passed a second time and withdrawn slightly, leaving a loop; the loose end of the thread is passed through this and drawn tight and at the same time the needle is withdrawn and its thread tightened. The same process is carried out with each stitch to the end, where the final stitch is tied. This saves all the time and trouble of tying the sutures, with the exception of the last. The self-threading needle the author does not claim to be new, but the stitch he believes to be new and original.

The Improvement of Adenoids after Administration of Diphtheria Antitoxine.—Bécigneul (*Gazette médicale de Nantes*, January 1st; *Journal of Laryngology, Rhinology, and Otology*, April) relates the case of a child, aged seven years, with large pharyngeal adenoids, who was admitted to the hospital for a diphtheritic angina. An injection of Roux's serum was given. After culture the diagnosis made was staphylococcus angina; it was not due to Löffler's bacillus. After the serum injection the adenoids constantly diminished, and the child, who before the angina required operation, could easily breathe by the nose.

Heurtaux has tried in a case of adenoids in a child the same treatment (injection of ten cubic centimetres of antidiaphtheric serum). The result was successful; the adenoids disappeared in three weeks and the deafness was cured.

A Stethoscope for Use on Dependent Parts of the Chest. In the *Medical Record* for April 1st Dr. Andrew H. Smith remarks upon the difficulty of an culture the back of the chest in many cases in which the patient can not be moved from the dorsal decubitus without suffering. To meet this difficulty he has devised a stethoscope terminating in a shallow cup shaped like the cover of a pill box, the depth of which is less than half an inch. The rubber tubes are attached to the side

at points separated but a little distance from each other. The instrument is carried under the patient on the tips of two fingers, the thumb resting upon a projecting tongue which is continuous with the bottom of the cup, thus giving the necessary control.

With this instrument the auscultatory signs in the back of the lung can be obtained with scarcely any disturbance of the patient. Dr. Smith finds it convenient also in office practice, and especially in examining the heart in women, as it can readily be slipped down under the corset by simply unhooking the upper fastening of the latter.

The contrivance has some of the acoustic properties of the phonendoscope, and can be used with considerable satisfaction through several thicknesses of clothing.

Prolapse of the Urethra in a Young Girl.—M. Puech and M. Puig-Ametler (*Gazette des hôpitaux*, November 8, 1898; *Archives de médecine des enfants*, March, 1899) report the case of a young girl, six years of age, brought to the hospital with Pott's disease. For two years she had suffered from vulvovaginitis and urethritis of long continuance. For a month she had had vulvar pain and blood stains on her undergarment. In front of the labia minora, blocking the entrance to the vagina, was a tumor the size of half a nut with a widely dilated orifice in the middle. The tumor was soft and irreducible. On the introduction of a catheter, urine was withdrawn. It was evidently a prolapse of the urethral mucous membrane. M. Puech excised the tumor, and the child made an uneventful recovery.

Cosaprine, a New Antifebrile and Antirheumatic Remedy.—M. Vámosy and M. Fenyvessy (*Wiener klinisch-therapeutische Wochenschrift*, 1899, No. 2; *Presse médicale*, March 15th) have spoken highly of cosaprine, a sulphurous derivative of acetanilide, for its antifebrile and antirheumatic characters. It is a grayish-white powder, slightly salt in taste, odorless, and very soluble in water. Its reaction is slightly acid. M. Schudmak reports favorable results from its employment in sixty cases. In doses of from three grains and three quarters to seven grains and a half it notably lowers the temperature some hours after administration.

Its analgetic effect is less strong, but very certain. Its advantages over other similar preparations, especially in children, are stated to be its facility of administration, even in subcutaneous injections, its rapid action, and the total absence of secondary phenomena. So far neither cardiac, respiratory, nor sensory troubles have been noticed.

A Menstruating Man.—Dr. Rushton Parker (*British Medical Journal*; *Cincinnati Lancet-Clinic*, April 1st) records the case of a man, twenty-four years of age, who married a woman, but was unable to effect sexual intercourse with her. She noticed that he had a monthly sanguineous discharge lasting about three days and staining the linen. After eight months they consulted Dr. Parker. He describes the man as follows:

"I found nothing unusual in his general appearance, except a shy, cowed look, the penis, urinary meatus, and scrotum seemed normal, but the testes felt decidedly small and soft; he stated that he had never either abused himself or had any sexual feeling whatever. Being satisfied that he was at least not a complete man, and doubtless cowed by his wife's dissatisfaction, he readily consented to a separation and allowed her half his income."

Dr. Parker remarks on this case:

"It seems likely that this case differs from Ströbe's case of hermaphroditism, fully described in the epitome of the *British Medical Journal* for November 12, 1898, p. 79, merely in the fact that the rudimentary testes had descended into the scrotum, the man probably having also a uterus and Falloppian tubes."

Epilepsy and Epileptoid Manifested by Fright.—Professor Bejteref (*Obozrenie psijatrii*, December, 1898; *Revista de Ciencias medicas de Barcelona*, February 28th) has noticed in many cases of epilepsy attacks of fright, and says that such attacks are far from being rare in epilepsy. They may present themselves either in the form of an aura to attacks of *grand mal*, or as independent attacks alternating with the normal manifestations thereof. More rarely the fright phenomena constitute the principal manifestation of the epileptic neurosis, repeating themselves very often, being rarely replaced by ordinary seizures. The attacks of fright are not commonly accompanied by loss of consciousness or vertigo, but are very rebellious to treatment, or at least do not yield entirely to remedies ordinarily efficacious in epilepsy. Moreover, in the epileptoid seizures of progressive paralysis these terrors are at times observed, being distinguished from those which supervene in neurasthenia in that they do not show any connection with given external conditions, such as place, temperature, crowds, etc., as is the case in pathophobia.

The Tabetic Eye.—M. Gilles de la Tourette (*Journal des praticiens*, March 11th), in a recent communication to the *Société médicale des hôpitaux*, says that the ocular manifestations of tabes are numerous, since this disease affects the retina, the external muscles, and even the lacrymal passages. There is one symptom, however, which he does not remember to have seen noticed elsewhere. He has often, he says, seen to enter his consulting room a patient whose normal gait gave no suggestion of locomotor trouble, and at first glance has nevertheless marked him for a tabetic patient by the aspect of his eyes. It was not a question of meiosis, which, when punctiform and found in blue irides, suggests tabes, but a peculiar brilliant appearance of the eye, which, nevertheless, is expressionless.

This appears to the author to be a valuable early sign of the disease. It is independent of the condition of the pupils, which does not modify it, and is especially easy to note in those whose irides are dark in color.

Liquid Air as a Cautey.—According to the *Tri-State Medical Journal and Practitioner* for March, the use of liquid air as a cautey is already spoken of favorably. If having a temperature of 312° F. below zero, its action is, to all intents and purposes, the same as that of the most powerful actual cautey. It does not really burn, but utterly kills the tissues, leaving a blister not unlike a burn. Hence it has been suggested for cauterization in surgical practice. It is not only a good deal cheaper than the ordinary cautey, but it is much more efficient, and its action can be absolutely controlled. Indeed, a well-known surgeon has already performed a difficult operation on a cancer case with liquid air, and he has reported the case as cured.

Kernig's Sign in the Diagnosis of Meningitis.—According to the *Massachusetts Medical Journal* for March, Netter (*Bulletin médical*) calls attention to the sign given by Kernig, of St. Petersburg, for the diag-

nosis of meningitis, a sign not previously mentioned by physicians. Netter has found it in forty-one out of forty-six cases studied by him—i. e., in ninety per cent.

The patient is examined first in the dorsal decubitus and then sitting. In the first position it is very easy for the patient to extend the leg completely; in the sitting posture, however, the leg can no longer be extended completely. In very marked cases it can not be extended beyond ninety degrees, and in all cases not beyond a hundred and thirty-five or a hundred and forty degrees. But as soon as the patient lies down, complete extension is again easy. This phenomenon has not been met with outside of meningitis; no explanation is offered.

The Practice of Medicine in its Proper Light.—We quote the following from the *Clinical Reporter* for February: "What are we practising medicine for? Is our profession a business or a pastime?" These are questions put by *The Medical Examiner* in an editorial that appears in its current issue in defense of commercialism in medicine. "Is our profession a business or a pastime?" Neither, essentially, my lord! Our profession is "first, last, and all the time" a profession. Incidentally it may, in rare cases, be a pastime; it is, in most instances, a means of making a livelihood, and so far, incidentally, a business; but the relations which it establishes are relations of a peculiar personal trust on the part of the patient not only in the skill but also in the personal honor of the physician. It is this element of personal trust which, above all, distinguishes a profession from a mere business, and which forbids all devious methods, all commercial systems of offering or receiving commissions from other professional men, specialists, etc., for cases referred. It will be a sorry day for the medical profession when the majority of its members will look upon it as primarily a business—a sorer day for their patients!

The Parasitic Fungus of Cancer.—M. Bra has for nearly four years been prosecuting researches into the nature of cancer. These researches are given in full in the *Presse médicale* for February 22d, and we here give an abstract of them accompanied by reproductions of the original illustrations.

In cultures from a great number of different kinds of neoplasms, including carcinoma of the ovary, epithelioma of the tongue, carcinoma of the breast, sarcoma of the maxilla, carcinoma of the parotid, epithelioma of the cervix uteri, carcinoma of the body of the uterus, and cancer of the rectum, Bra has succeeded in regularly isolating a fungus apparently belonging to the *Ascomycetes*.

The Isolation of the Parasite.—This may be effected in two ways—viz., by fragmentation of the cancerous tissue and by bleeding, of which the former method is preferred. The tumor, freshly obtained, is submerged in a two-and-a-half-per-cent. carbolic-acid solution, then placed upon a plate sterilized by heat. The cancerous nodules are isolated and divided into small cubes of about three fifths of an inch, which are plunged into sulphuric ether and passed rapidly on a needle point through a flame. They are then sown in test tubes or small flasks containing bouillon of cow's udder, which are placed in an incubator at from 86° to 95° F. The tubes should not be opened for from fifteen to twenty days, at which period the culture frequently contains, independently of the infinitely small

spores that may be taken for bacteria, some adult and very characteristic forms. When these last are well developed, the cancerous fragment at the bottom of the vessel and the "magma" formed around it present a clear, rose tint, the bouillon is slightly turbid and also rose-colored, and on its surface appears a pellicle of a grayish-white tinge above, and flesh-colored beneath. This culture serves for the sowing of other tubes of bouillon, but in order to observe the parasite in its most

metres or more. They have a great tendency to agglomeration, being united by a colloidal substance which they secrete. They possess a central plasmic mass and an enveloping membrane of single or double contour, which does not stain (Fig. 1). Before sporulation the central plasma is homogeneous and stains uniformly. These spherules are reproduced endogenously by spores which make their exit from all points of the cell, and are expelled in the midst of a gelatinous agglutinating ma-

perfect development it should be transplanted to agar. An infinite series of cultures may be obtained, but it is best not to resow oftener than every twelve or twenty days.

The second method is by collecting some drops of the patient's blood with a sterilized pipette, either from the periphery of the tumor or by a prick of the finger. These are then sown in a tube of bouillon. In favorable cases a culture is developed in from ten to fifteen days. It is by no means the case that blood taken from the general circulation regularly gives cultures. As might be expected, the probability is in proportion to the infection of the patient. They are often

FIG. 2.—Culture of the parasite on agar. (Zeiss objective, immersion; ocular 1. Karmansky del.)

fertile, however, when the patient presents the characteristic pale-yellow carcinoma.

Morphology.—The parasite is found in the form of spherules and of cylindrical cells. The spherules are refractive, of a clear, yellow green color. They are rounded, ovoid, or polyedral. Their mean diameter is one micromillimetres, but they may reach twelve micromil-

terial, the spherule, when empty, becoming a mere honeycombed envelope. The inequality of sporulation and of the growth of spores produces on the surface of the spherule strange forms, linear, punctiform, reniform, falciform, etc. (Figs. 2 and 5), and impresses on them the varied aspects which have been described by the partisans of parasitic doctrines, and which have given rise to a belief in the existence of falciform bodies, the growing stage of coecidia, etc.

The smaller spores of about one micromillimetre display Brownian movements. They are ruby red, round, and unicellular, or of bacillary form, cylindrical and bicellular (Figs. 3 and 4). In the latter case they have

FIG. 4.—Culture of the parasite on agar. (Zeiss objective, immersion; ocular 1. Karmansky del.)

the appearance of encapsulated bacteria. The cylindrical cellulae, or coecidia, measure, on an average, in their greater diameter, from one to two micromil-, transversely two micromillimetres. They are refractive, almost cylindrical, and are covered with a thin, transparent, and fine granular envelope. They have a great tendency to agglomeration, and, or to

group themselves in concentric circles. They put forth germinal processes at their extremities. These hyphae are so irregularly divided that the author for a long time thought them to be exclusively unicellular. They

Mycelium giving rise, both at the extremities and in continuity, to rounded conidia. 2. Culture upon bouillon of dried grapes. Mycelium in bundles with rounded conidia. 3. Culture on agar glucose. Spherules in a state of sporulation and dead spherules. Cylindrical, irregularly cylindrical, fusiform, and curved elements, rods, etc. This figure includes many parasite forms described by the partisans of the coccidian theory. 4. Culture in udder broth. Spores and spherules. These spheroidal elements of all dimensions correspond to the fuchsin bodies of Russell. 5. Culture upon agar agar.

are from one to two micromillimetres in diameter, and their length is not limited. They remain simple, and frequently branch, giving rise at their extremity or at the extremity of their branches to round, oblong, or elliptical coccidia. Sometimes the coccidia occur in file inside the spore-bearing filaments (Figs. 4 and 5).

Cultures of spherules free from cylindrical coccidia and mycelium filaments, and *vice versa*, may be obtained. But these forms, on being transferred from one medium to another, or as the medium grows old, are transformed one into the other. We have to deal, therefore, with two different forms of one parasite, and not with a symbiosis. In the membranes formed by the fungus on the surface of cultures, the germinal tubes sometimes remain as free hyphae, as filaments loose or irregularly interlaced; at other times they unite with one another to form homogeneous bundles cream coloring the interstitial spaces and being of different size and shape, containing mass of spherule in a state of activity or of death, bundles and mass which constitute an often extremely resistant pseudoparenchyma. *Pertidocoma* and *alaba* be formed.

The Staining, Bological Characters, and Cultures

of the Parasite.—The spherules and the coccidia are visible without staining. They are colored by watery alcoholic solutions of aniline dyes, especially by Kühne's blue. They take Gram, which allows of their being distinguished in the blood and the tissues. They may be stained by hematoxylin, gentian violet, and safranin. Picrocarmin sometimes stains them red and sometimes yellow.

The fungus is aerobic. It may be cultivated at the laboratory temperature, but the cultures are more prosperous at from 86° to 95° F. The spores resist, however, for half an hour at least the temperature of the autoclave. The parasite undergoes desiccation, in the course of a year, at the temperature of the laboratory. A stay of several months in water does not cause it to lose its power of vegetation. Carbonic acid under a pressure of sixty atmospheres for six hours does not kill the spores.

Udder broth is the best medium. It is prepared with cow's udder in the same manner as simple bouillon, with the single addition of about two to a thousand of chloride of sodium. It is neutral to turmeric. From about the fifth to the eighth day there forms on the surface of the liquid a whitish-gray pellicle, and a sedi-

Fendel as found in cancer of the rectum, *Annals de micrographie*, 1894, vol. ix, pl. II. 2. Pseudo-coccidia, Russell's type, after Noegwirth, *ibid.* n. Fig. 50, 51, 52. 3. Parasites of cancer, after Sondakewitch, *pl. vii, fig. 1, Ann. Inst. Pasteur*, 1892, No. 8, pp. 545, 557. 3', Sondakewitch, Same collection, 1892. 4. Sondakewitch, *Ibid.*, 1892, No. 3, pp. 115, 117, pl. VI. 5. Bionchi, *Arch. de phys.*, 1894, series, vol. x, taken from Fig. 24 and 25, pl. V. 6. Parasites of cancer after Podyscholski and Savitschenko, *I. 1895, vii and viii, Figs. 23, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.*

ment of the same color falls to the bottom. The cultures are more abundant when ten per cent. of glucose is added to the broth. In sterilized milk they form grayish white membranes adherent to the test tube. In agar,

from the third day, round, grayish-white colonies form, which liquefy in about ten days. The agar becomes colored brown throughout. In serum they have the same characters as on agar. Gelatin liquefies and a grayish-

FIG. 7.—Blood taken from the vicinity of the tumor in a cachectic subject of cancer of the breast and uterine fibroma (Zeiss objective, immersion, ocular 1, after Karmansky). The parasite is seen in the form of free spores of various sizes. A little above, and to the right of the centre of the preparation are two cylindrical rods.

white pellicle forms on its surface. On potato, a viscid, grayish-yellow layer forms. After some time all these cultures lose their normal tint and take on a fine rose color, due to the dissemination of the ruby-red spores into the medium.

The Parasite in Cancers.—In cancerous tumors the fungus presents the same forms, spherular or cylindrical, as in cultures. These parasites, the author says, have been noted, but mistaken for coccidia by many observers; while they have been interpreted by the histologists as anatomical elements allied by insensible gradations to the neoplastic cells from which they have been held to be only degeneration products. Figs. 5 and 6 show the elements observed by the histologists in comparison with the parasites grown in the cultures, thus displaying their probable identity. These parasites, however, exist in large numbers in malignant tumors, occupying extracellular, intracellular, or intramammary positions, or simulating the cellulæ with its nuclei or nucleoli. But if the round and cylindrical forms of the fungus have been seen, even though wrongly interpreted, by other observers, the existence of a mycelium in cancerous tumors has not hitherto been suspected, excepting, perhaps, by Soudakewitch, who has described "a kind of spores borne on long filamentous" such as are accurately reproduced in Fig. 6, 37.

The fungi are found in the blood either in the activity of the tumor or in the general circulation. They should be examined in the fresh state without drying, or in the dry state by Gram's method, and counterstained with safranin. The parasites are colored violet, and the blood corpuscles rose colored.

Experimental Tumors and Infection.—Bra has injected intravenously one cubic centimetre of virulent broth culture into rabbits—the animals died of subacute mycosis from the fourth to the fifth day; in twenty-four hours when inoculated with two, and in sixteen hours with three cubic centimetres. Multiple lesions were found. In some cases rabbits previously submitted to subcutaneous injection of very small but increasing doses of the culture resisted subsequently the intravenous injection of a fatal dose. Inoculation of the culture into the breasts of animals, or its subcutaneous inoculation, produced formation *in situ* of tumors of the size of an olive, and tending to increase in volume. In some cases the skin became thin, and subsequently perforated, and gave vent to a thick, grayish-white fluid consisting of cellular detritus, spores, and sporules. In other cases small persistent cysts were formed, whose walls in thirty per cent. of the cases became thickened, filling the central cavity and giving rise in four or five months to hard, irregular tumors of the appearance and consistence of fibro-sarcomata (Fig. 8), which were infected with parasites, as in fibro-sarcomata of human beings. Portions of the tumors, being again sown in under broth, gave cultures of the parasite. Two or three months after inoculation extreme cachexia ensued, and dermatitis, gastric ulcer, glossitis, or hypertrophic cirrhosis appeared. No noticeable results were obtained in guinea-pigs. In bitches injection into the mamilla produced tumors sometimes ending in resolution, but sometimes augmenting and possessing the appearance of fibro-sarcomata and typical cancer. Dogs inoculated,

FIG. 8.—Fibrous tumor developed in the abdominal region of a rabbit, inoculated with the culture of the parasite. The structure is that of a fibrous tumor, and when seen under a microscope, it resembles a sarcoma.

although showing no local reaction, died in some months because emaciated, and the appearance of visceral tumors, apparently of the same nature. Subsequently to the death of the animal, the tumor info-

animals, Bra has observed a complete gradation from acute or chronic inflammation and sclerosis up to fibrosarcoma and cancer.

To sum up: 1. By inoculating animals with pure cultures of a fungus obtained from human cancer Bra

FIG. 9.—Carcinoma of the breast in a bitch inoculated six months previously ($\times 250$, after Karmansky).

professes to have caused them to develop tumors possessing indifferently the structure of typical cancer and fibrosarcoma.

2. These tumors, being sown themselves, have regularly produced pure cultures of the parasite like those obtained from human tumors.

Book Notices.

The Principles and Practice of Hydrotherapy. A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. By SIMON BARUCH, M. D., Visiting Physician to the J. Hood Wright Memorial (formerly Manhattan General) Hospital, etc. With Numerous Illustrations. New York: William Wood and Company, 1898. Pp. vii+155.

THE debt under which we all, as physicians, rest to Dr. Baruch for his long-continued efforts in behalf of intelligent hydrotherapy has become greater with the appearance of the work now before us. For readers in English such a work has long been a great necessity, and it is a matter of satisfaction to us that the need has at last been supplied and by one whose fitness for the work is unquestioned. Enthusiastic in many ways the work is, but not to an unwarranted degree, for threaded out there are maintained a reasonable part and a balance which are none too often perceptible where a special form of therapeutics is the theme.

Two parts constitute the work. The first treats of the physiology of water applications, while the second discusses their therapeutics. In one respect we are disappointed, for, while hydrotherapy, as the author himself points out, includes the internal use of water as well as the external, the former receives but scant notice. This is to be regretted, but after all it is not unnatural, for indeed the newer hydrotherapeutics is concerned chiefly with water in its external application. Of these applications the presentation is in every way satisfying and complete, while the very practical quality of the chapters, whether they are descriptive of apparatus and technics or of clinical applications, is to be noted and admired.

Naturally the *pièce de résistance* is the full cold bath, and, while this, thanks largely to Dr. Baruch's efforts, is now a matter with which most of us are familiar, nothing but good can come from its continued discussion. The prominence given to it does not signify a neglect of other measures. The chapter upon irrigation is noteworthy for completeness and the inclusion of a number of very recent observations, especially as concerns enterocolysis.

Of the diseases in which the water treatment is so valuable, typhoid fever will probably ever be the field for the most brilliant results, and this from its very nature and the important part nerve invigoration plays in its course. The chapter upon pneumonia, however, is little less interesting and valuable, as are also those upon enterocolitis and cholera. Insolation is discussed to our great satisfaction and particularly from the fact made prominent by the author that cutaneous stimulation (by affusion) is essential if good results are to be expected, a matter to which we have before alluded. The book is valuable in an unusual degree, and its faults are few and inconspicuous.

The Dawn of Reason, or Mental Traits in the Lower Animals. By JAMES WEIR, JR., M. D. New York and London: The Macmillan Company, 1899. Pp. xiii+234. [Price, \$1.25.]

IN this little volume the author devotes his time to a somewhat elaborate description of animal traits. His object is to show that these so-called psychological characteristics indicate that the lower animals' mental organs, if the term can be thus rightly applied, are the same in kind as those of man. The subject of necessity involves much technical phraseology and the use of abstract terms pertaining to nice points of distinction, such as the differences between instinct and reason.

As a contribution to the broad study of biology, considerable of interest has been adduced and some points involving original research are recounted. But we doubt whether much of real value has been presented relative to the study of comparative psychology other than an accentuation of the fact that from the amoeba to man there exists a certain degree of consciousness and so-called "general intelligence." As another writer on the subject has it, "The turning point in this endless and uninterrupted process of evolution, the point at which the beast ceases and man begins, is where the soul is no longer the mental, but asserts its supremacy as the master of the body."

Assuming that this point is where true reason might have its origin, we do not so clearly follow the argument for an earlier dawn. As a matter of fact, the question is, more or less, one of definition. The volume is not

without interest and, as compared with a previous effort of the author's, is more to be recommended.

The Living Organism. An Introduction to the Problems of Biology. By ALFRED EARL, M. A., Late Scholar of Christ's College, Cambridge, etc. London and New York: The Macmillan Company, 1898. Pp. xiii+271. [Price, \$1.75.]

It may be assumed, to begin with, that there is great need of elementary training in the field of biological research. It is obvious that a fault in the premises produces far-reaching error, and much of the disrespect with which the world receives physiological and psychological results is due to a lack of confidence in the methods. We should all be intensely interested in much that comes from the laboratory did we believe that a truly philosophic spirit and a scientific instinct were behind it.

On the other hand, progress in biological research is made by comparatively few investigators, those whose lifelong training has been given to it; a few others help, the greater number merely trouble the stream with loose speculation and conjecture. To these latter we fear such a book as Mr. Earl's will not be adapted, in spite of their need of it; but its influence would be excellent.

Degeneracy: its Causes, Signs, and Results. By ERGENE S. TALBOT, M. D., D. D. S., Fellow of the Chicago Academy of Medicine, etc. With One Hundred and Twenty Illustrations. London: Walter Scott, 1898. Pp. xvi+372. [Price, 6s.]

THE author, who has, according to the preface, been engaged for more than twenty years in "a limited medical department of biology," dentistry, says that the truth of the degeneracy doctrine had forced itself upon him long before its popular apotheosis under Lombroso and Nordau.

The results of his observations and extensive reading have furnished material which he hopes will be of use to parents and educators. With this idea in mind, he has avoided extremes, and has attempted, as he says, to lay down general principles for practical purposes in a way that permits of their application to the solution of sociological problems.

The book deals with the stigmata of degeneration somewhat extensively, and it is probable that the average "parent and educator" will have a bad quarter of an hour when he begins to examine himself or his charges in the light of this information, but the result will in many cases be helpful. We doubt, however, whether the portions of the book dealing with still unsettled points of brain physiology and matter of a special or statistical nature will be of value to the non-medical public.

A book on the same lines, with the descriptions and pictures of the extreme types of degeneration and their anatomy omitted, but with more stress laid on the commonplace signs and causes of nervous fatigue in modern life, and especially in childhood, and their prevention, would be of much use to the public. Such books exist, but they represent the two extremes, and each extreme is in danger of exciting only a morbid or sensational interest in the mind of the average reader. We might almost add the thrust for this class of books to be by the non-professional reader to the ever increasing list of stigmata.

As this book is not especially intended for the medical profession, it is fair to criticise it only in general terms. The author has made numerous and, for the most part, well-chosen quotations, but a more careful use of quotation marks would seem to be desirable.

On the whole, the book is well written and interesting. It shows enthusiasm if not optimism, industry, and, in the author's own field, an excellent power of observation.

Examination of Water. (Chemical and Bacteriological.) By WILLIAM P. MASON, Professor of Chemistry, Reims-solier Polytechnic Institute, etc. First Edition. First Thousand. New York: John Wiley & Sons, 1899. Pp. 135.

A MORE practical manual on water examination it would be difficult to imagine, and the work has that great quality, too, of simplicity and easy comprehensibility which in matters scientific is so unnecessarily rare. Brevity, moreover, is a prominent trait, and yet it is not insufficiency in any sense, though the subject has not been exhausted, but rather shown forth in its essentials.

The major part of the volume is devoted to chemical analysis, and so well expressed is the matter that the physician may derive little less than the chemist from its perusal. The smaller part is on bacteriological analysis. Enough, however, is here set forth to give one a comprehensive idea of the bacteriology of water used for domestic purposes without poaching upon the intricacies and refinements of the subject which necessarily pertain to the bacteriologist.

The book gives one a very excellent survey of its field and is warmly to be commended.

Fever-nursing: Designed for the Use of Professional and Other Nurses, and especially as a Text-book for Nurses in Training. By J. C. WILSON, A. M., M. D., Visiting Physician to the Hospital of the Jefferson Medical College and the Pennsylvania Hospital, etc. Third Edition, revised and enlarged. Philadelphia: J. B. Lippincott Company, 1899. Pp. 3 to 241. [Price, \$1.]

THE third edition of this excellent little work presents the admirable features of its predecessors, together with the additional considerations which medical progress has required. Of these, the most conspicuous are in the subjects of serum treatment and disinfection. Noteworthy, too, are observations upon the nursing of soldiers ill with febrile diseases, in camp as well as in transportation.

The book can scarcely fail to be useful and helpful to those for whom it was written. Particularly noticeable and of the greatest value is the simple, comprehensible, and interesting style in which it is written.

A Compend of Human Physiology. Fully and Adapted for the Use of Medical Students. By AUGUST F. BRUNNEN, A. M., M. D., A. O. Professor of Physiology and Hygiene, University of Pennsylvania Medical College, etc. Ninth Edition, revised and enlarged. With New Illustrations and Tables of Physiological Constants. Philadelphia: P. B. Blakely Son & Co., 1899. Pp. viii+260. [Price, 80c.]

THE fact that this book has been so ready in its ninth edition, speaks well for its merit. The text has been revised and enlarged in a convenient

table of physiological constants has been added. As in previous issues, the treatment of the subject is clear and concise, and the whole field of physiology has been gone over in a way which, for a book of its kind, leaves very little to be desired.

BOOKS, ETC., RECEIVED.

Nervous and Mental Diseases. By Archibald Church, M. D., Professor of Clinical Neurology and of Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School (the Chicago Medical College), Chicago, etc.; and Frederick Peterson, M. D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York, etc. With Three Hundred and Five Illustrations. Philadelphia: W. B. Saunders. 1899. Pp. 11 to 843. [Price, \$5.]

Albuminuria and Bright's Disease. By Nestor Tirard, M. D., F. R. C. P., Physician to King's College Hospital and Senior Physician to the Evelina Hospital for Sick Children, London, etc. With Original Illustrations. London: Smith, Elder, & Co., New York: G. P. Putnam's Sons, 1899. Pp. 362. [Price, \$5.]

An Essay on the Nature and the Consequences of Anomalies of Refraction. By F. C. Donders, M. D., Late Professor of Physiology and Ophthalmology in the University of Utrecht. Revised and edited by Charles A. Oliver, A. M., M. D. (Univ. Pa.), one of the Ophthalmic Surgeons to the Philadelphia Hospital, etc. With Portrait and other Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. viii-9 to 81. [Price, \$1.25.]

The Pathology and Treatment of Sexual Impotence. By Victor G. Vecki, M. D. From the Author's Second German Edition, revised and rewritten. Philadelphia: W. B. Saunders, 1899. Pp. 11 to 291. [Price, \$2.]

Les régénérations d'organes. Par le Dr. Paul Carnot, Docteur es sciences, etc. Avec 16 figures dans le texte. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 96. [Price, 1 fr. 50.]

Transactions of the Medical Society of City Hospital Alumni. For the Year 1898. St. Louis.

Seventh Biennial Report of the North Carolina Board of Health. 1897 to 1898.

Unguentum Hydrargyri or Blue Ointment Administered by the Mouth. By Albert Bernheim, M. D., of Philadelphia. Read before the Mississippi Valley Medical Association, October, 1898.

The Diagnosis of Early Pregnancy. By Albert Bernheim, M. D. [Reprinted from the *American Practitioner and News*.]

Small-pox and Vaccination. By Albert Bernheim, M. D. [Reprinted from the *American Practitioner and News*.]

Correspondence between a Layman and a Surgeon on the Subject of Appendicitis. By Robert T. Morris, M. D. [Reprinted from the *Medical Record*.]

Genital Neuralgia and Genito-reflex Pains. By Frederick Porter Hammond, M. D. [Reprinted from the *Philadelphia Medical Journal*.]

The Etiology of Seasickness. By William Edgar Darnall, M. D., of Atlantic City, N. J. [Reprinted from the *Journal of the American Medical Association*.]

The Dietion of Amylaceous Food. By Robert W. Hastings, M. D., of Brooklyn, Massachusetts. [Reprinted from the *Annals of Gynecology and Pediatrics*.]

A Peculiar Epileptical Case of the Cerebellum, and some Remarks concerning the Neuroglia. By Dr. E. J.

Mellish and Dr. Maximilian Herzog, of Chicago. [Reprinted from the *Chicago Medical Recorder*.]

Ueber breite Amputation mit nachfolgender Autoplastik bei Brustkrebs. Von Professor Dr. Assaky in Bukarest. [Separatdruck aus der *Münchener medizinische Wochenschrift*.]

New Inventions, etc.

FOSTER'S MODIFICATION OF THE HAGEDORN NEEDLE.

By WILLIAM DAVIS FOSTER, M. D.,
KANSAS CITY, MISSOURI.

The advantages alleged for this new kind of needle (Hagedorn) are:

1. Being curved on the edge, they are more resistant, and the point follows without deviation the intended direction of the puncture.

2. The eye, perforating the flat side, can be made larger and tapering at the terminal end; in consequence of which, even a stout double thread will pass without difficulty through the puncture, which no surgeon will fail to appreciate.

3. The needle, owing to its equal thickness, can be firmly and safely taken hold of at any point, whereby its direction will be much facilitated.

4. The cutting edge, being on the convex side, can not be injured or blunted by the needle-holder and may be easily resharpened by the surgeon himself.

5. The incisions of the old cross-edged needles spread, while the incision made by the new needle is in a right angle to the edge of the wound, similar to a buttonhole. The two edges of the stitch wound, on tying the sutures, are drawn into close apposition, whereby their union is favored.

6. The flat needles cause less injury, which is of high importance, especially in sutures of nerves and tendons.

The practical surgeon will note that the use of the

Hagedorn needle requires a specially made needle-holder. It may not always be convenient to carry this needle-holder in the surgical bag. I have, at the suggestion of the Rev. Dr. J. Stewart Smith, of this city, had Tiemann & Co., New York, modify this needle so that it may be held by any needle holder or by a hæmostat.

Hagedorn Needle

FIG. 1.

The cuts, Figs. 1 and 2, will show a Hagedorn needle, and also the modifications referred to. The original specifications show that by making the needle *round* instead of *flat*, of the same weight of metal in the rest of the needle as at present, this modification does not in any sense impair the strength or peculiar cutting qualities of the needle. The heavily shaded part of the needle represents the *round part*.

Foster's Modification of the Hagedorn Needle.

FIG. 2.

If this improvement proves as useful to other surgeons as it has to myself I shall be abundantly repaid for any trouble that has attended its construction and illustration.

I am indebted to my friend Dr. J. C. Stewart, of this city, for the fine pen drawings from which the cuts are made.

Miscellany.

Lord Curzon on Western Medicine in India.—The *British Medical Journal* for March 11th devotes a column to some remarks of the Viceroy of India on this subject, and to appreciative comment thereon. As Lord Curzon has openly referred to the great assistance rendered by his American wife in his aims for the benefit especially of Indian women, the remarks have a special interest for us on this side of the water. The *Lancet* says: "The Viceroy of India said many graceful and true things about medical science in his speech at the annual meeting of the Countess of Dufferin's Indian Calcutta for giving medical aid to the women of India, on March 3d. After saying that the British had come to India as conquerors indeed, but as benefactors also, bringing religion, law, literature, and science into their hands; and after admitting that there were but two views about the three gifts first mentioned, the

said of science, and of medical science in particular: 'Now I come to the last boon, of science, and medical science in particular. About this no two opinions can possibly be entertained. There may be prejudices and scruples arising from long custom, ignorance, or other causes, but doubts there can not possibly be, and I say this, that if we had come back to you from the West with our medicine in our hand, and with that alone, we should have been justified in our return. For what is this medical science we bring to you? It is no mere collection of pragmatical experimental rules. It is built on the bedrock of pure, irrefutable science; it is a boon which is offered to all, rich and poor, Hindu and Mohammedan, woman and man. It lifts the *purdah* without irreverence. So far as I know, it is the only dissolvent which breaks down the barriers of caste without sacrilege. Medical science, indeed, is the most cosmopolitan of all sciences, because it embraces in its merciful appeal every suffering human being in the world. Now, our Anglo-Indian poet Kipling—I claim him as an Anglo-Indian, though he is also the property of the world—in his latest poem, and I hope and pray—and I am sure you join in that prayer—that it will be by no means his last, has thus written:

"Take up the White Man's burden—
The savage wars of peace,
Fill full the mouth of famine,
And bid the sickness cease."

Well, this part at any rate of the white man's burden, this portion of the bounty of the Aryans of the West, has not been ignored by the British in India, and in my view every hospital we build in this country, every doctor we train, every nurse we turn out, every patient we cure, is part of the service that we owe to India; is an element of our duty in this country; is part of the home-coming gift which the Aryans of the West have brought back to their kith and kin." The *British Medical Journal* remarks: "This tribute is as well conceived as it is generous, and we would venture to hope that Lord Curzon of Kedleston perceives the full significance of the words he uttered."

The Seventh Regiment, N. G. S. N. Y.—A well-deserved testimonial was lately presented to Dr. Daniel M. Stimson on his completion of twenty years' service. It was in the form of a gold medal, and it was intended as a token of the esteem in which Dr. Stimson is held, not only as a surgeon and an officer, but also as a man.

The Study of Pharmacy in India.—The *Pharmaceutical Review* for April says: "Much has been said and written about the necessity of taking up the white man's burden. No matter how poor or how good an opinion we may have of the motives that led to the adoption of this 'burden,' if we look at the ultimate result, we may not regret the fact that the Aryan Saxon race has acquired almost everywhere, and by some of her agents of evil action were doing, a bad name. Who would have thought, however, that the British would teach England a lesson in the study of pharmacy at the close of this century, a lesson which has not become known throughout the pharmacy of the world. We desire to call special attention to the study of what we should call a 'white man's burden' in western India. The college founded by the Government of Bombay, and the outbreak of the plague in the East. Other colleges have been founded, and the necessary amount allowed for the maintenance. More

than that, in order to secure students, thirteen scholarships are provided by various states. Where is there a state in Christendom that has done relatively as much for the advancement of pharmacy, where private munificence and legislative liberality have joined hands for the advancement of our calling? India is teaching the Christian Anglo-Saxon a lesson that we should do well to take to heart. What is more, this is but the beginning of an intellectual renaissance that seems to be in store for a people whose early civilization more and more excites our wonder and admiration."

Verses in Praise of a Physician.—The following verses, originally published in the *Westminster Gazette*, have been widely quoted, and were published in the *Lancet* for March 4th. They are by Mr. James Rhoades, a translator of the *Æneid*. The *Lancet* for March 25th republishes them with the subjoined Latin translation, in elegiac metre, by Dr. J. P. Steele, of Dublin:

TO A CERTAIN DOCTOR.

"I'm only a doctor," is your cry,

"Concerned with the body's ills and pains,
But witless of art and poesy.

And lost to the spirit's finer aims."

Ay, only a hand by hundreds blest,

A heart that has ach'd for all, save self,

A brain racked ever to find them rest,

A soul whose riches are scorn of self.

In vain we argue; the theme is old;

Some men love horses, some singing birds;

But e'en if the poet's song ring gold,

Shall deeds that are gold weigh less than words?

You waived the pleasure and wooed the strife,

Of thorns, not roses, have made your bed;

You longed for the lovely side of life,

And fought with the terrible instead—

Longed sore, but never had time to give,

"Till now it is all too late," you say.

So be it. Why, man, the life you live

Is one long poem from day to day.

[*Idem Latine Redditum.*]

MEDICO CUIDAM.

"Sum medicus tantum qui sanem vulnera læsi

"Corporis et morbos," care Machaon, ais;

"Quid nūhi cum Musis cui surdo cantat Homerus,

Cui profert cerco chelada signa Myron?"

Sed tamen est pergrata manus tua millibus ægris

In quibus es totus nec memor ipse tui;

Dumque feras aliis requiem tibi sæpe negatam,

Sæpe bonus rennis quas merearis opes.

Cur remoramur in his? sunt argumenta vetusta;

Nunc conipes, illum flens philomela juvat;

Aurea sint Sapphus lyra et aurea verba, Machaon,

Aurea sunt per te facta magis que valent.

Gaudia præteritis optasti tristia vite,

Promptior in spinis quam regulare rosas;

Dilexisti puer Aonidum nemus; arma Saluti-

Ca traque te retinent Hippocrate, enem;

Offa et Apele, dolles nunc prorsus ademptas,

Intercepe. Cane mentis et artis inops,

Sed quomodo læsa lacerare? Deini carminis instar

Est quantum vite canique, Machaon, agi!

J. P. S.

The January State Examinations.—We learn that 122 candidates were examined, of whom 94 were successful.

Julia's Incubator.—*Lyon médical* for March 19th remarks upon the habit among women of using the bosom—the space between the mammary glands—as a repository for various articles, letters, the watch, the purse, and the like. Our contemporary goes on to say that Julia, daughter of Augustus Cæsar, being pregnant, was desirous of giving birth to a son. In order to ascertain the sex of her unborn child, she carried an egg in her bosom. The augury was auspicious; a cock was hatched from the egg, and she bore her husband a son.

The New York City Medical Association.—An association having this name has recently been incorporated consisting of members residing in the various boroughs of the city.

White Men in the Tropics.—The *Army and Navy Journal* for April 8th says that in an article in the *Independent* Mr. Alfred Russel Wallace characterizes as a myth the current idea that white men can not live in good health in the tropics. The trouble is not with the climate, but with diseases resulting from insanitary conditions such as prevailed in Europe a century ago with the same result, and still prevail to a large extent in temperate zones. Mr. Wallace says: "Commonly associated with the tropics are the various forms of malarial fevers, but these also are in no sense due to the climate, but simply to ignorant dealing with the soil. My own experience has shown me that swamps and marshes near the equator are perfectly healthy so long as they are left nearly in a state of nature—that is, covered with a dense forest or other vegetation. It is when extensive marshy areas are cleared for cultivation, and for half the year are dried up by the tropical sun, that they become deadly. I have lived for months together in or close to tropical swamps, both in the Amazon Valley, in Borneo, and in the Moluccas, without a day's illness; but when living in open cultivated marshy districts I almost invariably had malarial fever, though I believe the worst types of these fevers are due to unwholesome food. But here again, malaria was equally prevalent in England less than two centuries ago.

"If we take the great belt about two thousand miles wide, extending from twelve to fifteen degrees north and south of the equator, we have an enormous area, by far the larger part of which is not only well adapted for European colonization in the true sense—that is, for permanent occupation by white men—but is, with proper sanitary precautions the most healthy and enjoyable part of the world, and that in which the laborer can obtain the maximum return with the minimum of toil.

"It is a well-known fact that in Ceylon and India the men who enjoy the best health are the enthusiastic sportsmen who seize every opportunity of getting away from civilization, and who often submit to much privation and fatigue, with benefit rather than injury to their health. The fact is that white men can live and work anywhere in the tropics, if they are obliged, and unless they are obliged they will not, as a rule, work even in the most temperate regions. Hence, wherever there are inferior races, the white men get these to work for them, and the kinds of work performed by these inferiors become *infra dig* for the white man. This is the real reason why the myth, as to white men not being able to work in the tropics, has been spread abroad."

Original Communications.

SYPHILIS AND THE LIVER.*

By J. G. ADAMI, M. A., M. D., F. R. S. E.,
PROFESSOR OF PATHOLOGY IN MCGILL UNIVERSITY, MONTREAL.

WITHOUT doubt the most important fact elucidated by a study of the hepatic lesions of syphilis is that, from an anatomical and histological point of view, no distinction can be drawn between secondary and tertiary syphilis.

Clinically, I admit that such a distinction is useful, nor do I wish it to be thought for a moment that I imagine it can be done away with, although even clinically—as seen in connection with the syphilodermia—the establishment of a hard-and-fast demarcation between what is secondary and what tertiary leads not infrequently to confusion. The most that can be laid down is that when syphilis is acquired in the ordinary way, by sexual connection, the extension of the disease in general follows a definite course, the tissues tending to be affected in definite order. Or perhaps it is more correct to say that in syphilis, as in other zymotic diseases—I use the term zymotic in its strict sense—there is a local or tissue predisposition, so that certain tissues are apt to be more extensively and more markedly affected than others, the virus multiplying more readily; so that in them, as a consequence, there is an earlier and more pronounced reaction.

But while this is the case, the reaction in a given tissue is of like order, be the period of local infection early or late; at most there may be histological differences caused by the age of the lesions and by variation in the interaction between virus and tissue. If the virus be strong, or the tissue be possessed of feeble reactive powers, the histological appearances differ to a greater or less extent from what is seen when the virus is weak or the tissue possesses originally or has acquired strong reactive power. And as a corollary to this, it may be said that where the virus is powerful and there is rapid proliferation there, in such diseases as syphilis and tuberculosis, the effects upon the tissues are modified so that we have to deal not solely or not in the main with the local disturbances caused by focal growth of the virus (infective granulomata), but see other well-marked anatomical changes, brought about by diffusion of the virus. In other words, where the tissues are susceptible and the virus relatively powerful there may be generalized tissue disturbances apart from, and in addition to, the granulomatous developments directly caused by the focal proliferation of the germs. For at the start it must be laid down that, although as yet we are uncertain as to the exact causative germ of the disease, syph-

lis is a disease of microbic origin. The more one studies, the more is one convinced that the analogy between tuberculosis and syphilis is complete—only in the one we have isolated and studied the germ, in the other we have not.

For what do we find with regard to the hepatic manifestations of syphilis? Let us first take those of the congenital disease. There are many reasons why these should be considered first: these were the first specific hepatic manifestations to be studied and clearly recognized; they are much more frequent and more extensive than are hepatic lesions in the disease of postnatal acquisition, and, death occurring very frequently within a month or two after birth, there is less uncertainty as to the period of development and duration of the lesions than there can be in the disease of adult life.

That the liver should be so frequently affected in this form of syphilis is easily understood if we remember that the specific syphilitic lesions of the newborn are congenital and not inherited, that the infection is through the placenta, and that, as a consequence, the infected blood coming from the placenta passes through the liver before it reaches the heart or any of the other tissues of the fetal organism. Chiari's well-known observation may here be repeated—namely, that in a hundred and forty-four cases of infantile syphilis he found the liver affected, and that extensively, in a hundred and twenty-three, or nearly nine tenths. In the adult, on the other hand, both brain and testicle are more frequently the seat of extensive lesions, and when it is remembered how relatively common is tertiary syphilis and how relatively uncommon specific disturbances of any of these three organs the contrast between the frequency of congenital and acquired hepatic disturbances become more manifest. At the same time I am not prepared to accept Fournier's statistics as perfectly reliable; careful observation of 3,429 cases of tertiary syphilis should surely reveal clinical evidence of more than nine cases of hepatic implication.

This is not the place for me to dwell upon the vulgar error of speaking of *inherited* instead of *congenital* syphilis; suffice it to say that Gartner's * *et hoc est absurdum* of the inheritance, so called, of paternal tuberculosis must hold equally for syphilis. Indeed, were it possible for the bacillus or germ of syphilis to be present in the ovum at the moment of fertilization, to lie latent during the embryonic period and only to cause reaction during fetal life, there is no reason why the different organs have assumed the form and size and time which will pertain to them, then, in the adult stage, even then such presence of the germ would not be true

* Fournier, *Précis de Médecine Syphilitique*, p. 10.

† By the late Dr. Fournier, it is stated that in 100 cases of tuberculosis probably the majority of the organs were affected, and that all are examples of such focal infection, and that the same is true of the disease itself.

* A contribution to the discussion upon syphilis at the New York Academy of Medicine, March 9, 1899.

inheritance—it would be an epiphenomenon; for true inheritance demands the carrying over of features peculiar to the germ plasma of the parents. The fortuitous inclusion of a microbe in one particular ovum is not a matter of inheritance.

The different forms of lesions due to syphilis to be met with in the infant's liver are, I think, included in the following list:

- I. Well-defined gummata.
- II. Miliary gummata with generalized fibroid change affecting circumscribed areas of the liver.
- III. Admixture of miliary gummata and generalized fibrosis affecting the whole organ, which is in consequence enlarged.

IV. Generalized atrophic cirrhosis without much evidence of gummata, but associated with icterus, œdema, etc., the organ being very granular and contracted.

Time forbids that I should quote examples of these different conditions. Quite the commonest is the second form, in which there are no well-developed gummata as generally understood, but on section through the affected areas numerous minute focal collections of small round cells are to be made out, invisible or just visible to the naked eye, and in their neighborhood extensive pericellular fibrosis, so that the organ presents a patchy appearance, paler areas of large size standing out against the darker red or liver-colored background of the unaffected tissue. Here we have to deal with a relatively early and progressive stage of disease in which there is little or no necrobiosis and development of gummy matter.

There are, however, fairly frequent cases on record of the development of true gummata, easily seen by the naked eye, some as large as an almond, recognized, not, I believe, in children born dead, but in those dying as early as two weeks after birth (Canton), and at times showing signs of contraction.

The relationship between these miliary gummata and the gross gummata of the liver is that between miliary tubercles and isolated caseous tubercles of the same organ. We never think of suggesting that the two latter forms of tubercle indicate different periods of the tuberculous process. At most we regard the first as of more acute, the second as of more chronic development. We know full well that miliary tuberculosis of the liver may develop at any stage of the disease, either soon after the primary infection or only as a terminal event after long years of slow and, it may be, intermittent extension of the disease elsewhere. The fact that both gross and miliary gummata may occur in the liver of the newly born is an absolute proof that the two forms are not characteristic of two different stages or periods of the disease—"absolute," that is to say, unless we are prepared to admit that while certain tissues, such as the skin, present well-marked secondary lesions, others may present either secondary or tertiary changes. If we do this, then the use of the terms becomes almost meaning-

less. For it must be kept clearly in mind that while the livers of these syphilitic infants show extensive fibrosis and indications which usually are recognized as of tertiary type, the cutaneous eruptions are of the nature of secondary manifestations.

But over and above the granulomatous changes in the infant's liver it is most noticeable that a more generalized affection is the characteristic feature—namely, fibrosis affecting either the whole organ or larger or smaller areas. Such fibrosis might be due to various causes; indeed, our knowledge of the ætiology of cirrhotic changes in the liver, as in the kidney, and our knowledge of fibrosis in general, is not sufficiently advanced to permit us to make positive statements. And yet, since 1896, when in this very room, although not before your society, it was my privilege to deliver the Middleton-Goldsmith Lectures,* and I discussed the pathology of fibrosis, some little advance has been made in our conception of the process. For, on the one hand, Flexner† has shown that toxic substances (the blood serum of another animal) may lead to the development of cirrhosis, and, on the other, Weaver,‡ of Chicago, within the last few weeks, working (I think I may say) along lines suggested by certain publications of mine, has demonstrated that bacteria exist which directly induce hepatic cirrhosis. Thus it would seem that whether in the process of excretion of toxic substances by the liver cells, or by the taking up of certain bacteria and the influence of their toxins when so taken up, the liver cells may undergo a parenchymatous degeneration so intense that death ensues, and following thereupon a replacement fibrosis occurs, more or less pure and unaccompanied by acute inflammatory change according as to whether the parenchymatous disturbance is unaccompanied by interstitial irritation or no. Where many miliary gummata are present much fibroid change is eventually brought about by the tissue changes which follow their development.

We are not as yet in a position to state whether the fibroid change of this type in the liver of the syphilitic child is a consequence of the attempted removal of the syphilitic germs from the portal circulation by the agency of the endothelium of the hepatic blood-vessels and by the liver cells, or whether it is purely the circulating toxins of the disease that cause the disturbance. To me it would seem that one or other of these causes must be at work. The pericellular character of the cirrhosis is against the change being in the main a fibrosis following upon round-celled and miliary gummatus infiltration, while the fact that the change may affect the whole organ, as again the very extent of the areas when the whole organ is not affected, is quite opposed to the view that we have to deal with primary focal

* *Medical Record*, 1896.

† Flexner. *Transactions of the Pathological Society*, Philadelphia, 1896.

‡ Weaver. *Philadelphia Medical Journal*, February 4, 1899, p. 283.

necroses, such as are to be met with in typhoid and other acute infective diseases, or in infarctous disturbances.

If Marchand's* cases of granular cirrhosis occurring in fetuses born dead are, as he holds, of syphilitic origin, they afford evidence of the extreme results of such fibrosis following upon generalized syphilitic parenchymatous hepatitis.†

Thus, to sum up the broad features characterizing the syphilitic manifestations in the infant's liver:

1. Syphilis may lead either to granulomatous deposits in the organ or to interstitial fibroid changes.

2. The specific granulomata may be present either in the form of minute multiple miliary gummata, or of isolated larger gummata, such as in general are regarded as being of tertiary nature.

3. It is not possible to regard the one form as secondary, the other as tertiary, for either may exist with cutaneous disturbances of the secondary type.

4. By analogy, the interstitial fibroid change, so common in infantile syphilis, would appear in the main to be secondary to a degeneration and necrosis of the hepatic parenchyma, induced by the action of the toxins of the syphilitic virus upon the individual liver cells. In part it is developed in direct association with the development of miliary gummata.

Passing now to the hepatic disturbances in syphilis of postnatal acquirement, we find it more difficult to determine the age and duration of the lesions found, a difficulty due to the fact that syphilis is not in itself a cause of death during the months which immediately follow infection. I know of no adequate study made upon the livers of those who, suffering from well-marked secondary symptoms, have succumbed to intercurrent disease or accident. A thorough investigation of the visceral changes occurring in the secondary period remains as much a desideratum to-day as it was in the seventies, when Jonathan Hutchinson called attention to this gap in our knowledge. It is, however, probable that in the vast majority of cases the liver is not gravely affected during this stage, for otherwise it is most unlikely that with the vast number of autopsies made annually a fair number of instances of death during this period should not have been investigated; so that any marked departures from the normal in the condition of the organ should by now have gained recognition. It is equally true that there might be a certain amount of disturbance—the existence of miliary gummata, or, again, of a moderate extent of parenchymatous degeneration—which might easily escape detection, or be ascribed to other causes.

Some few cases are on record of extensive hepatic derangement during the secondary state. Thus, Hilton

Fagge* reports the case of a female of twenty-three years in whom there was a history of syphilitic rash with loss of hair and macular syphilides; jaundice supervened and the patient became drowsy and comatose. At the autopsy, the liver, which weighed forty-six ounces, was of an opaque bright yellow color and of dense consistency. The surface was mottled, the left lobe resembling very closely that of the infantile syphilitic liver. On section the organ appeared pale and semipellucid, and macroscopically the parenchyma was seen to be replaced by connective tissue. Unfortunately, the description given does not extend to full details. But clearly here is a case of generalized cirrhotic change in secondary syphilis not unlike that found in the infantile disease.

Somewhat similar cases are recorded by Engel-Reimers,† Kratz,‡ and Neumann.§ In all these cases there was a condition not unlike subacute yellow atrophy. Engel-Reimers considered the condition due to enlarged lymph glands at the hilus. While these might cause icterus, it is difficult to see how they could bring about a general atrophic condition of the organ; the explanation is clearly inadequate. Neumann's case is distinctly interesting; it is that of a man of twenty years, ill for about eight months. When seen, in March, 1894, there were papules on the external genitalia and buccal mucosa, and a slight icterus. The jaundice became intense, with great abdominal pain and ecchymoses. The liver diminished, and in nineteen days the patient died with uræmic symptoms. To me the special interest lies in Kolisko's diagnosis at the autopsy, which was that of "catarrhal icterus with cholemia; regeneration of the hepatic parenchyma in the form of adenomatous tumors, following upon acute atrophy of the same." Here was evidently acute generalized hepatitis. According to Neumann, Dittrich collected forty-six cases of syphilitic hepatitis, and those in the main were from the secondary period of the disease. An observation by Bee|| would seem to indicate that such hepatitis, even when somewhat chronic, often leading to extensive trouble, may undergo complete absorption, or, at least, may be followed by no gummatus development.

It will be noticed that in the above cases jaundice manifested itself. Now jaundice is a not uncommon event in secondary syphilis. Attention has frequently been called to its existence from the time of Küssel and Gubler onward; Lancereaux alone collected twenty-one cases. Within the last two years Neumann, Joseph, and Uhlmann have redrafted attention to its prevalence. I can not but think that this group must

§ Neumann, *Monatsh. f. Med. u. Nat.*, vol. 1, p. 109, 1894. I am indebted to Neumann for the two cases of hepatitis.

|| Bee, *Gen. med. des. p.*, vol. 1, p. 188, 1888.

* Marchand, *Cellul. Pathol.*, vii, 1896, p. 272.

† Dr. Jacobs tells me that he has described one of the cases of atrophic cirrhosis in the infant, like Marchand, he was forced to conclude that it must have been of syphilitic origin.

afford another indication of what I have already dwelt upon in connection with infantile syphilis—namely, that the liver, being a great excretory organ, may in certain cases be so injured by the action of syphilitic toxins that parenchymatous and, it may be, catarrhal hepatitis is set up and the jaundice be an indication of the functional disturbances due to this cause. This view appears to be more probable than either of the other suggested explanations, which are that the jaundice is obstructive and due either to specific growths in the bile ducts, or to the pressure of enlarged lymph glands at the hilus of the liver upon the larger bile passages.*

We thus, even in the early stages of the disease of postnatal acquirement, obtain evidence pointing to the existence of generalized effects of syphilis upon the organ. As I have pointed out elsewhere,† a fairly extensive fibrosis, apparently independent of the gummatous developments, is not infrequently to be met with in cases where there is active progressive syphilis long years after primary infection.

Turning now to the more generally recognized evidence of syphilis affecting the liver in the tertiary stage—namely, the gummata—and discussing first the large gummata, which are the most characteristic lesions of acquired syphilis, it must be clearly borne in mind that two distinct conditions are popularly confounded together and both regarded as tertiary manifestations—namely, the fibroid pittings and cicatrices which are the final indications of gummatous deposits in the liver, which remain after complete absorption of the original gummatous mass. We not infrequently come across these disfigurements and distortions in the liver in the bodies of those who for years have presented no indications of active syphilis, and they must, I hold, be regarded as obsolete gummata. Indeed, in one case, upon making microscopic sections through a most characteristic puckering, I found scarce any fibroid tissue left; that also had undergone absorption. On the other hand, we have to recognize gummata with cheesy or gummy contents surrounded by fibrous tissue, which are latent or obsolescent, and others again presenting like characters, but surrounded by hepatic tissue, which under the microscope presents infiltration with small round cells and evidence of progressive syphilis. It is these latent and active gummata which alone are of any importance, for both indicate that the disease, to say the least, has not been eradicated from the system.

The important point to notice is that in one liver we at times meet with all the forms above mentioned. I have come across cases at autopsy showing well-walled cicatrices and puckering of practically obsolete gummata, large, well-defined gummata with necrosed centre, and, upon studying the sections of the liver from

the neighborhood of the latter, I have there seen the irregular minute collections of small round cells which, in an infant's liver, we would have had no hesitation in describing as miliary gummata. These appearances I have seen in the liver of a man dying apparently only between two and three years after primary infection, as again in the liver of another infected fourteen years before death.

The evidence before us all points to the fact that in the adult, as in the infant's liver, gummatous development may occur at any period after the disease has become generalized throughout the body.

From what has already been stated, it follows that the same lesions are to be met with in the adult liver as are recognizable in the organ affected by antenatal disease. There may be:

- I. Large well-formed gummata.
- II. Miliary gummata.
- III. Acute parenchymatous hepatitis (with jaundice).
- IV. Syphilitic cirrhosis.

But clearly the element of time introduces frequently a difference and appearances not seen in the infantile liver. Thus we encounter in addition:

V. Obsolescent gummata: large gummata undergoing involution and absorption, with surrounding and limiting fibroid change and contracture. This is the lesion most often met with, and most typical of the syphilitic liver of the adult.*

VI. Obsolete gummata, represented by puckering and deformity of the organ, with a relatively small amount of fibroid growth radiating from the seat of the previous gummatous formation—and by nothing else.

VII. A further lesion, which must be referred to here—one not seen in the infant †—is the development of tumorlike outgrowths, so sharply defined and so large as not infrequently to lead to the false diagnosis of malignancy. The structure of these masses affords ground for believing them to be the outcome of a slowly progressive centrifugal infection of the liver tissue from an original isolated gummatous focus (or small collection of neighboring specific tubercles), with associated reactive hyperplasia of the liver tissue at the periphery; progressive infiltration of the newly formed parenchyma by miliary gummata and eventual replacement of these last by fibrous connective tissue; so that microscopically these tumorlike outgrowths present an outer layer of liver tissue, infiltrated by collections of small cells, enclosing a dense mass of fibrous tissue with more or less "gummy" degeneration.

* What is the causation of the coarse bands of fibrous tissue radiating from these obsolescent gummata I must leave an open question. It has been suggested that they indicate a tendency for the fibroid change to be developed along the course of the main lymphatic vessels leading from the gummatous focus.

† In this I am mistaken. I owe to Dr. Jacobi (verbal communication) a reference to a case by Cohn (?) of one of these tumorlike formations in the infant presenting all the features here described.

* Neumann (*loc. cit.*) gives a full and interesting study of specific cicatrix.

† Adami, *Montreal Medical Journal*, xxvii, 1898, p. 112.

Time, therefore, is an element causing difference in the appearances of the adult and infantile lesions. But this is not the only one. The other, and yet more distinctive, is the predominance of generalized fibrosis in congenital syphilis, of focal granulosomatous changes in the syphilis of adults.

The explanation of this difference would seem to be that the young liver cell is more susceptible and less resistant to injuries inflicted by toxic substances; it is more prone to degenerate; and, if the view here enunciated be correct (namely, that the fibrosis is largely of the "replacement" type), we have in this feebleness of the young liver cell a sufficient explanation why fibrosis here predominates. With the adult cell it is different. Inasmuch as a main function of the liver is to eliminate toxic substances from the circulating blood, its cells with advancing life become capable of withstanding toxins to a relatively very considerable extent. It is, indeed, remarkable to observe what extreme degenerative changes of the cloudy and even of the fatty type may be observed in the liver cells of an adult rabbit—for example, a few hours after intravenous inoculation of a centimetre of a culture of such a form as the colon bacillus; and yet in the course of a few days (as determined in other rabbits similarly treated) the liver cells may have completely recovered and show no signs of the intense disturbance set up by flooding the system with the bacilli and their toxins.

Thus in the adult (as distinguished from the senile) there is not the tendency for the extreme fibroid change to manifest itself under the action of irritants, which in the young lead to the production of the same.

It may be asked why the liver of the newly born infant more than other organs is susceptible to these degenerative changes. There are, it seems to me, two main reasons: 1. The liver is especially concerned in elimination of toxic substances, and its cells bear the brunt of intoxication by the syphilitic virus. 2. Placed, as it is, between the placenta and the general circulation of the foetus, its cells tend to eliminate toxic materials brought by the umbilical vein; in this way, again, they bear the brunt of intoxication, and at the same time reduce the amount of toxic material capable of acting deleteriously on the other organs. But it must be remembered that other fetal organs may also show fibroid changes.

There is one other factor in the production of specific lesions which so far I have not touched upon, one which, judging from studies made, more especially upon the syphilitic heart and brain, may very possibly be of signal importance. I refer to arterial changes—arteritis and periarteritis. We know, however, practically nothing concerning the part played by this in hepatic lesions. I can therefore mention it and pass it by.

Hence, to sum up: While the changes seen in the adult and infantile syphilitic livers are etiologically and anatomically identical, they may present differences in

in part to their relative duration, in part to the reactive powers of the hepatic parenchyma at different life periods.

LOGICAL ANALYSIS IN THERAPEUTICS.*

By CHARLES E. QUIMBY, A. M., M. D.

THAT body of medical practitioners which claims preeminent right to the title "medical profession" and wears it as a distinctive badge separating its members from all schismatic sects and followers of false prophets, has boasted more loudly of, has clung with greater pertinacity to, and urged with more unfaltering earnestness no other evidence in support of such contention than that of strictly scientific methods in its investigations and in the clinical application of resulting deductions.

The justifying demonstration of this claim should certainly be found, if anywhere, in practical therapeutics. It is just here that the gauntlet has been thrown down by our rivals and the challenge accepted. It may not prove unprofitable, therefore, to consider how far our formulated methods of treatment, to say nothing of individual practice, justify us in claiming the victory.

There can be no question as to the superior scientific character of the principles upon which our therapeutic studies are based, and their results, assumedly, applied in practice. Disease, even with the recognition of specific aetiological factors, has, with us, long since ceased to be an entity, and pathic processes, with a few class exceptions, are now unquestioningly accepted in essence as normal systemic activities, which are simply called into play by irregular, intermittent forces instead of constant influences, but which, nevertheless, may be predicated just as certainly of defined causes as those labeled "physiological." Hand in hand with this transformation in our conception of disease came, as a logical necessity, the study of the physiological action of drugs, and then, supposedly, as an equally imperative consequent, the application of drugs clinically, not as specific agents neutralizing or nullifying disease *per se*, but as definite forces modifying, either positively or negatively, those subjective physical processes by which the system brings about restoration of normal conditions. It is just at this point, however, that practice seems in a measure to have failed to keep pace with precept. That this is so need not be surprising, nor should it be discouraging to the point of despair, for the emanation from an old and unquestioned faith in the presumably established curative power of definite drugs must of necessity be slow; and really so, inasmuch as properly holds to what he has, does not readily doubt of its value, until something else is proven to be better. And, too, we must admit, such old traditions as that of

* Read before the Society of Alumni of the University of Illinois, December 11, 1898.

our grandmothers that "garden celandine is good for jaundice" touch with surprising power the hidden superstitious faith which lurks in even the most scientific mind. But we are too far advanced in the era of scientific medicine to justify the retention of empirical methods, except in rare and isolated cases as unique exceptions, which by their very persistence add lustre to the scientific character of broad principles, and by their demonstrated value reveal the existence of still other therapeutic laws yet to be discovered and formulated. The accusation, however, of our antagonists that we are still wearing the elogs of empiricism, and that our vaunted science is largely tainted with the same toxine, can not be wholly denied, for the proofs are too obvious to admit of concealment.

The simplest and, for that very reason, the most conclusive evidence as to how far pure science dominates our clinical therapeutics is found in two distinct yet closely related conditions.

1. *The Permanency of Methods of Treatment.*—The ultimate conclusions of logical analysis should become established and permanent facts. If, therefore, our physiological and pathological data are true, the dependently deduced therapeutic laws should have a commensurate and permanent value, and the included clinical methods be subject only to relative but not absolute supersedures by products of similar logical analysis. A therapeutic agent should never lose a value once established for it by such scientific methods. Therefore, to set aside as valueless measures to which we have once attributed value is an unreserved confession that either our logic or our facts have been false—neither horn of which dilemma can be largely productive of pride or tortured into a compliment for our intellectual powers. When interrogating the facts, as revealed by prevailing methods of practice, to determine how far permanency of drugs justifies the idea that logical analysis dominates our therapeutics, one hardly needs to instance specific cases.

He who has watched for the past decade that jostling horde of barbaric drugs which, emerging from the sulphurous mists of the chemist's laboratory, have swept across the medical horizon in unbroken column, only to disappear in the silent caverns of oblivion, will hardly care to attack the statement that permanency is not the most obtrusive characteristic of prevailing methods of treatment. We can not refrain, however, from calling attention to the oft-quoted answer of the Edinburgh librarian when asked what medical books could best be packed away in the cellar, "Take anything that is over ten years old."

The same words have done yeoman service in illustrating the rapid advance of medical science, while their bitterly humiliating but none the less directly pertinent testimony to the transitory sway of therapeutic measures which have been boosted into power by personal dicta, only to fall from lack of scientific support, has

been ignored with painfully watchful care. To say more on this point were superfluous.

2. *Formulated Therapeutics.*—Unassailable and most weighty evidence as to the character and influence of our formulated therapeutics should be found in the methods by which young men just from the colleges make selection of drugs and define their application. Older men may readily drift from conscious application of the scientific principle in therapeutics, and their methods become crystallized into seeming empiricism, even from an original scientific solution. But young men, fresh from the teachings of recognized authorities, should then, if ever, exemplify scientific methods.

Yet one can not be brought much in contact with hospital internes without being impressed with the indefiniteness of their ideas regarding the indications for the use of specific drugs, and their uncertainty as to their effect and value. Drugs with them seem to be gathered into classes, not individualized, save as one is made to stand for the class, and their value to be measured solely by the outcome of a given case, rarely by their action upon systemic functions.

With astonishing frequency, too, one finds them connecting these drug classes with special diseases, and with these only. It is rather seldom that they voluntarily attempt any analysis of disease as a complex of temporarily excited but, under the conditions, normal activities, with the object of using drugs to modify and harmonize these conservative forces. Some years since I found my house physician, an unusually good man too, with a list of all the cathartics, which he was testing to see "how soon they came through." And another member of the staff asked which I considered the best heart tonic, strychnine or digitalis. Such experiences, however, cease to be surprising when we examine current works on practice for definite directions, based on physiological action, for the use of drugs.

What we find, or rather fail to find, doubtless should not be regarded as indicating any lack of knowledge. On the contrary, the surprising absence of precision of statement indicating the dependence of the values and applicability of drugs upon their influence on special functions seems rather to be the result of overfamiliarity with the subject, and a consequent unwarranted, even if complimentary, assumption of knowledge on the part of the student.

I will limit myself to two typical illustrations in support of the foregoing statements, strychnine and oxygen as used in pneumonia. If one goes back even ten years he will find hardly any mention of strychnine in the treatment of pneumonia in the works then current. Yet its physiological action was as well known then as now, and an analytical study of the pathic processes in pneumonia should have disclosed its value and defined the indications for its use.

Passing to works issued during the strychnine boom, while it finds a place in all, one looks in vain for ex-

plicit directions for its use. It is simply described as a cardiac tonic or stimulant. The same statement fairly defines its consideration in even the most recent systems of medicine. Of these, one which justly holds a position among the leading American authorities dis-misses it with the statement that "the indications for its administration are the same as those requiring alcohol." While others lay more stress upon its value, some even affirming its superiority to all other heart tonics, their statements as to the nature of its action and the indications for its use are no more definite, but seem rather to ascribe its superior value to difference in degree, not character, of action.

In one English system, corresponding to the American work quoted, we do find definite reference to its influence upon nerve centres; but our awakened hope of logical deductions sharply defining its applicability and differentiating it from other heart tonics is rewarded only by the hesitating and obscuring statement that "it is most valuable in heart failure when alcohol seems useless or even mischievous to the patient." "Who shall decide when authorities thus disagree?" Can it be true that our therapeutics is so devoid of science that we must experiment with each patient before knowing whether to use strychnine, alcohol, or digitalis? Or is it true that the physiological action and hence therapeutic value of all these drugs are the same? Are there no conditions of functional derangement which render the one more effective than another? If so, then let us honestly though mournfully confess that even *similia similibus curantur* is to be preferred.

Yet certainly it is true that cases of pneumonia evince wide variations in their manifestations of systemic depression. That case which is ushered in with severe circulatory disturbances, capillary and venous turgescence, irregular, uneven pulse, and passes quickly to a condition of stupor, with irregularly fluctuating temperature, surely can not be considered the equivalent, clinically, of another where the mind is clear until the last, and the pulse begins to waver in rhythm and force only with the advent of secondary invasions or oedema. We can not help believing that the former, with its profound depression of reflex centres, as obviously and definitely demands strychnine for the stimulation of these centres, and contraindicates alcohol, as the other requires alcohol without strychnine for the support of the excessive muscular and fibrile activities. In the one the heart fails from the first through loss of central contractility; in the other, only after a long struggle from simple exhaustion of muscular power.

It may be objected that this differentiation is foolish. I can not admit it; nor do I hesitate to say that the recognition of strychnine as a stimulant of reflex centres, and of alcohol as supplying force for the fibrile processes, affords at least a logical, if not the only rational, scientific basis for their use as heart tonics in the treatment of acute diseases. Certainly, until leading

authorities cease to be absolutely contradictory in their therapeutic dicta, we may wisely refrain from citing clinical results in proof of the scientific character of our methods.

When we pass to the consideration of oxygen there is revealed a similar and even greater indefiniteness of statement as to the indications for its use and the limitations of its applicability.

I have taken pains to question many young men on this point, and have yet to find one who had ever thought of oxygen as having any other effect than that of supplying a deficiency in the blood, or whose administration of the gas was controlled by a consideration of all the functions of respiration as applied to the pathic conditions existent in pneumonia.

For a long time there has prevailed a well-recognized and often plainly spoken doubt among medical men as to the value of oxygen which is the legitimate result of clinical experience. No more significant or pertinent comment can be made than the following quotation from Allbutt's *System*: "When dyspnea is urgent and the patient apparently dying of cyanosis (?), the inhalation of oxygen is a rational mode of treatment and has been advocated for many years past, and it sometimes proves remarkably useful. It seems never to do any harm (?), and it is a matter of surprise that its effects are not more uniformly and obviously beneficial. *It is possible that we have yet to learn how to use it most efficiently.* At present it takes its place among the adjuncts of successful treatment." If this is all we find in such an unquestionably scientific work, what hope can one have to look further? I shall be indebted for the reference to a standard work on medicine where attention is called to the facts that respiration is concerned quite as much in the elimination of carbon dioxide as in the absorption of oxygen, and that the increased rapidity of respiration in the early stages of pneumonia is not due solely to decreased lung capacity, but in part to an augmented systemic demand for oxygen to supply the fibrile processes; or to one which, without reference to these physical facts, makes it plain that, since the exciting cause of respiration is deficiency of oxygen in the blood, too free administration of the gas, through the removal of this stimulus and a consequent diminution of respiration, results in coincident lessening of the elimination of carbon dioxide and corresponding increase of carbonic poisoning; an increase of the very condition which, in a large proportion of cases where oxygen is used, is the primary cause of heart failure and death; the contradiction, too, for the specific antagonism of which we use strychnine.

Unfortunately as a physician, the value of oxygen may be, we are not to doubt, a great one; even this to the extent of producing such a potent narcosis. Nor may we permit our satisfaction at a somewhat diminished respiration followed by disappearance of cyanosis to blind us to the rapidly developing pallor and mental

torpor which presage central paralysis from carbonic poisoning. That these criticisms on the use of oxygen are justified we must maintain, for we have seen it given to the point of producing Cheyne-Stokes respiration and coma—conditions which disappeared when it was withheld.

Yet it should be possible to obtain its valuable action without the production of more than counterbalancing injurious effects.

Upon the basis of its relation to respiration, it seems evident that it should not be reserved until the later stages of the disease, for moments when the patient is *in extremis*; when rapidity of respiration is due to cardiac failure and diminished respiratory area, which is quite as inadequate for the excretory function as for oxygen absorption. At such times its use represents a choice between two evils, and its value is limited to the least possible reduction of respiration which will suffice to avert muscular respiratory exhaustion. Even in these moments of crisis we may often distinguish between conditions due primarily in one case to lack of oxygen or in another to carbonic excess, and thereby modify our use of oxygen.

Its greatest value, therefore, is evidently in the early stages, when the suddenly developed and intensified functional activities of the febrile processes entail an augmented oxygen consumption which is supplied from the decreased respiratory areas only at the cost of cardiac and respiratory strain. If given persistently and in minimum doses, therefore, from the onset of the disease, oxygen should and, I am convinced from a moderate experience, does produce very definite and satisfactory results, not only immediate, in modification of the pathic processes, but contingently, in minimizing those later conditions of crisis which alone are commonly accepted as indicating its use. I believe that when used thus, in harmony with the entire physics of respiration and pneumonia, oxygen will attain its legitimate position in the therapeutics, not only of this, but of allied diseases as well.

Further illustrations are unnecessary to make clear the point at issue, which is simply that in the confusion attending the deluging storm of new drugs which has marked the past decade, the inevitable rush to adopt the best has been productive of superficial analysis of cause and effect, even if it has not at times entirely obliterated logical processes controlling forces in our therapeutic work, not only with the new but also with old, established drugs. My plea, then, is not for more knowledge, but simply for a more *scient* title and exhaustive analysis of the facts in hand, to the end that our clinical therapeutics may keep pace, *non de nomine, sed de facto*, with abstract scientific investigation, and thereby unqualifiedly merit that laurel crown which should ever be reserved for and bestowed only upon manifest power to control disease and relieve suffering.

REPORT OF A NECROPSY IN A CASE OF ACROMEGALY, WITH A CRITICAL REVIEW OF THE RECORDED PATHOLOGIC ANATOMY.

By LOUIS J. MITCHELL, M.D.,

AND

E. R. LE COUNT, M.D.,

ASSISTANT PROFESSOR OF PATHOLOGY, RUSH MEDICAL COLLEGE, CHICAGO.

(Continued from page 521.)

PART II.

By Dr. LE COUNT.

THE variety of titles under which the few pre-Marie cases of acromegaly were reported form a curious illustration of the trend and evolution of medical thought.

Sauccrotte and Noël in 1772 and 1779 reported a case as "considerable enlargement of the bones in an adult person." Alibert, in 1822, described an instance of acromegaly in a scrofulous giant. In his work on the physiology of the nervous system, Magendie, in 1839, referred to two cases as examples of "hypertrophy." The case described by Chalk in 1855 received its title from a complication, "partial dislocation of the lower jaw from enlargement of the tongue." Friedrich in 1868 entitled two cases "hyperostosis." Verga (1869) and Tarulli (1879) reported cases which, from the facial enlargement, were called *prosopectasia*, and Lombroso in 1869 described a case under the title of *macrosonia*. To the credit of Brigidì belongs a case reported in 1877 as "anatomico-pathological studies of a man who became strangely deformed."

Langer, in 1872, gave to the scientific world some excellent descriptions of the skulls of acromegaly. Henrot, in 1877 and 1879, from the changes in the skin, reported a case of acromegaly as *myxedema*, and Fritsche and Klebs (1884) a case as giant growth ("*Riesenwuchs*"). Hadden and Ballance, in 1885, showed a case to the Clinical Society of London as an example of "hypertrophy of the subcutaneous tissues of the face, hands, and feet." Concerning some of these cases the descriptions are too brief to accept them without reservation as undoubted cases of acromegaly, and in almost all the details also are too deficient to include them in any general review.

It remained for Pierre Marie, in the year 1886, under the comprehensive title, *Two Cases of Acromegaly, an Unusual Non-congenital Hypertrophy of the Upper and Lower Extremities*, to definitely name the condition recognized by a few previous observers and to establish its value as a clinical entity. As acromegaly the disease is now recognized, and many observations have not only corroborated the distinctness with which it exists, but have also broadened our knowledge concerning it.

Its relation to gigantism has been studied by Langer, Massalongo, Dana, Brissaud and Meige, and others; to exophthalmic goitre, by Lancereaux, Magnus-Levy, and

Murray. Its frequent combination with diabetes has been commented upon by Hansemann, Pineles, and Dallemange. The differences between acromegaly and leontiasis ossium or crania progenea have been elaborately dwelt upon by L. Meyer, Virchow, and Zuckerkandl. Cretinism and myxœdema, in which the hypophysis is sometimes diseased and the sella turcica enlarged, have been more clearly isolated from acromegaly by the work of many writers (*e. g.*, Boyce and Beadles, de Coulon, Schönmemann, and others).

The clear conceptions of acromegaly thus obtained have been instrumental in bringing to light much new knowledge by the promotion of accurate and more scientific observations and some valuable researches, experimental and otherwise.

Reference may be made in this connection to the work of Boyce and Beadles, of Rogowitsch, Schönmemann, Comte, and Howell.

Notwithstanding the numerous clinical and anatomical observations which have been made, and the efforts to place the origin of acromegaly upon some positive basis, attempts to formulate any idea of its pathogenesis from a detailed consideration of its pathological anatomy meet with much discouragement. The recorded autopsies are too few; they exhibit so many evidences of non-uniformity and incompleteness in detail and description, and in many we have only a few generalized descriptions from which to derive data. For these reasons only such features of the pathological anatomy of this disease will be considered as have occurred in sufficient numbers to warrant their being accepted as more or less constant characteristics. At the same time an effort will be made not only to draw attention to some heretofore neglected features of the morbid anatomy, but also to point out the relationship existing between the disease processes of acromegaly and a few other conditions.

The enlargement of the bony skeleton at certain points has become so well known, and has been so frequently described from the purely anatomical standpoint, that a recapitulation of these alterations would be useless. There is a much greater need for accurate descriptions of the histological changes in the bones. The instances where such changes have been described are too few in number and often limited to a single bone or to a few bones.

The enlargement of the viscera has been spoken of as "aplanchno-megalic." Not enough attention has been directed to this aspect of acromegaly. The marked enlargement of certain organs should certainly merit a more careful inquiry into its cause, and it is safe to say that in degree and constancy this increase in size is to be met with in no other condition.

The Liver.—As regards the liver, in twelve necropsies it is not mentioned at all; in nineteen, it is enlarged; in eight, normal. Of the three remaining cases, one is referred to as "small," one contained carcinoma

nodules, and one is dismissed with the term "fatty." The enlargement has seldom been placed in exact terms, as will be seen from the following: Bournville and Regnault, 4,300 grammes; Brooks, 3,770 grammes; Osborn, 3,230 grammes; Fritsche and Klebs, 2,800 grammes; Dana, 3,710 grammes; Thomson, 3,510 grammes; Dallemange (I), 5,910 grammes; Dallemange (II), 1,630 grammes; Schultz-Jores, 4,700 grammes; Mitchell and Le Count, 3,530 grammes; Linsmayer, enlarged, thicker than normal; Hansemann, large; Bonardi, enormous; Holsti, 39×23 centimetres; Hutchinson, slightly hypertrophied; Fratnich, very much enlarged; Pineles, somewhat swollen; Dalton, enlarged; Smith, general enlargement.

The microscopic examinations are also very meagre; connective-tissue increase and fatty degeneration are the changes which predominate in the few examinations made.

The Spleen.—The enlargement of the liver is no less striking than is the enlargement of the spleen.

Among twenty-five necropsies in which the spleen is mentioned, it is found enlarged in nineteen. This enlargement is very much marked: Thomson, 400 grammes; Dallemange (I), 920 grammes; Osborn, 1,000 grammes; Fritsche and Klebs, 750 grammes; Hutchinson, 900 grammes; Schultz and Jores, 880 grammes; Mossé and Daunie, 870 grammes; Brooks, 370 grammes; Mitchell and Le Count, 450 grammes; Holsti, 21×15 centimetres; Claus and Van der Stricht, $20 \times 10 \times 7$ centimetres; Roxburg and Collis, 19×10 centimetres; Strümpell and Zenker, $18 \times 10 \times 5$ centimetres; Fratnich, larger than normal; Henrot, hypertrophied; Bonardi, twice the normal size; Linsmayer, three times the normal size; Dalton, enlarged; Smith, general enlargement.

Of the remaining cases, in one it is mentioned as small; in one case the weight was 160 grammes; in another, 145 grammes; in still another, 200 grammes. In the case reported by Boltz and Fraenkel, the size is given as $13 \times 7 \times 3.5$ centimetres. In three cases it was stated to be normal or unchanged.

The Kidneys.—The kidneys are also found enlarged, as a rule.

In thirty necropsies, in which their condition is referred to in any way, they are found enlarged twenty-one times. This enlargement is considerable in the majority of cases, as shown by the following list: Brooks, weight together, 680 grammes; Johnstone and Monroe, weight together, 365 grammes; Hunter, weight together, 530 grammes; Bonardi, right, 210 grammes—left, 222 grammes; Schultz and Jores, right, 400 grammes; left measured $16 \times 9 \times 5$ centimetres; Osborn, right, 310 grammes—left, 225 grammes; Fritsche and Klebs, right, very large—left, 275 grammes (smaller); Dana, right, 365 grammes—left, 400 grammes; Thomson, right, 310 grammes—left, 380 grammes; Dallemange (I), right, 550 grammes—left, 620 grammes; Mitchell and Le

Count, right, 360 grammes—left, 300 grammes; Strümpell-Zenker, left measured $17 \times 11 \times 4$ centimetres; Holsti, left measured 14×7 centimetres—right, same size; Linsmayer, somewhat enlarged; Hansemann, large; Roxburg and Collis, both enlarged; Bailey, both large; Pineles, swollen; Henrot, left kidney hypertrophied; Frasnich, larger than normal; Dalton, enlarged.

The Heart.—We find the heart mentioned more frequently. It is found enlarged to the following extent: Bourneville and Regnault, 750 grammes; Brooks, 425 grammes; Bonardi, 650 grammes; Dallemenge (I), 885 grammes; Dallemenge (II), 830 grammes; Worcester, 540 grammes; Gauthier, 400 grammes; Fritsche and Klebs, 550 grammes; Osborn, 1,160 grammes; Dana, 650 grammes; Mitchell and Le Count, 450 grammes; Linsmayer, diameter, 19 centimetres—length, 15 centimetres; Strümpell and Zenker, diameter, 10 centimetres—length, 15 centimetres; Holsti, diameter, 17 centimetres—length, 16 centimetres; Schultz and Jores, much enlarged; left ventricular wall, 2.5 centimetres; Wolf, enlarged; Rathmell, hypertrophied; Thomson, large; Brigidi, heart dilated, aortic insufficiency; Frasnich, enlarged; Hutchinson, slightly enlarged; Sigurini and Caporiaco, hypertrophied; Claus and Van der Stricht, slightly hypertrophied; Bailey, moderate hypertrophy; Dalton, enlarged.

This enlargement of the heart is very remarkable. If it is true, as Howard claims in his article on Heart Hypertrophy, that the size of the heart in compensatory hypertrophy may be considered as an index to the amount of obstruction which is being compensated for, then in the majority of cases of acromegaly there is an increased resistance in the circulation.

A study of the tables given by Howard also shows that arteriosclerosis is the most frequent cause of heart hypertrophy, and that the increase in the weight of the heart in such cases is very startling.

However, enlargement of the heart is not a constant characteristic of acromegaly, for in eight cases it does not occur. Hansemann, brown atrophy; Mossé and Daunic, not increased in size; Roxburg and Collis, normal; Dallemenge (III), atrophied; Henrot, a curious atrophy of the heart and blood-vessels; Boltz-Fraenkel, width, 11.5 centimetres—length, 11 centimetres; Pineles, contracted; Johnstone and Monroe, 255 grammes.

The Thyroid Gland.—A great deal of attention has been paid to the condition of the thyroid gland in this disease. Furnival states that the thyroid has been examined in twenty-four cases, and found normal in only five; further, that it is hypertrophied in more than one half of the twenty-four. The following list will indicate more clearly that enlargement has been quite generally observed: Osborn, 101 grammes—an accessory thyroid weighed 36.5 grammes; Dana, 120 grammes; Squance, 60 grammes, enlarged; Bailey, 84 grammes; Mitchell and Le Count, 70 grammes; Smith, 180 grammes; Holsti, much enlarged; Henrot, four or five

times too large; Fritsche and Klebs, increased in size; Gauthier, enlarged; Wolf, enlarged; Hansemann, some enlargement; Mossé and Daunic, increased in size; Brooks, symmetrically enlarged; Strümpell and Zenker, enlarged; Schultz and Jores, much enlarged; Boltz and Fraenkel, considerable enlargement; Furnival, slightly enlarged.

The thyroid gland has been found, according to the necropsy reports, as reduced in size, four times; as cystic or the seat of colloid degeneration, twice; and as normal in appearance, five times. In the remaining cases no mention of its condition is at hand.

The Thymus Gland.—As regards the thymus gland, to which attention has been especially directed by the researches of Klebs, it has been found persistent eight times, as follows: Squance, 56 grammes; Mossé and Daunic, 13 centimetres long; 4 centimetres wide; Roxburg and Collis, 9 centimetres long, 4 centimetres wide; Brooks, 6 centimetres long, 2.5 centimetres wide; Schultz and Jores, 13 centimetres long, 8.5 centimetres wide; Fritsche and Klebs, projected up to the thyroid; Holsti, imbedded in a mass of fat; Dalton, persistent.

The thymus has been noted as absent eighteen times. No mention of it is made in the remaining cases.

Concerning the other visceral changes, too few data are at hand to draw any conclusions from, but it is interesting to note that in the eleven cases in which the stomach is mentioned, six refer to an enlargement of the organ; also that the adrenals are spoken of six times, twice being dismissed with the mere statement, "normal." Once they are described as "thin," once as having undergone fatty degeneration, and twice they are stated to be enlarged. In the present case the adrenals weighed together thirty-six grammes.

The Hypophysis.—The few good descriptions of the histologic changes in the hypophysis are remarkable in view of the prevalent opinion that changes in this body are responsible for the disease. In many cases no microscopic examination is recorded; in many others we are forced to accept the conclusions of such examinations. These deficiencies are in marked contrast to the almost universal statements concerning an enlargement. The following list shows that not only is enlargement the rule, but that great variation exists: Dana, weight, 4.5 grammes; Worcester, weight, 58 grammes; Gauthier, weight, 13 grammes; Sigurini and Caporiaco, weight, 300 grammes; Rathmell, weight, 30.76 grammes; Bonardi, weight, 2 grammes; Comini, weight, 10 grammes; Mossé and Daunic, weight, 36 grammes; Bailey, weight, 8 grammes; Tamburini, length, 53 millimetres; breadth, 29 millimetres; thickness, 20 millimetres; Hansemann, breadth, 30 millimetres; height, 20 millimetres; thickness, 25 millimetres; Brooks, antero-posterior diameter, 15 millimetres; height, seven millimetres; Schultz and Jores, antero-posterior diameter, 40 millimetres; height, 20 millimetres; breadth, 40 millimetres; Holsti, antero-posterior diameter, 25 millimetres;

transverse diameter, 30 millimetres; Henrot, antero-posterior diameter, 30 millimetres; transverse diameter, 42 millimetres; Thomson, four or five times normal size; Brigidì, marked enlargement; Dallemange (I), size of a pigeon's egg; Dallemange (II), size of a cherry; Dallemange (III), a little tumefied; Squance, considerable hypertrophy; Roxburg and Collis, size of a walnut; Wolf, size of a goose egg; Caton and Paul, size of a Tangerine orange; Uthoff, extended into the third ventricle; Bourneville and Regnault, compressed the optic chiasma; Strümpell and Zenker, size of a walnut; Claus and Van der Stricht, $32 \times 12 \times 21$ millimetres; Boltz and Fraenkel, a cherry-sized tumor; Pineles, size of a cherry; Johnstone and Monroe, hypophysis large; Hutchinson, enlarged; Hunter, twice as large as normal; Rolleston, size of a walnut; Lawrence, size of a cherry; Smith, 7.5×6.4 centimetres.

In five necropsies no mention is made as to the size of the hypophysis, or of the tumorlike growth which occupied the position of this body.

The enlargement has been attributed to a variety of conditions. Most of these have to do with true tumors; some, however, are attributed to simple hypertrophy; in other cases competent observers have with praiseworthy honesty confessed their inability to decide between tumor formation and hypertrophy.

The thought suggests itself at this point, that if accurate histologic descriptions of these growths had been recorded, we would not find acromegaly ascribed to such a variety of pathologic changes in the hypophysis, and that some general laws could be formulated which would govern the variety of gross anatomic conditions observed.

In 1897 Tamburini, in a *résumé* of the findings in the hypophysis, declares that in thirty necropsies there was always an enlargement of the hypophysis, and that this enlargement is usually due to a simple hypertrophy, or to a complete adenoma, in which the principal elements of the organ are preserved. Hence he concludes that acromegaly does not depend upon abolition of any function of the hypophysis, since it is never observed in instances of atypical tumors, but that it does depend upon an excessive function of that organ.

Hansemann has also recapitulated the conditions met with in the hypophysis, and in forty-eight necropsies finds tumors recorded thirty-two times. Sternberg gives the changes recorded in the hypophysis as follows: Simple hypertrophy, twice; adenoma, seven times; hypertrophy and colloid degeneration, once; marked colloid degeneration and hemorrhage, once; cystic tumor, twice; sarcoma (variety not specified), five times; sarcoma or glioma, once; spindle-cell sarcoma, once; cylindroma, once; round-cell sarcoma, once; large-cell sarcoma, six times; glioma, once; adenoma (without enlargement), once.

From the summary of Schütte the following are gleaned: Simple hypertrophy, twice; adenoma, eight

times; lymphosarcoma, five times; glioma, once; glioma and round-cell sarcoma, once; colloid degeneration and hypertrophy, twice; sarcoma (variety not specified), nine times; cystic, four times.

From a comparison of these summaries it will be at once apparent that sarcoma and adenoma are the most frequent conditions reported. It is also apparent that acromegaly does not accompany any single pathologic change in the hypophysis. If any further evidence were needed to corroborate the last assertion, some of the more complete histologic descriptions of the cases in which sarcoma has been described will serve the purpose.

Strümpell and Zenker report a tumor made up of large round or polygonal flattened cells, with large, centrally located nuclei. Some possessed two or three nuclei, and at many points the cells were in contact. Around the large blood-vessels the tumor cells were numerous and somewhat columnar. At the upper part of the growth the appearance was more like the normal hypophysis; below it was more like sarcoma. The tumor had invaded the bone. In Wolf's case hyaline degeneration of the blood-vessels was observed. Sternberg places this growth among the cylindromas. The tumor cells were the size of red blood-corpuscles and round; the bone was eroded.

Dallemange (Case I) describes a sarcoma surrounded by a firm fibrous capsule.

Mossé and Daunic observed in their sarcoma a framework of fine bands of connective tissue and many newly formed blood-vessels. The tumor cells were fusiform, with undulating ends, and round or oval nuclei were occasionally grouped in bunches. The fibrillation of the cells was very marked. Claus and Van der Stricht observed a substitution of lymphoid tissue for the hypophysis. They state that it mostly resembles a lymphosarcoma, but also describe a network rich in capillaries immediately in contact with *glandular tubes* (italics ours). The large tumor described by Sigurini and Caporiaco as a lymphosarcoma possessed a distinct capsule, and fibrous trabeculae extending into it. There is no mention of invasion or erosion of bone.

Schultz and Jores, in a case where they were unable to decide between hypertrophy and adenoma, state that the central part of the growth had the appearance of an angiosarcoma.

Another large growth observed by Caton and Paul, and diagnosed as round-cell sarcoma, possessed a distinct capsule, which had become perforated at one point. The growth was soft and dotted with hemorrhages. The growth described by Roxburg and Collis was found to possess characteristics midway between sarcoma and glioma. Hansemann has described "a sarcomatous struma." It consisted of large oval cells, fine intercellular substance, marked fatty degeneration, and considerable development of blood vessels.

Through the courtesy of Dr. J. R. Ruttmel, of Chattanooga, Tennessee, I am able to include a description

of the growth in the case reported by him,* which had been preserved in alcohol.

(To be concluded.)

THE TREATMENT OF SYPHILIS.†

By BOLESŁAW LAPOWSKI, M.D.

THE development of bacteriology has had a marked influence on the treatment of infectious diseases, not only causing us to abandon, in both acute and chronic cases, those remedies which were sanctioned by the weighty authority of clinical observation, but also inducing us to leave the course of these affections to "mother Nature" until a remedy, acting on Nature's own principles, should be offered us.

Syphilis alone among all chronic infectious diseases has withstood the attack of the new trend in medical science; not only do we not trust to "natural help," but we interpose with mercury, a remedy which is inimical to all organized life. Attempts have been made to supplant this remedy by a serum (1) supposed to contain elements kindred to those which Nature uses for her defense, but after a very brief trial it was consigned to an oblivion from which, let us hope, it may emerge with brighter prospects of success.

Until this hope is realized mercury must reign supreme in the treatment of syphilis, since it has for centuries proved itself to be an indispensable factor and an invaluable means of securing to the patient life and health. It is justly appreciated as the best, perhaps the only, known means for maintaining this health and life, an opinion embodied in every standard medical treatise on syphilis by common consent of all syphilographers.

But right here the syphilographers cease to agree. When the questions are brought to the forum of medical men—when to begin the administration of mercury? how long to continue the treatment? what is the best preparation of the drug? and by what method to introduce it into the system?—the answers are so confusing, the arguments so contrary, that thinking physicians naturally look to the physician's physician, the laboratory savant—ordinarily shunned, but heartily welcomed in the day of trial—"to be," as Lord Bacon says, "the light to open their eyes to see their ways through the labyrinth, and find the clues that shall conduct them to the truth."

Our savant may, then, discover the syphilitic virus, and, should he do so, does this presuppose, or even promise, that the remedy shall be simultaneously discovered? And when this last result is obtained will the tocsin

"Ring out the old

And ring in the new" treatment?

* *Journal of the American Medical Association*, 1897, vol. xxviii, p. 549.

† Read before the Genito-urinary Section of the New York Academy of Medicine, March 11, 1899.

Meanwhile, what are we to do? Let us see if no basis is to be found upon which we can build our plan of treatment. Can we not obtain certain principles from the classified results of countless observations of the course of syphilis during its centuries of existence and construct upon them a basis for the treatment of syphilis?

Having had during the last twelve years of my practice the opportunity to study the effects of various preparations of mercury administered in different ways—in form of inunctions and hypodermic injections during my five years' service in the department of skin and venereal diseases of the general hospital in Warsaw, as first assistant to Dr. Antoni Elsberg; and in form of internal administration by mouth and sometimes by inunctions, during my seven years' experience in this city, in the outdoor departments of the New York, Presbyterian, and Skin and Cancer hospitals—I have come to appreciate the method of inunctions as the one which is necessary to apply in severe cases of syphilis, and advisable to use in the usual forms of the disease, owing not only to the better results obtained by this method, but to the absence of the drawbacks which are inherent in the other methods.

I will now endeavor to bring before you the principles upon which this conclusion is based.

The safest guides in the administration of mercury to a syphilitic patient are the action of mercurial preparations upon the syphilitic virus and their effects upon the human organism.

The first requirement may be fulfilled by mercury in two ways: First, by killing the specific agent and neutralizing its toxine, from a direct and antiparasitic action; second, by increasing the defensive power of the human organism by stimulating the functions of the organic elements to produce an antitoxine, and thus, in an indirect manner, to enable the system to overcome the depressive tendencies of the syphilitic poison (2).

That mercury does not act as a direct antiparasitic remedy in syphilis is made more than probable from a consideration of the following points:

First. In countries where for centuries syphilis has been treated by mercury the number of victims of syphilis is not diminished.

Second. In countries where syphilis is rarely or never treated by mercury the number of syphilitics is not increased. The hygienic conditions of the inhabitants of both countries are presumed to be the same.

Third. The presence of mercury in the system neither protects an individual from being infected with syphilis (as shown in cases unsuccessfully treated with mercury for mistaken syphilis, the patient during the treatment acquiring syphilis (3), and in workers in factories where mercury is used, who acquire syphilis even during their stay in the factories), nor does the administration of mercury prevent a relapse of the syphilitic symptoms during the time of its administration.

Fourth. Mercury has a beneficial action in other diseases, as epithelioma, lupus (4), psoriasis (5), and lepra (6).

Fifth. Other remedies, especially irritants, also modify the syphilitic eruption, sometimes even producing salivation, which does not clinically differ from mercurial salivation (7).

Sixth. Both syphilis, in certain periods of its development, and mercury attack the same cell centres, producing manifestations upon the skin and mucous membranes which are clinically so much alike that the decision whether they are due to syphilis or to mercurial poison sometimes tasks the diagnostic powers of the most skillful clinician. As to the effects of mercury upon the human organism, they depend upon the amount of mercury introduced into the circulation; and consequently that method meets our approval which enables us to administer the largest amount of mercury in the safest manner.

We have different ingenious methods of introducing mercury into the organism, but we have none by means of which we can trace its passage through the human body, and this gives rise to the difference in opinion concerning the manner and chemical form in which mercury is absorbed. The opinion of some, that when mercury once enters the system it is absorbed as a double chloride of mercury and sodium (Miahle), is not accepted by others, who maintain that it is taken up as an albuminate of mercury (Voit).

Others (Rabuteau, Merget, Anuschat), again, hold that it circulates in the body juices as a mercurial vapor, in the form of very minute particles of metallic mercury; and this opinion is upheld by chemical investigations upon mercury outside of the human body, and by observations of its changes while remaining in the human or animal organism.

This is demonstrated especially regarding sublimate and calomel:

First, by Anuschat's observations, which show that the action of sublimate in the system is due to hydrogen and oxygen *in statu nascendi* (8).

Second, by microscopical and chemical demonstrations of Justus, who found in the blood of a syphilitic patient who was treated by intravenous injections of sublimate "grayish-black granules, which must be considered as the reduced mercury in its metallic form" (9).

Third, by Smirnof's demonstrations of globules of metallic mercury after hypodermic injections of calomel in syphilitic patients (10).

Fourth, by numerous experiments upon animals, which showed that nearly every combination of mercury, even calomel itself, when injected hypodermically, is decomposed, forming minute globules of metallic mercury around the area of the inflamed nodule (11).

Furthermore, this opinion is sustained by clinical evidences of the action of different mercurial prepara-

tions upon syphilitic manifestations. All syphilographers agree that preparations of metallic mercury exercise the best action upon the syphilitic virus, and that by their aid we can obtain good results in severe cases where other mercurial preparations have failed to exercise any influence upon the syphilitic virus (12).

Moreover, that mercurial compound acts quicker and better which contains the largest amount of metallic mercury and from which the system extracts the largest quantity of the metallic element present in that particular preparation, dependent also upon the individual tendency to absorption and upon the length of time the remedy stays in the system. Thus, a given dose of calomel, containing eighty-five per cent. of metallic mercury, acts more surely than a dose of sublimate, which contains seventy-three per cent. of metallic mercury, owing to the fact that sublimate remains a shorter time in the human body and is eliminated sooner than calomel, thus leaving the system before its metallic mercury is extracted.

We see, then, that the mercury which is brought into circulation will exercise its influence upon the syphilitic poison according to the amount of metallic mercury the system can and does extract from the preparation.

All therapeutic preparations of mercury contain metallic mercury either in plain globular form or in some other chemical combinations.

Let us consider whether it is of more advantage to introduce the plain metallic mercury or its chemical combinations, out of which the patient's organic laboratory will extract the desired metal. The mercurial preparations can be introduced endermically, hypodermically, *per os*, by means of intravenous injections, or by inhalation. The best way, according to our standpoint, would be to introduce mercury by fumigations, as by this method it is at once brought into contact with the skin and mucous membranes in the most active form—viz., vaporized mercury. But the dangers which are connected with this method, as severe stomatitis, laryngeal spasm, and even in some instances death (13), make us forego its advantages and look for a safer and easier but not less efficacious procedure.

The next method which should attract our attention would be intravenous injection of mercurial preparations, since it introduces into the circulation an exact amount of mercury, which, being at once transported to all parts of the system, will have a prompt effect. But, as up to the present time nobody, to my knowledge, has injected either metallic or insoluble mercury into the human venous system, and as my own experience with soluble intravenous injections is limited, I must now refrain from considering this method.

The advantage of being able to administer a precise dose with no immediate inconvenience to the patient would attract our attention to the third method—namely, *per os*, by means of which mercury is administered either in solution or in pill form. Here the prepara-

tions of mercuric and mercurous oxides, the double combinations, and metallic mercury are used.

The disadvantage common to the first four preparations, as compared with metallic mercury, is, that the organism, before deriving any benefit from the preparation, has to decompose it into metallic mercury prior to its removal in the faeces.

As a larger amount of metallic mercury can be made use of with less strain upon the digestive organs by taking the blue pill or gray powder, we shall easily understand the choice of and faithful adherence to the blue pill and gray powder by generations of the most practical people on the globe. Of late, attempts are being made to introduce the metallic mercury in pill form in Germany, but the number of observations is not sufficient to allow any conclusions to be drawn (8, 14).

No matter what the mercurial preparation is, so long as it is administered by the mouth, it gives rise to serious, undesirable effects, impairing the normal functions of organs, the activity of which is necessary not only to enable the living system to increase its defensive powers by taking in and assimilating the required amount and proper kind of food, but to prevent the production of gastric toxins which may give rise to cerebral symptoms, often erroneously ascribed to the syphilitic poison (15, 16).

But the most deadly blow was given to this method by proving its inefficacy against the syphilitic poison. Mercury, when given *per os*, is absorbed by the venous system of the portal vein and deposited in the liver, to be discharged again into the intestinal channel; thus only a very small amount is carried by the general circulation to other organs—for instance, the skin. Consequently, in a great many forms, even of early manifestations of syphilis, another, a more effective method, the hypodermic or endermic, is to be resorted to.

This recognized fact is inducing not only those who from force of habit are still using this mode of administration, but also those who brought this method into prominence, to seek some other manner of administration of mercury.

No wonder, then, that in the discussions which have lately taken place in the French Academy of Medicine many members have declared themselves in favor of a departure from the ancient methods; and observations upon observations are being published which tend to show the greater efficacy of the hypodermic method (17).

In this country the prevalent practice is still mostly limited to the *per os* method, largely due to the strong stand taken by an eminent syphilographer on behalf of this method (18).

When a clinician of such eminence as this syphilographer indorses a method of treatment, not only on account of the good results obtained by it, but, what is more important, claims for the method a "scientific

justification" (19), it is our duty before rejecting it to look into the accuracy of its scientific basis.

This advocate of the method *per os* asserts that mercury can better exercise its specific power over the virus if "so administered as to be a tonic"—i. e., in small, continuous doses—and from time to time being rushed to the "specific dose" (20). The tonic effect of such small, continuous doses he claims to have proved by the fact that the number of red blood-corpuscles was increased during the administration of such doses (21). Whether such a conclusion is correct depends upon the answer to the question: Is the increased number of red blood-corpuscles noticed in a drop of blood after the administration of a small "tonic" dose of mercury due to a genuine increase of the number of red corpuscles, or to a change in the concentration density of the organized elements of the blood, produced by the withdrawing of a certain amount of water from the general circulation? (22).

That withdrawing a certain amount of water from the general circulation is followed by an apparent increase of red blood-corpuscles in a given drop of blood is demonstrated in some normal and pathological conditions of life associated with loss of water from the system.

Thus, after physical exercise, a hot bath, in diarrhoea and cholera, the number of red blood-corpuscles is apparently increased. Furthermore, it is well known from clinical observations that small "tonic" doses of mercury produce an increase of all excretions, and consequently the blood may be more concentrated, showing a quasi increase of red blood-corpuscles. All this goes to show how careful we must be in drawing conclusions from a supposed increased number of red blood-corpuscles, even if the augmentation of the number of red blood-corpuscles is concomitant with a gain of weight of the body (23), as the latter is most probably due to the surroundings and mode of life of the patient. Not the quantity but the quality of the blood—the amount of hæmoglobin it contains—is the standard by which we have to measure the tonic effect of mercury upon the system, as was done by Justus, and he found that inunctions produce a larger increase in hæmoglobin than any other method of administration of mercury (24).

Deprived of its scientific basis, the method *per os* loses the strongest and the most needed justification for its recommendation, and this brings us to the consideration of the next method—hypodermic injections. The chief claim for this method is that it accomplishes *multum in parvo*—with small doses we can obtain great results; here the soluble and insoluble salts of mercury and pure metallic mercury are in use.

The effect upon the syphilitic manifestations and syphilitic diathesis is in accordance with the amount of metallic mercury extracted by the organism from the preparation, which usually depends upon the time the

preparation remains in the system and the quickness of its absorption; but with the prolonged sojourn and retarded elimination—with the increased amount of metallic mercury in the system—the dangers are increased. The least dangers are connected with injection of sublimate, as it is quickly eliminated by the system before the amount of metallic mercury of the preparation can be extracted, although cases are reported where death followed its administration (25).

The dangers which are connected with the administration of the insoluble salts and metallic mercury can be divided into three categories. Those of the first class can be easily avoided, as they depend mostly, if not entirely, upon the actions of the physician, who, by strictly observing the requirements of asepsis, will avert the occurrence of purulent abscesses, and by selecting the appropriate place for the insertion of the needle he can avoid the infliction of pain on the patient.

The second class of dangers is due to our incapacity to regulate absorption and to control elimination of the mercury when once it is in the system. We can hasten the elimination by various procedures, but we are powerless to stop it when it has once begun, so long as there is mercury in the circulation. By injecting an insoluble salt or metallic mercury a quantity is amassed from which the absorptive power can draw when an opportunity presents itself, and, circulating to an extent that is injurious to the tissues, it will produce severe forms of intoxication by destroying tissue elements, and is not rarely followed by death (26).

Although the victim may be sometimes saved by cutting out the mercurial depot, this procedure is not always sufficient to save life, because enough mercury may have already circulated in the system to irreparably injure it (27).

The last category is the most important, as the physician is entirely helpless when lung embolism is produced by injecting some of the mercurial mixture into a vessel (28).

The motto, then, *multum in parvo*, can be translated, "The less the patient takes of it the better."

These disadvantages should be sufficient to condemn the method as an everyday procedure, and to limit its use to very urgent cases, where a quick and strong action is desired, owing to the importance of the organ involved in the syphilitic process, as the eye and brain.

Of all the methods, not one fulfills the medical maxim, "*cito, tuto et jucunde*." If one is rapid in effect, the other is slow and uncertain, while the third, even if prompt in action, is by no means *tuto et jucunde*. Only one method meets all the demands that is, inunction—and it can be applied in every form and at every age.

In a method alleged as practical, *jucunde* plays an important rôle. The greatest objections are the uncleanness and the exposing of the patient's malady.

On account of the latter objection some other method may be employed, but only as a last resort.

Uncleanliness is a relative term, and varies with the habits of the patient and with the care the physician exercises in explaining the value of inunctions. It is claimed that in this country people will not permit themselves to be treated by this method, as it is, in the language of Keyes, "a dirty method at its best, and it is hard to get clean people to follow it conscientiously for any prolonged period" (29). But the assurance of Taylor, who says that in his experience "it is much easier to obtain the consent of patients in the upper walks of life to submit to and follow up the inunction cure than it is to deal with patients in a lower sphere of life" (30), and the statement of Dr. T. W. White, that an explanation of its advantages will suffice to insure its acceptance by an intelligent patient (31), convince us that the physician will not find it difficult to induce a patient to allow inunctions to be given him, especially when he can render the method less harsh by alternating it with the following *modus operandi*:

A piece of muslin or linen is made into a bag—like an ordinary pillow case—fifty centimetres long and forty centimetres wide. Its inner surface is smeared over with four to five grammes of the ointment and the bag is fastened to the shoulders, or wherever convenient, by means of straps. The ointment is thus next the skin, and vaporization occurs from the body temperature; and, as mercury is absorbed mostly by the lungs and only partly by the skin, the system is mercurialized rapidly and thoroughly (32, 33).

While other methods act quicker than inunctions, the effect is not lasting, and in syphilis *cito* is to be accepted as synonymous with *festina lente*—slow but sure. The effectiveness of inunctions is now recognized by many of its former opponents and induces them to acknowledge that they could not obtain the same results by any other method (34). Now, this is a very strong recommendation, considering that it comes from one of the most eminent advocates of the method *per os*, although it is only meant by its opponents to be applied to exceptional cases and not to treatment of the earlier forms of syphilis. But when we consider that all syphilographers, no matter what method or preparations they employ, advise a thorough and efficient treatment, especially in the early stage of syphilis, is it not advisable to use this method, the acknowledged most efficient one, also in early manifestations of syphilis? Furthermore, the method is the safest of all methods, although the occurrence of some forms of intoxication can not be denied. I am persuaded, however, that the force and effect of each of them have been greatly exaggerated, and that they can all be remedied and possibly avoided, not by any material alteration in the method itself, but by exercise of proper watchfulness.

In producing intoxication it is the amount intro-

duced into the system, and not the preparation of mercury administered, which is of prime importance.

The inunction method is open to the objection that the amount of mercury artificially introduced can not be definitely measured or determined; but we are always able to cut off the supply at the slightest sign of danger, and we do it in the pleasantest way for the patient, by means of soap and water and transportation to a fresh, clean, airy room.

The occurrence or absence of symptoms of intoxication—diarrhoea, salivation, tremor, or exanthemata—depends in nearly every case (idiosyncrasies excepted) upon what the physician does before, during, and after a series of inunctions. And we are thus led to consider how to proceed.

Before putting the patient under the influence of mercury we must examine his excretory organs, in order to ascertain whether they are able to eliminate the absorbed mercury without injury to their normal functions. The condition of the mouth, teeth, the absence of albumin and of sugar in the urine, the presence or absence of stone must be considered, and, if all is found satisfactory, we may proceed to the choice of ointments. This is a point of no small importance. By seeing that the blue ointment is free from rancid, irritable ingredients, as rancid fat and turpentine oil, we shall nearly always avoid skin symptoms due to external irritations. The metallic mercury in the ointment must be reduced to extremely fine particles in order to facilitate its entrance into the circulation. Lanolin, resorcin, and vasogen mercurial ointments have no special advantages as to absorption and action as compared with the blue ointment of the *United States Pharmacopœia*, provided the last is so prepared as to answer the requirements I have named.

The effect produced by the ointment upon the symptoms, their partial or complete disappearance, may in some cases guide our action during the application of the ointment, but when the eruption has disappeared it is always safer, before putting the patient under the influence of more mercury, to take pains to see that the power of elimination of mercury possessed by the kidney is not lessened by the presence of albuminuria or cylindruria. Then we shall discover the first evidence of intoxication before serious harm results to the patient in the form of diarrhoea, salivation, or a toxic eruption. It is hardly necessary to describe before this audience how to make inunctions. I shall only call attention to the principle underlying the effectiveness of inunctions. As the benefit derived from inunctions is mostly due to inhalation of mercury by the lungs, and only partly to skin inhalation (32, 35, 36, 37), all our endeavors during the course of the rubbings should be directed to selecting such a time and place, and adopting such a manner of application as will insure to the patient the best possible chance to inhale the mercurial vapors. Consequently, evening, especially the time be-

fore retiring, and a room kept at an even temperature, will best answer this purpose. It makes no difference how we rub in the ointment, so long as we take in as large an extent of skin as possible, so as to insure a larger surface for vaporization (38).

It is advisable to measure out the quantity of ointment required for each inunction.

I can not refrain from quoting the very practical and simple suggestion of Keyes regarding the manner in which this dosage of mercury is best accomplished. Keyes instructs the druggist to put into a separate box or bottle the quantity prescribed as proper for a simple inunction as a gauge for the patient to go by. The patient is instructed to take from his large box or bottle a portion about as great as that specially measured out for him, keeping the test dose to measure the others by. Inunctions thus administered will seldom give rise to any serious inconveniences; at least they will always be manageable.

Neither sex nor age nor form presents any contraindications for their use. On the contrary, they are one of the best methods in treating syphilitic infants, as integrity of the functions of the digestive organs is of paramount importance in infantile life, and is especially desirable when a strong, effective treatment is required. Other methods may be used as adjuvants, and in those cases when inunctions are contraindicated, as in people with a hairy skin, or those suffering from diseases of the skin in which its surface is affected. Here the bag application can be advantageously made, in combination with metallic mercury *per os*, or with soluble injections.

(To be concluded.)

THE TREATMENT OF GALLSTONES.*

BY WALTER LESTER CARR, M. D.

THE treatment of gallstones should be the management of the patient during the intervals of biliary colic, as well as the alleviation of symptoms at the time of the passage of the biliary calculi.

It is generally recognized that almost all patients who suffer from the formation of biliary calculi have either a predisposition to gouty or rheumatic disorders or a catarrhal disturbance of the intestine, induced by overindulgence in sweets, rich diets, and by sedentary habits. We find the majority of the patients are women, more often stout than thin, and, while thin people, men as well as women, have biliary concretions, the greater number of patients who come under treatment have considerable superficial adipose tissue, showing either an excess of or an imperfect oxidation of the food. The catarrhal condition of the intestines extends to the gall ducts and bladder, and the bacteria, most commonly the

* Read before the Society of the Alumni of the City (Charity) Hospital, March 8, 1899.

Bacterium coli commune, cause a deposit of cholesterol crystals.

As our first experience in the treatment of a patient with biliary calculus is generally during an agonizing paroxysm of colic, it may be well to speak of the acute condition and the best method of alleviating the pain.

A paroxysm of biliary colic is most severe from one to three hours after eating, while the food is passing from the stomach into the duodenum and the bile is flowing from the gall bladder.

To stop the pain is the first indication, and a hypodermic injection of morphine, one fourth of a grain, with atropine, one one hundred and fiftieth of a grain, repeated as needed, will quiet the patient better than any other means. Inhalations of chloroform will, in paroxysms of intense pain, be of special service. If the morphine be used first, chloroform may be administered for primary anæsthesia until the former drug has time to act. Hot applications are to be made over the abdomen, and the water bottle is to be kept at the feet to stimulate the circulation in the extremities. Hot baths are not always easy to give, but they do good to some patients.

Belladonna is thought to lessen the spasm of the cystic duct, but its administration by the mouth or by means of external applications will not be so satisfactory as the combination of atropine with the morphine subcutaneously. The same may be said of the use of the opium for a paroxysm. If the stomach is irritable and there is vomiting, it is best to reserve the opium for some other time. Occasionally opium may be given in a suppository or in an enema, but in severe cases the pain is so intense that it does not admit of this method when relief can be afforded by the morphine. In addition to heat to the abdomen and extremities, considerable relief may be experienced by draughts of hot water to which bicarbonate of sodium is added. Even if rejected, the hot water will clear out the stomach without depressing the circulation; and if retained, it has a salutary influence. Emetics and cathartics are contraindicated and should not be given during a paroxysm. If the abdomen is distended and the bowels are sluggish, a flushing of the large intestine will be a satisfactory means of relieving distention.

After the intense pain is over, if the bowels are constipated, a dose of calomel may be administered and followed in a few hours by the sulphate or phosphate of sodium.

A patient who is known to have gallstones, either the large concretion that fill the gall bladder or the "sandy bile" that irritates the ducts, should have judicious medical treatment and advice to enable him to overcome the conditions associated with the formation of biliary concretions.

The diet is to be restricted to eliminate fats, sauces, gravies, fried articles, pastry, and all rich foods that are likely to cause colicky attacks. Meats, fish, green vegetables, fruits, and bread are to be allowed, if there is no

contraindication. The condition of the patient must be recognized, as a stout woman who does not exercise will need less fat food than a phthisical man. At first it is best to cut off all fats and sugars, but so soon as the bile action is under control, sweet oil and butter may be allowed. Water is necessary from the first, not only to increase the fluidity of the bile, but also because water stimulates the blood-vessels of the intestinal and portal circulation. Vichy water has a good effect when taken early in the morning, a glassful from half an hour to an hour before breakfast, and an hour before luncheon and dinner. When Vichy is taken at the spring, there is a definite action from it; but for everyday purposes, the bicarbonate of sodium dissolved in water before meals, supplemented by doses of phosphate of sodium for laxative effect, will make a serviceable substitute in the treatment of people who can not go to spas or afford expensive mineral waters. Carlsbad salts and water are regarded highly by many practitioners, and justly so, as they have enough action on the intestines, gall bladder, and ducts to expel stones that have been retained for a long period. With the administration of any alkaline or saline, the first treatment should last for a month or six weeks, but after that time it is fallacious to continue the use of alkalines and salines except in an intermittent way, or to meet particular indications.

It must not be understood from the foregoing statement that Carlsbad and other salts are not serviceable, for the contrary is true; but it is irrational to depend upon these salts to expel all stones. The treatment is often carried on at the expense of the general nutrition without causing the passage of calculi, though intestinal peristalsis will be increased.

The drugs that are used with the idea that they dissolve the biliary calculi are chloroform, ether, and turpentine. For a great many years ether and turpentine have had a place in the treatment of calculi, because of the supposition that they either dissolve or saponify the gallstones. They are administered in doses of two or three drachms. There is no doubt but that the oil of turpentine is a good stimulant to the intestine, and that it possesses bacteriological value, but it is questionable how much of the saponification of the bile is due to its combination with solid cholesterol masses. It is much more likely to stimulate the flow of the fluid bile than to break down old masses of cholesterol.

Ether has an action on bile, but it is doubtful if the gallstones are dissolved. Both ether and turpentine stimulate biliary flow, and in this way they assist small calculi through the cystic and common ducts to the intestine. Ether and chloroform relieve spasm, and the good effects observed when they are administered should be in part ascribed to the relief of pain. Ether is a recognized stimulant to the circulation and it acts quickly, so that the sense of well being is not always a positive guide that the gall bladder is discharging its con-

tents, though masses of bile may be seen in the stools. On careful examination, these will frequently be found to be saponified bile and not calculi of cholesterol crystals.

Sweet oil is lauded by physicians as a valuable agent in the treatment of gallstones. It does do good in some cases, but an inspection of the bile that is passed in the stools will show that many of the "calculi" are oil globules surrounded and intermingled with bile. Sweet oil is, however, a suitable agent for increasing peristalsis, and it will aid in the expulsion of stones even if it does not dissolve them.

Salicylate of sodium stimulates the flow of bile, and the drug is easy to administer and safely borne for a long period. Salol, salophene, and naphthalene are useful when intestinal antiseptics is required; but when the bile is dammed back by a complete occlusion, the administration of pills of bile coated with salol, two hours before meals, will prevent putrefactive changes in the intestine.

The cholate of sodium is also given for the same purpose.

The succinate of sodium in doses of five grains three times a day is a serviceable drug, and many patients are relieved by its use.

The succinate of iron peroxide is administered as a tonic and with an idea that the escape of oxygen will chemically alter the gallstones.

Massage of the abdomen with gentle manipulation in the region of the gall bladder will empty it of the small stones, but great care is needed that there shall be no impaction of large calculi.

Exercise to strengthen the abdominal muscles and increase the action of the diaphragm, fresh air, and regulation of diet will benefit all patients who are sufferers from calculi.

Surgical procedure is the only relief in an impaction, or in cases in which the gall bladder is distended with a number of calculi that are not acted upon by the treatment above indicated.

It is a medical matter to keep the patient with gallstones on a suitable diet with proper hygiene and medication; but the necessity for surgical interference should be considered when the symptoms are those of impaction, or when there are constantly recurring attacks of colic with the dangers of suppuration and perforation.

68 WEST FIFTY-FIRST STREET.

THE SURGICAL TREATMENT OF GALLSTONES (BILIARY CALCULI).*

By CARTER S. COLE, M. D.

IN accepting the responsibility for the surgical treatment of biliary calculus in the discussion arranged for this evening, I had not realized how much there was to be said about everything touching this whole subject, except the surgical side. I may be permitted to offer some suggestions quite opposed to surgical interference, and then give the conditions which justify operation, together with the variations of such procedures.

The clinical history and pathology have already been given at length, to say nothing of the medical means for relief, but from the surgeon's standpoint it may not be amiss to remind you that there are many contradictory facts connected with cases of biliary calculus. For example, in a case in which many calculi are present there may be no symptoms worthy of note for a long time, and when the condition is recognized simple medical methods may entirely relieve the patient; and in another case a single stone of small size may be the cause of an intestinal obstruction. Again, a small stone may completely block the common duct and give rise to aggravated symptoms of the trouble; a large stone may be passed by the bowel (after having ulcerated through in most cases) and be the first clue to the disease from which the patient has been suffering for a long time. In still another class of cases one or more stones may have already caused a single abscess or multiple abscesses of the liver before the condition has been suspected.

The site of the stone unquestionably influences materially the train of symptoms as well as the pathological sequelae. In the gall bladder one or more calculi may for a long time remain and do no harm. In the common duct or in the cystic duct a single small stone may conduce to a fatal termination of the case. We are usually first advised of the presence of a stone by its effort to enter the cystic or the common duct, although the colic may have occurred from the simple existence of the smaller stones before they entered either of the ducts or the gall bladder. The possibilities of distention of the ductus choledochus are unquestionably great, and yet it is more than likely that the large stones believed to have escaped through a distended duct have in reality done so by ulceration. So much, then, for the possibilities and some of the variations of the disease apart from surgical intervention. And granting that medical measures have failed (I need not remind you of cholate of sodium* as a preventive and curative agent; of olive oil, especially in

Food and Alcohol as Causes of Disease Respectively.
—The *Sanitary Home* for April quotes Sir Henry Thompson as saying: "I have come to the conclusion that more than half of the disease which embitters the middle and latter part of life is due to avoidable errors of diet; and that more mischief, in the form of actual disease, of impaired vigor, and of shortened life, accrues to civilized man from erroneous habits of eating than from the habitual use of alcoholic drink, considerable as I know that evil to be."

* Read before the Society of the Alumni of the City (Charity) Hospital, March 8, 1899.

† Danby. *American Journal of the Medical Sciences*, Philadelphia, 1876, vol. lxxi, pp. 410-413.

large doses, the knowledge of which has been recorded for many years and in many places, as well as in many lands; * of Sprudel salts,† and of the more uncertain and unsatisfactory succinate of iron,‡ and mercurial treatment,* going back to a previous century)—granting, I repeat, that these and other medical measures have failed to relieve frequent attacks of great severity, with or without jaundice, but attended by signs of a possible or probable suppurative inflammatory process, we are confronted by conditions demanding surgical intervention. The technical terms as collected in the text-book of Wharton and Curtis|| need only to be explained to cover the field of operative procedures:

1. Cholecystotomy, or simple incision, with subsequent treatment by drainage.

2. Cholecystostomy, in which the gall bladder is stitched in the wound after incision.

3. Cholecystodysis, in which the gall bladder is incised, the stones are removed, and the bladder is sutured and returned to the abdominal cavity without drainage ("ideal cholecystotomy").

4. Cholecystectomy, in which the gall bladder is excised.

5. Cholecystenterostomy, in which a connection is made between the gall bladder and intestine in order to provide for the entrance of bile into the gut.

6. Choledochotomy, or choledochendysis, incising or incising and suturing the common bile duct.

Practically, a simple incision is made over the tumor. If the gallstone is in the common duct and can be pushed into the gall bladder, or crushed *in situ* (as is often the case), and then pushed into the gall bladder; or, if it is already in the intestine and causes an obstruction; if it can be crushed by the fingers or rubber-guarded forceps without injuring the gut; or, if an incision must be made upon it, the parts are repaired, if possible, completely at the time. If suppuration is present, drainage by gauze, preferably, or by tube is used. The line of incision is of small import and varies with the individual case as well as with the tastes of the surgeon. An incision that does the least violence to the natural anatomical relations of the parts is preferable.

In suppurative cases the parts are usually already bound to the parietal peritoneum; if not, it is well to guard the abdominal cavity against contamination by stitching the tumor to the abdominal walls before opening. I have seen no special harm follow the introduction of clear bile into the peritoneal cavity. The

complete removal of the gall bladder is seldom desirable, but seems not to be followed by especially bad results. Let me remind you of the great value of pure carbolic acid applied by a swab to the cavity in which suppuration has occurred (here as elsewhere in surgery), as well as of the fact that we have its action under complete control by the use of alcohol, as discovered and detailed at a recent meeting of the New York County Medical Society by Dr. S. D. Powell. In cases where even a considerable amount of bile is discharged by the external opening, it has not been my experience to see much if any harm result; and sooner or later every patient has recovered without a biliary fistula. Again, it has seemed to me that the pure carbolic acid has contributed in no small manner to the result.

In conclusion, I may remind you that the care as well as the capacity of the surgeon are prime factors in the operation to be attempted; that in many cases a simple incision with drainage is entirely and eminently satisfactory; and that in all cases in which suppuration has already occurred, especial care must be taken to guard the abdominal cavity against infection. The means to this end must be decided at the time by the conditions with which we have to contend; although, personally, I feel great assurance in the power of pure carbolic acid to prevent the extension of the suppurative process as well as to relieve suppuration already present.

Therapeutical Notes.

The Treatment of the Bronchopneumonia of Measles.—A writer in the *Presse médicale* for February 25th (*Lyon médical*, March 19th) says that enveloping the chest with napkins soaked in cold water and partly wrung out is the most efficient remedy. As a stimulant, one may use Marfan's mixture, the formula of which is as follows:

R Sodium benzoate	7½ grains;
Ammonium acetate	21½ "
Old cognac	120 to 240 "
Gummy julep, each	675 "
Syrup of Tolu,	

M. S.: A dessertspoonful every hour or two, according to the child's age.

Creosote and Ichthyol in the Treatment of Pulmonary Tuberculous Disease.—Dr Hugo Goldman (*Wiener klinische Wochenschrift*, 1898, No. 35; *Meinisch-chirurgisches Central-Blatt*, March 17, 1899) gives the following formula, by which, he says, the taste of ichthyol is masked:

R Creosote carbonate, each	15 parts;
Ichthyol,	
Glycerin	30 "
Peppermint water	10 "

M. S.: Twenty drops, gradually increased to thirty (for children, ten to twenty), three times a day, in wine or lemonade, after meals.

* Gibbons. *Ann. Med.*, Edinburgh, 1796, vol. i, pp. 279-305.

|| *The Practice of Surgery*, p. 935 and following.

Elixir of Terpene for Bronchitis.—The *Revue médicale* for March 29th, quoting the *Gazette hebdomadaire de médecine et de chirurgie*, attributes the following to Crinon:

℞ Terpene	150 grains;
Glycerin	2,250 "
Alcohol	2,250 "
Syrup of honey	1,875 "
Tincture of vanilla	150 "

M. From two to four tablespoonfuls daily.

An Ointment for Acute Articular Rheumatism.—The *Settimana medica* for March 25th ascribes this formula to Bourget:

℞ Salicylic acid,	} each	10 parts;
Lanolin,		
Oil of turpentine,		
Lard		80 "

M.

Atropine as a Remedy for Seasickness.—The *Journal de médecine de Paris* for March 26th credits this formula to F. Rebate:

℞ Atropine sulphate	0.045 of a grain;
Distilled water	2½ drachms.

M. A hypodermic syringe-ful to be given every seven or eight hours. Rebate has seen no accidents from its use. In a number of cases he has been able not only to stop the vomiting, but also to allay the disagreeable sensation in the epigastrium.

A Revulsive and Stimulating Embrocation.—The *Progrès médical* for March 25th ascribes the following formula to Huchard:

℞ Tincture of juniper	240 parts;	
Tincture of lavender	120 “	
Oil of turpentine	60 “	
Menthol, {	} each	1 part.
Thymol, {		

M.

Antilactactic Pilules.—The *Gazette hebdomadaire de médecine et de chirurgie* for March 30th gives the following:

℞ Sodium nitrate	150 grains;
Camphor,	} of each.... 60 "
Potassium nitrate,	
Rob of sambucus,	

M.

To make sixty pilules. One to be taken morning and evening. [A rob is "a preparation made from the juice of fruit by evaporating to the consistence of a soft extract, generally with the addition of sugar."—*Foster's Encyclopædic Medical Dictionary*, vol. iv, p. 2721, *sub verbo*.]

Treatment of Syphilitic Alopecia.—Dr. Gaucher (*Journal des praticiens*, April 1st) makes frequent applications to the scalp of the following lotion:

℞ Corrosive sublimate	3 grains;
Chloral hydrate	60 "
Resorcin	30 "
Castor oil	15 "
Alcohol	3,000 "

M.

From three hundred and seventy-five to seven hundred and fifty grains of tincture of cinchona may be used to replace the same amount of alcohol. But the daily application of quinine is apt to temporarily redden the hair.

An Enema for Membranous Enterocolitis.—A formula of Revillon's is thus given in the *Progrès médical* for March 25th:

℞ Quince-seed mucilage	7,500 grains;
Bismuth subnitrate, {	} each ... 150 "
Bismuth salicylate, {	

M. To be administered after the expulsion of an ordinary enema, and retained as long as possible.

For Scabies.—The *Cronica medica* for February 15th says that one or two frictions with the following ointment often suffice to effect a cure:

℞ Naphthaline	1 part;
Lanolin	9 parts.

M.

Methylene Blue in Malaria.—The *Indépendance médicale* for April 5th attributes to Parenski the following:

℞ Methylene blue	15 grains;
Distilled water	150 "

M.

One cubic centimetre (sixteen minims) may be injected daily.

The Treatment of Superficial Burns.—According to the *Gazzetta degli ospedali e delle cliniche* for March 23d, Reclus extols the following ointment:

℞ Iodoform	from 7½ to 15 grains;
Antipyrine, }	} of each 75 "
Boric acid, }	
Vaseline	600 "

M.

Wertheimer applies to burns, especially in children, the following liniment:

℞ Thymol	from 1½ to 2 grains;
Lime-water, {	} of each 1,500 "
Linseed oil, {	

M.

Starr, to allay the pain and prevent the formation of bullæ, applies instantly to a superficial burn the following ointment:

℞ Perchloride of iron	90 grains;
Vaseline	360 "

M.

Haas uses an ointment made by dissolving from a hundred and fifty to three hundred grains of aristol in six hundred grains of lanolin and the same quantity of vaseline.

Landolt and Gyax employ the following formulæ: For burns of the first degree:

℞ Cocaine hydrochloride	22½ grains;	
Vaseline, {	} of each	150 "
Distilled water, {		
Lanolin	45 "	

M.

For those of the second degree:

℞ Cocaine hydrochloride	22½ grains;
Salol	75 "
Vaseline	375 "

M.

And for those of the third degree:

℞ Euphrene	22½ grains;
Olive oil	52½ "
Lanolin	225 "
Vaseline	450 "

M.

This ointment is said to be specially serviceable in burns of the eyelids.

NEW YORK, SATURDAY, APRIL 22, 1899.

BORAX AND BORIC ACID AS PRESERVATIVES OF
FOOD.

THE *National Druggist* has undertaken a searching inquiry into the experience of various authorities in the matter of the alleged harmfulness of these agents, and into the published opinions of writers. The results of its investigation are given in its April issue. Our contemporary has been able to find only one printed article purporting to be in any way authoritative in which the preservatives in question are said, and that by false analogy, to be perhaps injurious to the animal organism. The false analogy in the article, by Peligot, originally published in a secular journal and probably written under the bias of an inclination to help on the trade in refrigerated meats at the expense of the preserved-meat industry, lies in his having inferred from the deleterious action of borax and boric acid on vegetation that they were injurious to animal life, the direct opposite, as our contemporary points out, of the inference he might legitimately have drawn.

This article of Peligot's, perverted by garbled extracts and by ignoring the fact that the experiments had been performed only on plants, served another writer, Le Bon, whose article also was originally published in a French secular journal, and thence translated for the *Chemical News* for January 3, 1879, as the foundation for such sweeping assertions as that all saline preservatives, including common salt, should be avoided, and that refrigeration was the only safe method of preserving meats, etc., to be used as food. One has simply to bear in mind, says the *National Druggist*, that twenty years ago, when Le Bon's article came out, there was a contest going on between persons engaged in handling refrigerated meats from South America and Australia and those engaged in the older processes of preservation.

Our contemporary states that it has been able to find but one report in medical literature of evil consequences ascribed to borax or boric acid, that of Dr. Gower, in the *Lancet* for September 24, 1881, who states that in three cases in which large doses of borax had been given for prolonged periods in the treatment of epilepsy its use had been followed by psoriasis. Granted, says the

Druggist, that the psoriasis was caused by the borax, does not the exclusive use of meats put up with common salt give rise to a much worse disease, scurvy? And, yet, it adds, the use of salt as a food preservative is not forbidden.

On the other hand, the *Druggist* cites many and eminent authorities in testimony to the innocuousness of borax and boric acid as preservatives. In short, our contemporary seems to us to have "blown away," as it phrases it, the last possible objection to the use of these agents for preserving articles of food.

THE FOOD QUESTION IN THE TROPICS.

Now that we have become a power having national interests in the tropics, it may not be amiss to call attention to the fact that much physical harm is done to white residents of tropical regions by their habits of eating overmuch meat and other highly nitrogenous food, and of using alcohol with the same freedom as that to which they are accustomed in their own temperate climates. We can assert from actual experience in many tropical countries, and this is not altogether in accordance with what would naturally be expected, that as soon as the white man becomes settled down after his arrival in tropical regions, the edge of his appetite, instead of being blunted by the heat, is actually sharpened, and he eats a larger quantity of food at breakfast, "tiffin," and dinner than he does at home. The Oriental also eats a large quantity in *bulk*, but in his normal state it is largely vegetable food with a smaller percentage of nitrogen than is contained in the condensed flesh foods used by dwellers in temperate climates. When the native becomes semi-Europeanized, however, he begins to imitate to some extent the white man's usages and to accustom himself to dinners on the European plan, though he frequently keeps a portion of his house organized in native fashion and therein takes some of his meals after native methods.

The *Journal of Tropical Medicine* for March points out very justly the great tendency to diabetes observed among the semi-Europeanized Chinamen in the British possessions in the Orient, and connects it with their adoption of "English chow." As the native is naturally a vegetable feeder, his appetite demands a great bulk of food, and when he adopts the more concentrated foods which he sees in use among those inhabitants of temperate climates who carry their national customs and habits with them, it is a fact that while a comparatively small amount may be all that is requisite for nutrition, it does not suffice to stay the instant demands

of his appetite. The work thrown on the excretory organs, and especially on the liver and kidneys, by this excessive ingestion of nitrogenous material is thus very heavy; and it is small wonder that diseases of the intestinal canal and liver, and also glycosuria, are found to be very prevalent under such circumstances. We have already stated that the white man also will probably find his appetite for bulk of food, as distinguished from the systemic cry for nutriment, increasing; and we venture to sound a warning note that unless he wishes to become the irascible, dyspeptic, liver-troubled person that so many Anglo-Indians are, or a diabetic, as are so many of the semi-Europeanized Chinese, he should limit himself in the more highly nitrogenous foods, and in the use of alcohol, and "fill up" to the demands of his appetite for a "square meal" with rice and other vegetables and fruits.

In making these suggestions for the benefit of individuals likely to be induced to reside in the Orient or the West Indies by the great promotion of intercourse and commerce which our new possessions will inevitably entail, we would add that if these are the dangers into which ignorance may lead the private individual, it behoves us especially to take thought for the soldier, who has not the privilege of selecting his own rations, but is dependent for his food upon what the army regulations allow and cause to be provided for him. The plea for elasticity in respect of the regulations regarding diet, so as to suit varying conditions of climate, etc., has been forcibly urged in an original communication by Dr. Louis L. Seaman, which appeared in the issues of this *Journal* for March 18th and 25th, and we content ourselves in this connection with directing attention thereto.

ILLUMINATING GAS AND EXPLOSIONS.

The president of the American Chemical Society, Professor Charles E. Munroe, made Explosions Caused by Commonly Occurring Substances the title of his address before the recent New York meeting of the society. It is printed in full in the April number of the *Journal of the American Chemical Society*. To a considerable extent it deals with explosions proceeding from the presence of substances not ordinarily treated as explosive. The whole address is well worthy of careful study, although it does not purport to contain anything new. We have not space to consider more than that portion of it which relates to explosions of mixtures of illuminating gas with air.

Illuminating gas such as is supplied to towns is not in itself explosive, as Professor Munroe remarks, and

can not even be ignited save in the presence of a supporter of combustion, such as atmospheric air. These facts were strikingly exemplified during the siege of Paris. The governor of the city, says Professor Munroe, was apprehensive that the gas-holders of La Villette would endanger the fortifications, but he was assured that there was not the slightest risk. A shell pierced the holder at Ivry and lighted the gas. There was a huge jet of flame for eight minutes, the holder sank slowly, and all was over. A shell penetrated a holder at La Villette and burst in the interior, but did not ignite the gas. Another shell entered a holder at Vaugirard, but no ignition followed the occurrence.

As regards the explosion in the Capitol at Washington some months ago, it seems that the gas had been under twice the normal pressure for half an hour before the accident took place, so that it passed through the governor and, being of the specific gravity of 0.601, gradually settled, mixed with air, until it reached the level of some burning jets and exploded.

A HINT TO CORRESPONDENTS.

It not infrequently happens that we receive letters, the nature of which suggests that they are intended for publication, but which we are obliged to ignore because the writers, either from ignorance of, or carelessness as to, editorial requirements, do not conform thereto; and consequently the publication of their letters would entail upon us an amount of additional labor which we do not feel disposed to undertake. As instances of such defects, we may mention the writing upon both sides of the page, which entails considerable additional trouble on either editor or printer; the habit of using abbreviations, which we distinctly object to as leading to ambiguity and the omission of small words, such as pronouns, etc., from sentences, thus rendering them incomplete. Brevity, it is true, is the soul of wit; but it should be exercised in the condensation of thought, and not in the omission of small words which are necessary to the grammatical construction of a sentence. These items have to be corrected in the editorial office, and much unnecessary labor is thereby thrown on the editor; and further, if the letter, as not infrequently happens, is closely written on a small sheet of note paper, it is often impossible to make such corrections legibly without rewriting the entire letter. We trust our readers will bear this in mind.

ACCIDENT ANNUNCIATORS IN PARIS.

THERE are certain persons who never tire of telling us how well oiled the municipal machinery is in Paris. Perhaps the following exception proves the rule: A working girl was run down in the street and seriously injured. She was carried into an apothecary's shop, where "first aid" was rendered, but, as there was no telephone connection with the proper ambulance station, a physician, who happened to be passing, had the kindness to obtain permission to use the private telephone of a commercial firm. After recounting the in-

cident, *Figaro* comments as follows: "We hope that the municipal council will complete its ambulance service as soon as possible by a system of annunciators." The *Gazette médicale de Paris* summarizes *Figaro's* account, and adds: "To judge from this note, one would think that we already had accident annunciators in Paris! They have been voted, it is true, but they will not be placed so long as Dr. A. J. Martin has charge of that service, which he detests above everything!!"

MANILA AND THE PLAGUE.

ACCORDING to reports, the almost annual outbreak of plague in China has already set in at Hongkong. The relations between Hongkong and Manila are very close and intimate, and it will be incumbent upon all concerned to take all necessary precautions, sanitary and otherwise, to prevent an outbreak of the disease among our troops there.

ALBUMINURIA AND LACTATION.

A MOTHER's inability to nurse her child is recognized as a great misfortune; so also is anything that renders it improper for her to do so. Hence it is exceedingly satisfactory to learn that at a recent meeting of the Paris Obstetrical Society (*Progrès médical*, April 1st) Dr. Budin and Dr. Chavanne reported the results of their extensive observations of women who, although they had had albuminuria with their pregnancy and in many instances puerperal eclampsia, nursed their children—satisfactory because it has been held that such women should not undertake lactation. Budin and Chavanne find that the children thrive and that the albuminuria promptly disappears.

"SEROTAXIS" IN DERMATOLOGICAL DIAGNOSIS.

SOLUTIONS of caustic potash, as all dermatologists know, are very effective in overcoming infiltration of the skin, such, for example, as is so prominent a feature in many cases of eczema of long standing. Dr. Adalbert Frickenhaus, of Hamburg (*Monatshfte für praktische Dermatologie*, February 1st; *Indipendence medicale*, April 5th), has formed the theory that potash applications cause a diffusion current of serum to set in toward the skin, and that this current carries with it pathogenic germs that may be lurking in the deeper structures of the integument. In a number of cases of lupus he has been able to detect tubercle bacilli in the serous discharge set up by such applications. He has not, however, found the test of any considerable diagnostic value in leprosy or in trichophytosis, although in the last-named disease potash applications are of great therapeutic use. The solution need not be strong, unless it is desired to remove the horny layer of the epidermis.

THE PLANTAR REFLEX BEFORE BIRTH

THERE may be some practical utility under certain circumstances in examining for the plantar reflex in an unborn child, as is remarked by Dr. Paul Tschier (*Frauenarzt*, February 20th; *Indipendence medicale*, April 5th), who reports a case of placenta previa in which, having pierced the placenta for the purpose of extracting the child through it, he met with such defective dilatation of the cervix uteri as compelled him

to resort to delivery by other means. To ascertain if the child was living, he tickled the sole of one of its feet, and the natural retraction of the foot promptly followed, but this promptness gradually lapsed into tardiness, which was attributed to increasing carbonization of the child's blood under the little delay that was necessary.

LYMPHATISM AND THE OCCURRENCE OF SUDDEN DEATH IN DIPHTHERIA.

Two or three years ago Escherich pointed out that there was a connection between lymphatism and the occurrence of sudden death in diphtheria. Recently one of his pupils, Dr. Moriz Daut (*Jahrbuch für Kinderheilkunde*, 1898; *Archives de médecine des enfants*, April, 1899), has reported some new observations tending to confirm the connection. In twenty-seven cases of diphtheria the larynx and trachea were invaded, but the false membrane was neither thick enough nor extensive enough to cause death by asphyxia. However, sudden death took place in spite of intubation, and was attributed to cardiac atony. The diagnosis of lymphatism rested on such constitutional stigmata as the patient's pasty look, some degree of rickets, moderate enlargement of the spleen, and hypertrophy of the follicles of the base of the tongue and of the pharynx, as well as of various lymphatic glands, sometimes also on dullness due to the thymus gland. The status lymphaticus, Daut thinks, tends not only to lead to sudden death in diphtheria, but also to favor the occurrence of the disease.

THE EXPRESSION TREATMENT OF MASTITIS.

WELL recognized as the value of methodical expression is in cases of mammary engorgement, it is perhaps seldom so sharply exemplified as in a case reported by M. Thévenot at a recent meeting of the Lyons Society of the Medical Sciences (*Lyon médical*, April 2d). On the eleventh day after confinement the temperature, which had thus far been normal, rose to over 103° F. It fell, but rose again on the fifteenth day, this time, nearly to 106°. The left breast was painful and presented nodules of tumidity that gave issue to pus mingled with milk. Methodical expression of the milk ducts was practised for from twenty to twenty-five minutes, and then a moist compressive dressing was applied. The next day expression yielded nothing but milk. A few days later there was a fresh rise of temperature, and the right breast was found swollen, but without lymphangitis. Expression was immediately resorted to, and there was no further pain or fever. Thus, says M. Thévenot, an abscess in each breast was prevented.

A DEVICE FOR INDICATING THE PROXIMAL END OF A RUPTURED PRETHRA.

ONE of the difficulties in an operation for complete rupture of the urethra is that of finding the proximal traumatic aperture. In the *British Medical Journal* for April 8th Dr. M. F. Simon, chief civil medical officer of the Straits Settlements, alludes to this difficulty and mentions a device to which he has resorted successfully in three cases, one, however, that is available only after cystostomy. Through the suprapubic opening a small catheter mounted on a slightly curved stylette is passed down the anterior wall of the bladder and guided into the vesical end of the urethra by means

of a finger in the rectum. The stilette being then withdrawn, the catheter is passed on until its point emerges in the wound in the perinaeum.

THE CITY BOARD OF HEALTH AND THE ANTITOXINE TRADE.

THERE are growing indications that, as we lately said was probable, the board is inclined to desist from selling its products. On Saturday of last week the president of the board listened to the arguments presented by a number of medical men who had been invited to meet him, and is reported to have said to them that he was convinced that the department ought to stop the manufacture of antitoxine, except for its own use or for emergencies.

THE CHICAGO BOARD OF HEALTH.

WE are glad to learn, from the *Journal of the American Medical Association* for April 15th that the mayor of Chicago indicated in his recent (second) inaugural address a proper appreciation of the excellent work that has been done by the board of health of that city, work to which we have often alluded in commendatory terms.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 15, 1899:

DISEASES.	Week ending Apr. 8.		Week ending Apr. 15.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	19	7	8	4
Scarlet fever.....	156	11	227	4
Cerebro-spinal meningitis.....	9	10	0	16
Measles.....	267	14	270	12
Diphtheria.....	185	29	199	39
Croup.....	12	9	15	2
Tuberculosis.....	159	166	202	173
Small-pox.....	2	0	29	0
Chicken-pox.....	21	0	30	0

The American Gastro-enterological Association.—The second annual meeting will be held in Washington, on Tuesday, May 2d, under the presidency of Dr. D. D. Stewart, of Philadelphia. In addition to the president's address, the programme contains the following titles: Further Remarks on Erosions of the Stomach, by Dr. Max Einhorn; Fate of the Digestive Ferments, by Dr. John C. Hemmeter, of Baltimore; An Experimental Study of the Absorption of Strychnine in the Different Sections of the Alimentary Canal of Dogs, by Dr. S. J. Meltzer, of New York; The Abuse of Intragastric Diagnostic and Therapeutic Procedures, by Dr. Morris Manges, of New York; A Case of Dilatation of the Stomach due to Latent Ulcer at the Pylorus. Operation by Halsted; Exhibition of the Patient, by Dr. Julius Friedenwald, of Baltimore; Experiments on Gastric Digestion, by Dr. Fenton B. Turck, of Chicago; The State of the Gastric Secretions in Organic Disease of the Heart, by Dr. Frank H. Murdoch, of Pittsburgh; Gastric Ulcer associated with Anæmia, by Dr. Lewis Brinton, of Philadelphia; Some Remarks on Pylorospasm, by Dr. J. Kaufmann; and A Simple Method in Administering Hydrochloric Acid, by Dr. Charles D. Aaron, of Detroit.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general for the week ending April 15, 1899:

Small-pox—United States.

Mobile, Ala.....	Apr. 1-6.....	3 cases.	
Washington, D. C.....	Apr. 3.....	5 "	
Key West, Fla.....	Mar. 29.....	1 case.	
Chicago, Ill.....	Apr. 7.....	1 "	
Evansville, Ind.....	Mar. 31.....	1 "	
		Total,	17 cases.
New Orleans, La.....	Mar. 26-Apr. 1.....	42 "	2 deaths.
Baltimore, Md.....	Apr. 1-8.....	1 case.	
Newbern, N. C.....	Apr. 6.....	1 "	
Galveston, Texas.....	Apr. 1.....	4 cases.	
Zapata County, Texas.....		Small-pox present.	
Newport News, Va.....	Apr. 2-8.....	13 cases.	
Norfolk, Va.....	Apr. 2-7.....	31 "	
Portsmouth, Va.....	Apr. 1-7.....	9 "	

Small-pox—Foreign.

Hongkong, China.....	Feb. 18-25.....	5 cases,	4 deaths.
London, England.....	Mar. 11-18.....	1 case.	
Athens, Greece.....	Mar. 18-25.....	31 cases,	23 "
Calcutta, India.....	Feb. 25-Mar. 4.....	1 death.	
Madras, India.....	Mar. 4-10.....	1 "	
Chihuahua, Mexico.....	Mar. 18-25.....	1 "	
Mexico, Mexico.....	Mar. 26-Apr. 2.....	2 "	2 deaths.
Moscow, Russia.....	Mar. 11-18.....	24 "	4 "
Odessa, Russia.....	Mar. 18-25.....	1 case.	
St. Petersburg, Russia.....	Mar. 18-25.....	13 cases,	1 death.
Warsaw, Russia.....	Mar. 11-18.....	3 deaths.	
Constantinople, Turkey.....	Mar. 6-13.....	7 "	

Cholera.

Calcutta, India.....	Feb. 25-Mar. 4.....	16 deaths.
----------------------	---------------------	------------

Plague.

Calcutta, India.....	Feb. 25-Mar. 4.....	23 deaths.
Mauritius.....	Feb. 14.....	1 case.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 15th inst., a discussion on cerebro-spinal fever was opened, during which the following papers were presented: The Bacteriology and Demonstration of the Diplococcus Intracerebellaris Meningitidis, by Dr. G. C. Crandall; The Symptoms of Cerebro-spinal Fever, by Dr. Given Campbell; The Diagnosis of Cerebro-spinal Fever, by Dr. Elsworth Smith, Jr.; The Disease in Children, by Dr. E. W. Saunders; The Treatment of Cerebro-spinal Fever, by Dr. H. S. Brookes; The Eye Complications, by Dr. J. Ellis Jennings; and The Ear Complications, by Dr. Max A. Goldstein.

The New York Academy of Medicine.—At a stated meeting, on Thursday evening, the 20th inst., the following papers were presented during the continuation of the discussion on malaria: The Morphology of the Malarial Organism, by Dr. James Ewing; Malarial Nephritis, by Dr. William S. Thayer, of Johns Hopkins University; and Some of the Less Common Effects of Malaria, with Remarks upon the Treatment of Chronic Infection, by the president, Dr. William H. Thomson.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 26th inst., the treatment of nasal stenosis due to deflected septa, with or without thickening of the convex side, will be treated of in a number of short papers by Dr. F. H. Bosworth, Dr. Morris J. Asch, Dr. John O. Roe, of Rochester, Dr. Arthur Watson and Dr. E. Baldwin Gleason, of Philadelphia, and Dr. Henry Beaman Douglass.

At the next meeting of the Section in Obstetrics and

Gynecology, on Thursday evening, the 27th inst., Dr. Grace Peckham Murray will read a paper entitled *The Formative Period of Uterine Fibroids*; Dr. A. H. Goelt will present two cases, one of ectopic-gestation products removed by vaginal section, and the other of a normal appendix vermiformis containing grape-seed removed during oophorectomy; and Dr. H. J. Garrigues will present a case of persistent urachus.

At the next meeting of the Section in Neurology and Psychiatry, on Friday evening, the 28th inst., the following papers will be read: *The Relationship of Latent Tuberculosis to Mental Disorder*, by Dr. E. C. Spitzka; *Exercise Treatment in Tabes Dorsalis*, by Dr. Alfred Wiener; and *Paramyoclonus Multiplex associated with Epilepsy*, by Dr. Pierce Clark. Dr. James J. Walsh will present a case of paralysis agitans sine agitatione.

Two Sides to the Question.—According to the *Medical News* for April 8th, a Minnesota veteran, having given a public testimonial to a patent-medicine firm that its medicine has restored him to perfect health, is now trying to set himself right with the Pension Office, which proposes to take him at his word and cut him off the pension rolls.

The Centennial of the Medical and Chirurgical Faculty of Maryland.—On Tuesday evening, April 25th, there will be an address by the president, Dr. Samuel C. Chew, followed by a reception, and on Wednesday evening Dr. W. W. Keen, of Philadelphia, will give an address on the subject of *The Debt of the Public to the Profession*.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Pathology, on Tuesday evening, the 18th inst., a discussion on the relations between renal elimination and general diseases was opened by Dr. Thomas B. Carpenter, Dr. Henry Ingraham, and Dr. Edmond E. Blaauw.

The Mississippi Valley Medical Association.—We learn that the time of the Chicago meeting has been changed to October 3d to October 6th.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending April 15, 1899:*

BALDWIN, L. B., Surgeon. Ordered to the Key West Naval Station.
BRIGHT, G. A., Medical Director. Detached from the Naval Hospital, Washington, D. C., and ordered home to await orders.
DICKINSON, D., Medical Inspector. Ordered to the Washington Navy Yard for temporary duty at the Naval Hospital.
GATEWOOD, J. D., Surgeon. Detached from the Havana Naval Station and ordered home to await orders.
MARCOU, R. O., Assistant Surgeon. Detached from the Key West Naval Station and ordered to the Havana Naval Station.
PEISSON, R. C., Medical Inspector. Detached from the Naval Hospital, Cavite, Philippine Islands, and ordered to the *Olympia*.
PRICE, A. F., Medical Inspector. Detached from the *Olympia* and ordered home to await orders.
WAGGENER, J. R., Surgeon. Ordered to the *Glacier* for duty in connection with marine battalion, and, on arrival at Manila, is ordered to duty in charge of the Naval Hospital at Cavite.

DIXON, W. S., Medical Inspector. Detached from the Naval Academy and ordered to Washington for duty as a member of the retiring board.

DRAKE, N. H., Surgeon. Ordered to duty as a member of the naval medical examining board, New York.

Du BOSE, W. R., Surgeon. Detached from the Naval Hospital, Brooklyn, and ordered to the Naval Academy.

GAINES, J. H., Surgeon, retired. Granted leave to go abroad for six months from May 6th.

GARTON, W. M., Assistant Surgeon. Detached from the *Supply* and ordered to temporary duty in the hospital, New York.

GRIFFITH, S. H., Surgeon. Detached from duty as a member of the marine examining board, Washington, and ordered to the *Prairie*.

HERNDON, C. G., Surgeon. Detached from the *Prairie* and granted sick leave for two months.

ROSS, J. W., Surgeon, retired. Detached from duty at the Army Hospital, Havana, and ordered home.

SNYDER, J. J., Assistant Surgeon. Detached from the hospital, Newport Naval Station, and ordered to the *Wabash*.

STREETS, T. H., Surgeon. Detached from duty as a member of the naval medical examining board, New York, and ordered to the *Philadelphia* as fleet surgeon.

WAGGENER, J. R., Surgeon. Ordered to San Francisco, California, when the marine battalion is ready for passage to Manila, Philippine Islands.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending April 6, 1899:*

GODFREY, JOHN, Surgeon. Bureau order of March 21, 1899, directing Surgeon Godfrey to proceed to Port Huron, Mich., for special duty, revoked. April 3, 1899.

BANKS, C. E., Surgeon. Detailed as inspector of un-serviceable property in the Hygienic Laboratory, Washington, D. C. March 27, 1899.

PECKHAM, C. T., Surgeon. To proceed to New Orleans, La., for special temporary duty. April 2, 1899.

WHITE, J. H., Surgeon. Relieved from duty at the Immigration Bureau, New York, N. Y., and directed to report at Washington, D. C., for duty. April 1, 1899.

McINTOSH, W. P., Passed Assistant Surgeon. Relieved from duty in Hygienic Laboratory, Washington, D. C., and upon completion of duties as recorder of the Board of Examiners at New York, N. Y., to rejoin station at Louisville, Ky. March 25, 1899.

MAGPHER, G. M., Passed Assistant Surgeon. To proceed without delay to Port Tampa, Fla., and await orders. April 2, 1899.

WERTENBAKER, C. P., Passed Assistant Surgeon. To report at bureau for special duty. April 4, 1899.

NYDERGER, J. A., Passed Assistant Surgeon. To proceed to Wilmington, N. C., for special temporary duty. April 5, 1899.

THOMAS, A. R., Assistant Surgeon. Upon completion of examination to determine fitness for promotion, to proceed to the Tortugas Quarantine Station and assume command of service. March 30, 1899.

CRAMMING, H. S., Assistant Surgeon. Upon completion of examination to determine fitness for promotion, to proceed to the Cape Charles Quarantine and re-

port to the medical officer in command for duty. March 30, 1899.

VON EZDORF, R. H., Assistant Surgeon. To inspect un-serviceable property at the South Atlantic Quarantine Station. April 3, 1899.

ANDERSON, J. F., Assistant Surgeon. Granted leave of absence for thirty days on account of sickness. March 31, 1899.

CORPUS, G. M., Assistant Surgeon. To proceed to Mullet Key, Fla., for special temporary duty. March 27, 1899.

DUDLEY, D. E., Sanitary Inspector. To report to medical officer in temporary charge of the Tortugas Quarantine Station for special temporary duty. March 31, 1899.

SCOTT, E. B., Hospital Steward. To proceed to Savannah, Ga., for special temporary duty. March 24, 1899.

Promotion.

Passed Assistant Surgeon L. L. WILLIAMS commissioned as surgeon. March 30, 1899.

Appointment.

DE KRAFFT, S. C., reappointed acting assistant surgeon, M. H. S., for duty at the port of Cambridge, Md. April 1, 1899.

Appointment Revoked.

Department letter of March 11, 1899, appointing OLIVER STEWART acting assistant surgeon at Port Huron, Mich., revoked. April 4, 1899.

Resignation.

Acting Assistant Surgeon MYRON NORTHRUP, resigned, to take effect March 31, 1899. April 4, 1899.

Society Meetings for the Coming Week:

MONDAY, April 24th: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, April 25th: Medical and Chirurgical Faculty of Maryland (first day—Baltimore); New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Rome, N. Y., Medical Society; Medical Society of the County of Putnam, N. Y. (annual); Boston Society of Medical Sciences (private); Hunterdon, N. J., County Medical Society (Flemington); Litchfield, Connecticut, County Medical Society (semiannual); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, April 26th: Medical and Chirurgical Faculty of Maryland (second day); New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Middlesex, Massachusetts, North District Medical Society (annual—Lowell); Gloucester, N. J., County Medical Society (quarterly); Philadelphia County Medical Society.

THURSDAY, April 27th: Medical and Chirurgical Faculty of Maryland (third day); New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurol-

ogy; Roxbury, Massachusetts, Society for Medical Improvement (annual); Pathological Society of Philadelphia (conversational).

FRIDAY, April 28th: New York Clinical Society (private—annual); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

Births, Marriages, and Deaths.

Married.

COHEN—ROTHSCHILD.—In Hamburg, Germany, on Tuesday, April 4th, Dr. Joseph Cohen, of New York, and Miss Golda Rothschild.

COOK—HAIGHT.—In Fayetteville, North Carolina, on Wednesday, April 12th, Mr. Howard Martin Cook and Miss Rebecca Devereux Haight, daughter of Dr. Thomas Devereux Haight.

HOWE—COOPER.—In Westfield, N. J., on Wednesday, April 12th, Dr. William G. Howe, of New York, and Miss Mary G. Cooper, daughter of Dr. Sherman Cooper.

HUNTER—DICKSON.—In Louisville, Kentucky, on Wednesday, April 12th, Dr. Dwight Williams Hunter, of New York, and Mrs. Margaret Donigan Dickson.

OBERLIN—WOLFF.—In Mansfield, Ohio, on Wednesday, April 12th, Dr. Thomas William Oberlin, of Hammond, Indiana, and Miss Duer Lenore Wolff.

POWELL—FEITNER.—In New York, on Wednesday, April 12th, Mr. Irwin Augustus Powell, son of Dr. Seneca D. Powell, and Miss Marie Sidney Feitner.

QUINTON—BROOKS.—In Rutland, Vermont, on Tuesday, April 11th, Dr. W. W. Quinton, United States Army, and Miss Pauline Brooks.

SEDGWICK—HUDSON.—In Boston, on Tuesday, April 11th, Dr. William R. Sedgwick and Miss Vianna Hudson.

SMITH—BOULIGNY.—In New Orleans, on Saturday, April 15th, Dr. Augustin J. Smith, of Franklin, Louisiana, and Miss Marie Bouligny.

SOMERS—GREELEY.—In Ogdensburgh, N. Y., on Wednesday, April 12th, Dr. Elbert Mortimer Somers, Jr., and Miss Harriet Gilbert Greeley.

WEEKS—AHERN.—In New York, on Monday, April 17th, Dr. Charles Louis Weeks and Miss Lavinia Ahern.

Died.

EVERETT.—In Middletown, N. Y., on Sunday, April 9th, Dr. Harvey Everett, aged eighty-eight years.

GIBSON.—In Colorado Springs, Colorado, on Monday, April 10th, Dr. James B. Gibson, aged thirty-five years.

KITTREDGE.—In Salem, Massachusetts, on Monday, April 10th, Cornelia L. Kittredge, wife of Dr. Thomas Kittredge.

LAFFERTY.—In Richmond, Virginia, on Monday, April 10th, Dr. Walter B. Lafferty, of Crozet, Virginia.

LOUGHAN.—In Kingston, N. Y., on Tuesday, April 11th, Dr. Robert Loughan, in the sixty-fourth year of his age.

MCDONALD.—In Shiremanstown, Pennsylvania, on Tuesday, April 11th, Dr. David L. McDonald, aged fifty-seven years.

PAYNE.—In Poughkeepsie, N. Y., Dr. John Chester Payne, in the eightieth year of his age.

Letters to the Editor.

KERNIG'S SIGN IN THE DIAGNOSIS OF MENINGITIS.

27 WEST ONE HUNDRED AND FIFTEENTH STREET,
NEW YORK, April 15, 1899.

To the Editor of the New York Medical Journal:

SIR: In to-day's number of your *Journal* I find a short notice on Kernig's Sign in the Diagnosis of Meningitis. Henoch, in his work on *Diseases of Children* (German edition of 1895), says that this symptom is not pathognomonic, since it was absent in a very severe case in which the diagnosis was corroborated by autopsy; also that it may be present in other cerebral diseases. He states that this phenomenon is also present to some extent in healthy persons, especially when the trunk is bent slightly forward, making an acute angle with the thigh. Any one can test this for himself.

As for the explanation of this phenomenon, the three long flexors of the knee which have their origin at the tuber ischii (semitendinosus, semimembranosus, and biceps) are highly tense and contain very many short fibres. Such a stretching as a simultaneous flexion at the hip and extension at the knee would render necessary is impossible. In the cadaver, also, this can not be done.

In meningitis, owing to the increased "tonus," the muscular resistance is still greater than in the healthy state.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XV.

RIGHTS AND LIABILITIES OF THIRD PARTIES.

(Continued from page 558.)

Rights of Third Parties.—Having examined those cases in which third parties are liable to both the physician and patient, we will now pass to a consideration of the rights of third parties.

Rights of Husband.—It has been observed that the husband is subject to certain liabilities arising from the treatment of his wife; it is therefore natural to suppose that he has certain rights in the premises which should be respected.

In case it becomes necessary to operate upon a patient, is it necessary to first obtain consent from her husband? In the case of *McClallen vs. Adams*, a husband placed his wife under the care of a physician whom he knew, at a distance from his own residence, for treatment for a scrofulous tumor of the breast; while the wife was under the doctor's care a cancerous condition developed, and the physician without the husband's knowledge amputated the breast, from which operation

the patient never recovered. The court was of the opinion that the husband, in placing his wife in the care of the physician under the circumstances stated, "impliedly requested him to do all such acts, and adopt such course of treatment and operations, as in his judgment would be most likely to effect her ultimate cure and recovery, with the assent of the wife, and therefore that the operation in question was within the scope of the authority given him." The court, commenting upon the case, further said: "Although it might have been an act of prudence in the [physician] to give the [husband] notice of the situation of the wife, and of his intention to perform a dangerous operation, yet we think he might safely trust to the judgment of the wife, to give her husband notice from time to time of her situation and intentions, and that it was not necessary, in point of law, for the [physician] to give such notice, or to have any new request or authority."*

The court, in the case of *State, etc., vs. Housekeeper et al.*, decided in 1888, in considering a similar state of facts, said: "The consent of the wife, not that of the husband, was necessary. The professional men whom she had called in and consulted were the proper persons to determine what ought to be done. They could not, of course, compel her to submit to an operation, but if she voluntarily submitted to its performance, her consent will be presumed, unless she was the victim of a false and fraudulent misrepresentation, which is a material fact to be established by proof." In this case the evidence showed that the wife had been afflicted with a lump in her right breast, supposed to be an innocent tumor, but afterward ascertained to be a cancer. The physicians operated for cancer, removing the entire breast. The husband testified that he supposed the operation was for the purpose of removing a tumor, and that he would never have consented to the operation which was performed. The evidence did not show whether the wife was informed of the character of the operation to be performed, but the court stated the law relative to this question as follows: "The party who allows a surgical operation to be performed is presumed to have employed the surgeon for that particular purpose."†

It is a rule as old as the common law itself that the husband is entitled to the society and services of his wife; if, therefore, the physician, through improper care or inattention, prolongs the sickness of the wife, he can be held to respond in damages to the husband for the value of his wife's society and services during such period of prolonged sickness, also for the expense he is put to in caring for her during this period.‡

And, finally, when the wife dies, the husband is entitled to have her body in the condition in which the breath leaves it for the purpose of interment. Should the physician violate this right and perform an autopsy upon the body without the consent of the husband, it seems well settled that he can be held to respond in damages to the husband; the amount of damages would be assessed by the jury, and the principal element upon which it would be based would be the injury to the husband's feelings.§

This right to the body of the deceased is primarily

* *McClallen vs. Adams*, 19 Pick. 3.

† *State, etc., vs. Housekeeper et al.*, 21 Me. 107, 16 Vt. Rep. 388.

‡ *Stevon vs. Tullman*, 50 Ill. App. 2, 1897; 100 Ill. 371, 37 Minn. 513, 70 N. W. 140.

§ *Foley vs. Phelps*, 57 N. Y. Supp. 431, 1 App. Div. 351.

in the surviving husband or wife; if there is no surviving husband or wife it is in the next of kin.*

Thus a father who places his child in the care of a physician has the right to immediate possession of the body upon the child's death, and can maintain an action against the physician for any violation of this right.†

This proposition is, of course, to be understood with the qualification that, where the circumstances of the death are such as to render a coroner's inquest necessary, the physician who performs the autopsy under the coroner's orders is protected in so doing if he treats the body with ordinary decency and does not wantonly or unnecessarily disfigure it.‡

It has been observed that the doctor's duty requires him to sometimes destroy property which is infected with any contagious disease; but when such property belongs to third parties, have they any recourse against the physician who ordered its destruction?

A case occurred in Maine in 1874 in which the owner of a house in which small-pox patients had been, sued the physician for ordering the paper removed from the wall, the plaintiff claiming that its removal was not necessary to properly disinfect. The trial court gave the plaintiff a judgment of thirty-five dollars against the physician, but the supreme court sent the case back with an opinion of law which relieved the physician from all liability in the premises. In this case the court, speaking through Justice Walton, said: "When the small-pox or any other contagious disease exists in any town or city the law demands the utmost vigilance to prevent its spread. . . .

"To accomplish this object, persons may be seized and restrained of their liberty or ordered to leave the State; private houses may be converted into hospitals and made subject to hospital regulations; buildings may be broken open and infected articles seized and destroyed, and many other things done which, under ordinary circumstances, would be considered a gross outrage upon the rights of persons and property. This is allowed upon the same principle that houses are allowed to be torn down to stop a conflagration. *Salus populi est suprema lex*—the safety of the people is the supreme law—is the governing principle in this case.

"Where the public health and human life are concerned the law requires the highest degree of care. It will not allow of experiments to see if a less degree of care will not answer. The keeper of a furious dog or mad bull is not allowed to let them go at large to see whether they will bite or gore his neighbor's children . . . nor is one using a steam engine to see how much steam he can possibly put on without bursting the boiler. No more are those in charge of small-pox patients allowed to experiment to see how little cleansing will answer; how much paper spit upon and bedaubed with small-pox virus it will do to leave upon the walls of the rooms where the patients have been confined. The law will not tolerate such experiments. It demands the exercise of all possible care. In all cases of doubt the safest course should be pursued, remembering that it is infinitely better to do too much than to run the risk of doing too little."

It will seem conclusive after reading this forcible opinion that third parties have no right whatever to interfere with the physician in taking such reasonable steps as he deems necessary for perfect disinfection, and

that he can only be held responsible for or restrained from wholly unnecessary or willful destruction.

A peculiar case touching the liability of a physician to a third party recently arose in Massachusetts. A physician was employed by a father to examine a young man, who was engaged to be married to his daughter, to determine whether or not he was affected with a venereal disease. The young man had accidentally injured himself, and the physician, after making the examination, reported that he was suffering from gonorrhoea, by virtue of which statement the engagement was broken off.

The injured man sued the physician, and the supreme court held that if he did not possess ordinary skill and learning, and use ordinary diligence and care in their exercise, he was liable to the plaintiff, and that the breaking of the plaintiff's marriage engagement in consequence of the wrong diagnosis was not too remote a damage to sustain the action.* Whether or not he did possess ordinary skill and learning and exercise proper care and skill in conducting the examination, was a question for the jury to determine from the evidence adduced at the trial.

Pith of Current Literature.

Hygienic Underclothing.—Dr. Thoma, of Berlin (*Therapist*, March 15th), recommends underclothing made up in a double layer—the inner layer, or that nearest the skin, being ribbed so as to contain between the ribs a large quantity of air; the outer layer being smooth, plain, and very porous. There is thus a continuous but gradual interchange between the external air and that in contact with the surface of the body, so preventing sudden cooling. Wool he considers an unhygienic material to wear next the skin. On this point he observes that persons who wear woollen underclothing for the first time complain of itching, which disappears by degrees, and after some months no unpleasantness of any kind is noticed. If we, however, examine the sensitiveness of the skin of a person who has worn woollen underclothing for years, we find that slight electric currents are no longer felt, while others who have always worn cotton or linen underclothing can feel these currents very distinctly. The sensitiveness of the nerves of the skin, therefore, is reduced by the continuous irritation of the wool, and becomes deadened. The degree of sensitiveness of the peripheral nerves, however, affects reflex action, upon which depend the contraction and dilatation of the smallest vessels, which is equivalent to the action of the skin.

Woollen underclothing, therefore, if covering the skin *directly*, reduces the action of the skin *indirectly*, thereby diminishing the resistant power of the body to external influences of temperature.

Cotton absorbs perspiration too slowly and conducts heat too well, while linen allows perspiration to evaporate too quickly, causing chills. The material he recommends consists of a ribbed inner layer of cotton from which the oil has previously been extracted, and which does not absorb the perspiration; and an outer layer of wood wool around which a thread of cotton (from both of which the oil has also been extracted) has been spun, thereby preventing any shrinking of the outer layer when washed. This hygroscopic outer layer receives the

perspiration of the body, in the form of vapor, thus keeping the inner layer dry. The disadvantage of cotton—viz., its non-absorbent property—he considers of real advantage to the underclothing he recommends, and the hygroscopic wool does not come in contact with the body.

Nephritis from a Medico-legal Point of View.—Dr. Harold N. Moyer (*Journal of the American Medical Association* for March 25th), at the Chicago Academy of Medicine on February 28th, called attention especially to two legal relations which the kidneys had, and which, he said, were not referred to in the books. The first dealt with the possibility of an injury to the kidney, shown by the presence of blood sometimes, by the presence of albumin always, and sometimes by casts in the urine. He had met with three such cases which were subjects of medico-legal inquiry, the parties having brought suit in consequence of the injuries. Among the symptoms of those cases were the points just named. One case longer under observation than the others was that of a man injured by being run over. A heavy wagon had passed over the loins, and together with some rather insignificant nervous symptoms he presented a copious hematuria, followed by albuminuria and casts in the urine. This lasted for some weeks. There were no vascular changes, and prior to the accident in question the man had always been well. He made a perfect recovery. Dr. Moyer examined his urine at intervals for two years following the injury. He believed that the patient had sustained a serious injury to the kidney, which produced albuminuria and casts, and which subsequently cleared up. He had seen two similar cases, but they had not been so well studied. It was possible that injuries of the kidney might have a medico-legal interest in a case of ordinary damage suit.

The other point to which he would specially direct attention was uræmia. We might have uræmia without appreciable alteration in the kidneys. He believed that it was responsible for some cases of sudden death. Cases were met with by those who made examinations of dead bodies to ascertain the cause of death for medico-legal purposes in which absolutely no change could be found in any of the vital organs—the brain, heart, lungs, and kidneys were seemingly normal. Death by the heart or by the brain almost always left distinct traces that could be seen post mortem. He had believed for some time that uræmia explained some of the peculiar and by no means rare, cases. The experimental data which had been accumulated regarding the relation of the kidneys could not be explained on any other theory than that in uræmia we had an exceedingly complex poison, not necessarily one that failed to be eliminated by the kidney. These symptoms might gradually appear from some disturbance in the metabolism of the tissues or of the vital organs other than the kidneys, and present identical symptoms with those that followed advanced kidney disease. He believed some of the cases of sudden death attended by coma were explainable in this way. The subject was an important one from a forensic standpoint.

A Singular Tubal Pregnancy. M. Pollosson (*Revue médicale de Lyon*, March 7th) reported recently to the Medical Society of Lyons the case of a woman, aged one year of age, who had previously had four pregnancies advancing to term. There were no signs referable to the uterus or annexa. In fact, no signs

logical symptoms. The pregnancy was presumably advanced about six weeks. The patient suffered from intractable vomiting, and but for the normal pulse M. Pollosson would have practised abortion at once. After some weeks of ineffectual medication he proceeded to perform abortion. Dilating the uterus with Hegar's bougies, he found the abdomen supple, and bimanual examination discovered a tumor of the size of an orange in the pelvis. The cervix uteri seemed to depend from this tumor, which was naturally supposed to be the body of the uterus. When dilatation was complete, M. Pollosson inserted his finger into the uterus and found it empty. Passing the finger forward, he found an opening beyond the cervix, into which he introduced his finger, wondering whether it connected with the peritoneum or bladder. A sound passed into the bladder proved the latter to be intact. There was a pouch in front of the uterus, above the neck and external to the peritoneum, from which he extracted a fetus as long as his finger with a head of about the size of a nut, and its placenta. The uterus and the cavity were plugged with iodoform gauze, and the patient made an uneventful recovery. Extra-uterine gestation sacs are usually situated either laterally or in the posterior cul-de-sac, though Pinard states that he has seen a case where the seat was anterior.

The Removal of the Uterus for Placenta Prævia.—Lawson Tait (*Lancet*, February 25th; *American Journal of Obstetrics and Diseases of Women and Children*, March), after considering the mortality consequent upon "unavoidable hæmorrhage," says that one aspect from which it is extremely interesting is that it is one of the few points in the practice of surgery where our conduct may be influenced by ecclesiastical authority. The Church of Rome rules that in such a case the living birth of the child is all-important, and when the interests of mother and child conflict those of the former must yield. In one case to which he was called by the late Dr. Wynne Thomas this decision, arrived at by the mother and the father of the child, as advised by their spiritual directors, seemed to the doctor to cost the mother her life, though it did save the child. Under such circumstances that part of the treatment directed against the immediate risk from hæmorrhage has its influence for good directly contravened, and probably entirely annulled, by the causes introduced and the risks produced of secondary mortality. All these conditions existed in a case to which he was called on December 21, 1898, by Dr. Herbert Simpson, of Rugby. The patient was young and slightly built, and had as bad a history of hæmorrhage as a woman well could have. She had always had "something wrong" inside and had been a regular consumer of ergot for years. She had been twice cured and cauterized. She had nearly lost her life from postpartum hæmorrhage in her second confinement, had had several miscarriages with severe losses, and he found her in great distress and faint at the full time with a cervix dilated to the third finger and amniotic fluid off, the uterus being very large, over the child, and yet she had been feeling well and in good condition for five hours, in spite of many attempts at a dozen points of treatment which Dr. Simpson had employed. The child was easily extracted and alive, and the condition of the placenta was such that that of the mother was not put in jeopardy. But he confesses that the result of the case was such as made him hesitate to do what he had been told to do.

forcefully dilate the cervix and extract the placenta, whether he followed that by version or not, whether or not he left the after-labor to Nature and the child to its fate. An alternative occurred to him to which he was prompted by the splendid success which has followed it in his hands and in those of others under different yet very analogous circumstances—viz., removal of the uterus. It had many arguments in its favor: it would save the child, it probably would save the mother, and it would relieve her of the condition of perpetual misery and risk in which she had been living for years, and would therefore assist her in properly rearing the children she had, rather than in tending to procreate others to whom she certainly showed no likelihood of ever being able to give proper care. There were no arguments against it except the familiar one of "mutilation." As he had already characterized that as the argument of the brothel-keeper rather than one for the consideration of the physician, he attached little importance to it. Putting himself in the place of the patient's husband, so far as he could, he felt that the Church of Rome had some reason for its decision, though more as a matter of right than of salvation—that any proceeding which would diminish the mother's risk from fifty per cent. or forty per cent., or even twenty per cent., to four or five per cent., must be selected. Finally, the argument would have been overwhelming to him as a husband that his wife would have health and comfort for her after-life, instead of misery and risk, irrespective of sterility or mutilation or anything else. He therefore proposed hysterectomy, and after full discussion it was accepted by Dr. Simpson, by the husband, and by the patient. He performed it with the aid of the elastic ligature, by the operation known in America as the "Tait-Porro" operation. The patient made a straightforward recovery, interrupted only by occasional rectal distention. A fine female child was born alive and lived for a month, succumbing, unfortunately, a month after birth, when the cold weather distributed bronchitis. This case forms, so far as he knows, a new departure. Whether it will receive a universal commendation is not the least a matter of doubt. The "mutilationists" will raise their voices against his proposal, but there are others who will follow his example, and to those who do this will surely come the comfort that they will diminish "the anxiety to the practitioner and the real danger to the patient" of the obstetric difficulty which Simpson so graphically tells us has more of both than any other.

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of December 7, 1898.

The President, Dr. S. ALEXANDER, in the Chair.

(Concluded from page 574.)

Logical Analysis in Therapeutics. This was the title of a paper read by Dr. CHARLES E. QUIMBY. (See page 553.)

Dr. EGLETT LE FEVRE said that the paper presented a very clear outline of the fallacies of therapeutics, yet we should not be discouraged, even though we did not

always practise what we preached. Our conceptions of the aetiology of disease had changed so much during the past fifteen years that it was rather a matter of surprise that there had not been more confusion. The lagging of our therapeutics seemed to him to be rather helpful than otherwise. Until the physiological action of drugs had come to the fore with a newer physiology our knowledge of drugs was almost entirely empirical. In animal experimentation was to be found a rational basis for our medication. But we had now another matter to consider—i. e., the question of intoxication in disease. In using the coal-tar products the profession had been running after strange gods. The cause for such heresies was not to be found entirely in the wrong teaching of *matéria medica*. The day of dogmatism had gone by, and the teacher must state candidly that many points remained yet to be cleared up. This allowed the young graduates to go forth with their minds rather too open, and, as a result, they became easy victims of the venders of new medicines.

He agreed to what had been said regarding the abuse of strychnine and the loose way in which it had been administered. He was not willing, however, to go so far as the reader of the paper regarding oxygen. He knew of no physiological experiments or chemical data which would lead us to think that by giving oxygen in the manner indicated in the paper one might expect the much-desired systemic improvement. He had personally been much disappointed in the use of oxygen, particularly in pneumonia. Certainly there was a certain degree of elimination by the lungs, but in diseased conditions, such as pneumonia, in which oxygen was indicated, he doubted if the lung could be sufficiently stimulated to eliminate the gas.

Dr. BRILL said that the profession was becoming nihilistic in its use of drugs, and this was not to be wondered at when it was remembered that the treatment of disease, with few exceptions, was directed toward certain symptoms characteristic of the morbid process to be treated. It was true that medical students were taught the physiological action of drugs, and went out of college with such stimulants as caffeine, strychnine, digitalis, and alcohol, but when they were confronted with disease they were not always able to recognize the necessity for the treatment directed toward the prominent symptoms—for instance, in pneumonia, the prime necessity was to keep up the proper action of the heart. Some used one of these cardiac stimulants alone, and the result being good, this drug alone was used for a long time afterward. When, at last, a patient did not do well, they tried another remedy, and eventually they reached the state of mind in which they believed that there were no good cardiac stimulants—from being therapeutic enthusiasts on leaving college they came to be therapeutic nihilists. All drugs used should be thoroughly tested, and their physiological effects carefully studied and made clear before these remedies were presented to the profession.

Dr. QUIMBY said that in his paper he had desired above all things to disclaim any thought of dogmatism, and that he did not believe an examination of all his published writings would reveal any justification for such an accusation. The statements in the present paper, which had been called dogmatic, were given as logical deductions from accepted data. The logic by which they had been obtained was open to the most rigid criticism, but, however defective or fallacious that might be, it still eliminated all dogmatism. The

later physiology and systemic intoxication as the dominant factor of disease from specific causes, to which reference had been made, had been the fundamental facts upon which he had relied for justification of his paper, since they showed with such perfect clearness not only the beautiful possibilities, the consequent necessity of scientific analysis of pathic process, but drug actions and their antagonistic relations in therapeutics. The expressed disappointment of one of the speakers in the use of oxygen added further support to his position, and of itself justified any honest effort to discover a logical method of the use of that gas. What had been presented was simply the result of such an effort. He desired to express his indebtedness for the interest manifested in the subject.

Book Notices.

Respiratory Exercises in the Treatment of Disease.

Notably of the Heart, Lungs, Nervous and Digestive Systems. By HARRY CAMPBELL, M. D., B. S. Lond., Fellow of the Royal College of Physicians, London, etc. New York: William Wood & Co., 1899. Pp. viii-200.

THE author discusses in the first twenty chapters some of the many physiological problems connected with the mechanism of respiration and the effects of respiratory movements on the circulation and the bodily nutrition. Then the modifications of the respiratory act are taken up and discussed at some length, together with the value of singing and talking as pulmonary gymnastics, and finally, in the last fifty pages, Dr. Campbell turns to the medical consideration of regular, methodical breathing exercises as a method of preventing and in some cases curing pulmonary lesions. These exercises are also to be used, according to the author, in cardiac disease and in disorders of the digestive and nervous systems. The whole discussion of the subject savors rather more of much reading than of actual clinical experience, yet there is much that is suggestive even if not absolutely new, and the style of presentation is clear and attractive.

Die Fremdkörper des Uterus. Zusammenstellung von 550 Beobachtungen aus der Literatur und Praxis. Von Dr. FRANZ L. NEUGIRARER, Vorstand der gynaekologischen Klinik des Evang. Hospitals in Warschau. Zweite Ausgabe. Berlin: S. Karger, 1899. Pp. 111.

THE author has collected in this brochure most of the reported cases of foreign bodies found in the uterine cavity. This title, however, is somewhat misleading, as the collection includes also cases of ectoparasites, some of the uterus, those of substances which may enter the uterine cavity by means of isthmus or by tearing of the course of delivery, and also those of prolonged retention of the fetus in the uterus. Seven cases are given of mummies removed from the uterus which contained fetuses; they probably originated from the rupture of ovarian dermoids into the uterine cavity. Beyond the reports of the findings the author does not go; there is no attempt at anything more than a compilation of the work of others, with the addition of a few important personal cases.

An Experimental Research into Surgical Shock. An Essay awarded the Cartwright Prize for 1897. By GEORGE W. CRILE, A. M., M. D., Ph. D., Professor of the Principles of Surgery and Applied Anatomy in the Cleveland College of Physicians and Surgeons, etc. Philadelphia: J. B. Lippincott Company, 1899. Pp. 5 to 160. [Price, \$2.50.]

THIS essay embodies the results obtained by a long series of experiments on animals to determine, if possible, the anatomical basis of surgical shock. A number of valuable points were observed, bearing chiefly on the value of the methods now in use for the combating of shock as seen clinically. Saline infusions, strychnine, heat, and an inverted posture were found experimentally to relieve most rapidly and surely the condition of low arterial pressure characteristic of shock.

Suprarenal extract was of no value, the initial rise being rapidly followed by a fall. Artificial respiration was useful in many cases. The cause of the condition known as shock was found to be an impairment or breakdown of the vasomotor mechanism, a view long ago advanced by Goltz and since adopted by most writers on surgery.

Les rayons de Röntgen et le diagnostic de la tuberculose. Par A. BÉCLÈRE, Médecin de l'Hôpital Saint-Antoine. Avec 9 figures dans le texte. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 95.

THE author is quite conservative in his opinions on the possibility of the diagnosis of pulmonary tuberculosis by means of the Röntgen rays, and brings out very clearly the fact that shadows and dark patches are quite often seen in the lungs of persons in excellent health. The great advantage of the rays lies in the fact that consolidation in the centre of a lobe can be seen before it can be made out by percussion, but in all cases the final appeal must be made to the bacteriological examination of the sputum or the cautious use of tuberculin. M. Bécère insists strongly on the fact that the person who is to make the fluoroscopic examination should remain for some time previous in a dark room, as his vision by this simple means is rendered vastly more acute than if he comes from a brightly lighted room.

Holden's Human Osteology: Comprising a Description of the Bones, with Delineations of the Attachments of the Muscles, the General and Microscopic Structure of Bone, and its Development. Edited by CHARLES STEWART, F. R. S., Hunterian Professor of Comparative Anatomy and Physiology, Royal College of Surgeons of England, etc., and R. W. RICH, M. D., F. R. C. S., Regius Professor of Anatomy in the University of Aberdeen. Fourth Edition. London: J. & A. Churchill, 1899. Pp. ix, 358. [Price, \$5.25.]

IN the preface the editor states that revisions have been made in order to bring the book up to the present state of our knowledge. It was, however, a textbook should retain its popularity, and its general conditions and for so long a time, that it would not be changed to suit modern ideas and methods. As the bones have not changed, the revisions have undergone considerable improvement. We can only say that this book is up to the standard of the best recent works on anatomy. It embodies a most excellent description of the bones in general, not only, for instance, should the old description of the thoracic bone be per-

petuated any longer—a description which is most difficult to learn and which in the end gives us no idea of the construction of the bone? The aurist simply has to learn it over again.

The fact is, we are suffering from the popularity of some of our old text-books. They do not need additions, but excisions and complete revision.

The volume before us is printed in handsome type on excellent paper. The cuts, which must have been once a feature of the book, now seem antiquated.

Atlas der Syphilis und syphilisähnlichen Hautkrankheiten für Studierende und Aerzte. Von Dr. med. MARTIN CHOTZEN, Spezialarzt für Hautkrankheiten in Breslau. Heft XI. Pp. 135 to 145. Heft XII. Pp. 147 to 161. Hamburg und Leipzig: Leopold Voss, 1898.

THESE two numbers complete the atlas, of which the previous parts, I to X, have already been reviewed. In these are both colored and uncolored plates. Of the latter, No. 64, No. 65, No. 67, No. 68, and No. 73 are very good, representing perioritis ossium narium, etc. Colored plate No. 70, dealing with the larynx and eye, is also to be praised, but in regard to most of the others the same statements made in previous notices are pertinent. The text accompanying the plates gives the clinical history and treatment of each case from which a drawing was made, and is a very useful feature. A list of various diseases represented in the *Atlas* and a full index complete the work, which pictorially is probably as good as could be expected in view of its low price.

Diseases of the Skin: An Outline of the Principles and Practice of Dermatology. By MALCOLM MORRIS, Surgeon to the Skin Department, St. Mary's Hospital, London, etc. With Ten Colored Plates and Twenty-six Engravings. New and Revised Edition. Philadelphia: Lea Brothers & Co., 1898. Pp. xv-589. [Price, \$3.25.]

IT is with pleasure that Dr. Morris's book is recommended to the profession, though the recommendation given pertains entirely to the text, and certainly not to the colored plates which accompany it. Beginning with general remarks on the pathology of the skin, the author then takes up the classification of skin diseases, which, he truthfully says, is a good servant but a bad master. Unquestionably no greater harm can occur to a dermatologist in the present state of our knowledge than attachment to a classified system of skin diseases, into which *volens volens* each example which comes along is crammed.

Nothing new is found in the chapter devoted to principles of diagnosis, but in dealing with the subject of dermatology it is the manner in which the symptoms, etc., of each cutaneous disease are put, it is the clearness and earnestness of expression characteristic of the observer that make the charm of the book, and causes it to be recognized as the work of one who is well known to be among the very foremost dermatologists of England.

No particular portion of the book can be especially referred to for its superiority, but the whole work is worthy of careful reading. More, for instance, than in any other treatise on cutaneous disease, do we find the rôle of the proœmic organism considered. Categorical statements are not made, nothing absolute is advanced, but the suggestion derived from bacteriological study

and investigations are given and their possible and probable connection with skin diseases is brought forward. Furthermore, in Morris's book it is a relief to find eczema treated particularly upon the basis of its etiology and pathology, and not to come across the time-hallowed eczema vesiculosum, eczema pustulosum, eczema madidans, eczema rubrum, etc., laid out on paper like parterres in a flower garden, regardless of the origin, course, or any other factor active or existing in the production of the disease.

Frankly and heartily can Dr. Morris's book be recommended, and it is to be hoped that such works will replace in the hands of the student the compendiums appearing on all hands, which, like all other short cuts to knowledge, give only a simulacrum of the subject, and are not really satisfactory.

Lectures on Appendicitis and Notes on other Subjects.

By ROBERT T. MORRIS, A. M., M. D., Adjunct Professor of Surgery in the New York Post-graduate Medical School and Hospital, etc. Third Edition, revised and enlarged. With Illustrations by HENRY MACDONALD, M. D. London and New York: G. P. Putnam's Sons, 1899. Pp. x-185. [Price, \$2.]

THE appearance of a third edition shows the demand which exists for works of this character and scope. Many new and valuable ideas have been introduced, including some interesting correspondence from patients. The illustrations are remarkably fine and the whole makeup of the book is excellent.

Manual of Diseases of the Skin. With an Analysis of Twenty Thousand Consecutive Cases and a Formulary. By L. DUNCAN BULKLEY, A. M., M. D., Physician to the New York Skin and Cancer Hospital, etc. Fourth Edition, revised and enlarged. New York and London: G. P. Putnam's Sons, 1898. Pp. xi-362. [Price, \$1.25.]

IN this book a brief description of cutaneous diseases is contained. The first chapters deal with the anatomy and physiology of the skin, with the symptomatology, with nomenclature, with the relative frequency of skin diseases, etc. The use of the chapter on the relative frequency of these diseases is certainly not apparent; for how profits it a student to know that psoriasis occurs with a frequency of 3.5 per cent., etc., especially when that frequency is purely relative and individual to the observer? It may, for instance, be stated, as showing the value of such tables, that out of over two hundred thousand cases collected and classified by the American Dermatological Association for the years 1878 to 1893, only four hundred and nine cases of clavus occur. And yet, who has not a corn?

With chapter vii the description of the symptoms, diagnosis, and treatment of the various cutaneous eruptions begins, and in the succeeding pages the majority of them receive more or less attention according to their relative importance. The major symptoms pertaining to diagnosis are given briefly, and in a succinct manner. Etiology receives due attention, but pathological anatomy is not mentioned. As may be expected from the author's previous writings, an internal origin for the majority of skin diseases is emphasized, and in that regard his convictions are unmistakably apparent. The possibilities of microbial origin are allowed, but yet looked upon somewhat askance, the internal and systemic con-

ditions being of particular importance. Treatment receives much attention, and the suggestions in the text are supplemented by an elaborate formulary, from which may be culled every variety of remedy pertaining to the cure of skin diseases.

As a whole, the book may be said to be a personal one, representing the author's views especially, and giving a short but clear clinical picture of skin diseases, which will be of use to those who do not care to go more deeply into the subject.

Diagnosis by the Urine, or the Practical Examination of Urine, with Special Reference to Diagnosis. By ALLARD MEMMINGER, M. D., Professor of Chemistry, Urinology, and Hygiene in the Medical College of the State of South Carolina, etc. Second Edition, enlarged and revised. With Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. viii+9 to 124. [Price, \$1.]

THIS little volume furnishes the student with an excellent guide for his first studies in the relations between the changes in the urine and disease. No doubts or difficulties are allowed to appear in the text, and the mind is therefore not distracted by the necessity of remembering the numerous exceptions which unfortunately greet the young practitioner.

BOOKS, ETC., RECEIVED.

A Text-book on Practical Obstetrics. By Egbert H. Grandin, M. D., Gynecologist to the Columbus Hospital, etc. With the Collaboration of George W. Jarman, M. D., Instructor in Gynecology in the Medical Department of Columbia University, etc. Second Edition, revised and enlarged. Illustrated with sixty-four Full-page Photographic Plates and Eighty-six Illustrations in the Text. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1898. Pp. xiv+3 to 461. [Price, \$4.]

Diseases of the Ear, Nose, and Throat, and their Accessory Cavities. By Seth Scott Bishop, M. D., D. C. L., LL. D., Professor of Diseases of the Nose, Throat, and Ear in the Illinois Medical College, etc. Second Edition, thoroughly revised and enlarged. Illustrated with Ninety-four Colored Lithographs and Two Hundred and Sixteen Additional Illustrations. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1898. Pp. xiv+3 to 551. [Price, \$4.]

Transactions of the American Pediatric Society, Tenth Session, held in Cincinnati, June 1, 2, and 3, 1898. With an Index of Volumes I to X. Volume X.

The Bertillon Classification of Causes of Death Recommended for the Use of Registrars of Vital Statistics (after the First Revision of Paris, 1900) by the American Public Health Association and by the Conference of State and Provincial Boards of Health of North America. Issued under the Auspices of the American Public Health Association.

Pelvic Neuritis, or Inflammation of the Pelvic Nerve in Women. By William O. McDonald, M. D. [Reprinted from the *American Journal of Obstetrics and Diseases of Women and Children*.]

Il Nervosismo di questa fine di secolo. Per il Professore Leonardo Bianchi. [Estratto da *Elegia*.]

In causa d'impotenza. Pel Professore Leonardo Bianchi. Napoli: Gennaro Maria Priore, 1898.

La Truffatrice internazionale. Periza medico legale sulle condizioni mentali della signora Sibilla Priore.

Pel Leonardo Bianchi. [Estratto dalla *Rivista mensile di psichiatria forense, antropologia criminale e scienze affini*.]

Su le idee fisse lezione del Professore Leonardo Bianchi. [Estratto dalla *Clinica moderna*.]

Contributo alla diagnosi e alla cura della artralgie isteriche. Nota clinica pel Professore Leonardo Bianchi.

Miscellany.

The Hours of Drug Clerks.—"By a vote of 99 to 26," says the *Sun*, "the assembly has passed the bill restricting the hours of labor of the clerks of pharmacists and druggists in this town to twelve hours on Saturdays, six hours on Sundays, and ten hours on other days. In moving to recommit the bill, Mr. Henry asserted that it was opposed by nine tenths of the drug clerks, and that not a single drug clerk had appeared before the committee to favor the bill. The supporters of the measure lamely retorted that while the drug clerks had not appeared in person, they had been represented by 'labor organizations' to which they belonged.

"We venture to say that among the drug clerks of this town, a class of men as industrious and as ambitious as other men are, and, as a rule, intelligent beyond the average, there are very many who do object to and resent this attempt of the legislature to interfere with their business and diminish their wages. For if the bill becomes a law, and the law is enforced, their wages must be reduced as their hours of labor are diminished. If those hours are too long, they have the privilege of American citizens to seek other employment, but they do not need to be protected by the State or to have their day's work fixed by it as if they were children or feeble-minded. The fact that some of them put up prescriptions and sell medicines gives no ground for the interference of the State. The negligent labor of a steel-maker, an iron-molder, a mason, a carpenter, of any man in any occupation, may cause accident and death; nor can negligence and incompetency be suppressed by legislatures, even in the *Revised Statutes* themselves. The drug clerks should be left free to work so long as they choose, and their hours are no more a proper subject of legislation than those of bakers and candlestick makers.

"It would be highly convenient if nobody had to work, and no doubt the wisdom of legislatures will in time repeal the curse and forbid the sweat of the brow; meanwhile the drug clerks and the rest of us ought to be allowed to work according to our will, without being hampered by the philanthropy that meddles ignorantly with other people's business."

The American Public Health Association.—The chairman of the laboratory committee has issued the following preliminary notice: At the meeting of the American Public Health Association, September, 1898, it was decided to organize a standing committee of the association composed of those actively engaged in laboratory work in connection with health boards.

During the past few years the chief development in sanitary science has been in connection with laboratory work, especially bacteriological, so that every health board of importance now requires a special laboratory staff.

Thus, within a few years, the number of laboratory men actively engaged in hygienic work and research has increased a hundredfold. The necessity of some central organization which could further the development of sanitary laboratory work in both scientific and practical directions seems very obvious, and it would be of the utmost value to health boards if arrangements could be made by which their laboratory representatives could meet with those of other boards. It is hoped that as many as possible of the sanitary laboratories on this continent will be represented on the laboratory committee by some one who will be able to attend the meetings of the association.

The American Public Health Association has by its work in the past not only laid claim to be our central sanitary body as far as organization is concerned, but the work already done under its auspices in connection with the standardizing of methods of disinfection and methods of bacteriological investigation are fine examples of what may be accomplished by cooperative means.

The intention of the laboratory committee is not to overlap or interfere with the work of other committees, but as far as possible to help them in their work, and it is desirable that members of other committees engaged in laboratory work should be regarded as *ex-officio* members of the laboratory committee.

It has been found at the meetings of the association that there is a practical difficulty in introducing papers and discussions of a technical nature into the general proceedings, while, on the other hand, those matters which most interest laboratory men must be essentially of a technical nature. It has therefore been decided to hold sessions of the committee during the day or two preceding the general meeting or in spare time between the regular sessions.

A temporary organization has been effected, and the first general session of the committee will be held on October 30th, the day previous to the opening session of the general meeting in Minneapolis, in November, 1899.

Professor Welch, of Baltimore, has kindly consented to be honorary chairman. The work of arranging the programme has been undertaken by Dr. F. F. Westbrook, of Minneapolis, who in cooperation with Dr. Probst, general secretary, will decide which papers are of a technical nature, more suited to laboratory committee sessions than for general meetings.

Dr. A. Gehrman, of Chicago, has undertaken the editing of the proceedings and publication of the minutes of the meeting.

The line of work proposed is as follows:

1. Original short papers upon laboratory work and research. Summary reports of work accomplished during the year in the various laboratories.

2. Cooperative investigations, as on disinfection, water analysis, etc.

3. Short summaries of progress during the year in special lines of work.

Those engaged in laboratory work bearing upon hygiene are eligible as members, and those wishing to become members will kindly address the chairman, Dr. Wyatt Johnston, 74 Shuter Street, Montreal.

A Medical Bicyclist's Novel Defense. We learn from the London correspondent of the *American Practitioner and News* for March 15th that a doctor who was summoned at Portsmouth, England, for riding a bicycle on the footpath raised a novel defence. He stated that there was an act of Parliament which gave a doc-

tor permission to take the shortest cut when on his way to visit an urgent case. After an adjournment to allow him to produce the act, the magistrates decided in his favor.

The Late Dr. Timothy J. McGillicuddy.—At a regular meeting of the New York Celtic Medical Society the following resolutions were adopted:

The New York Celtic Medical Society has learned with profound sorrow of the death of our fellow member, Dr. Timothy J. McGillicuddy, who died of pneumonia on the seventeenth day of January, 1899, after a few days' illness and before many of his old friends realized that he was ill. The society has suffered a great loss in his death, and the profession a blow that it has keenly felt. He was one of the founders of this society, and we, its members who live to-day to enjoy its associations, feel greatly indebted to our deceased brother for bringing the organization to its present standing. The doctor was a constant attendant at our meetings and participated in the various discussions with a zeal peculiarly his own. He was a man of rare attainments, wise judgment, and honest purposes, "with charity to all and malice toward none." His writings and contributions to medical literature stand out to-day to his memory, and we, his associates, feel proud of him as a member.

Resolved, That in the death of Dr. McGillicuddy the Celtic Medical Society has lost one of its ablest and most valued members, and the science of medicine a scientific laborer and faithful investigator, and that the deep feeling of sympathy of this society be extended to his family in this hour of their deep sorrow, and that a copy of this memorial be forwarded to his family and also be published in the medical journals.

[Signed.] M. C. O'BRIEN, M. D.,
F. J. QUINLAN, M. D.,
G. D. MCGAURAN, M. D.

The New York Neurological Society.—Officers for the ensuing year were recently elected as follows: President, Dr. Frederick Peterson; vice-presidents, Dr. Joseph Collins and Dr. L. Stieglitz; recording secretary, Dr. Pearce Bailey; corresponding secretary, Dr. L. A. Conner; treasurer, Dr. Graeme M. Hammond; councillors, Dr. C. L. Dana, Dr. M. A. Starr, Dr. B. Sachs, Dr. E. B. Fisher, and Dr. J. Arthur Booth.

The Falsetto Voice.—At a meeting of the Orleans Parish Medical Society, of New Orleans, held on April 8th, Dr. de Roaldes presented a patient whom he had treated for falsetto voice. The man had previously appeared before the society and was now shown again in order that the change in his voice might be appreciated. The affliction dated from an attack of measles when the man was about fifteen years old. After an examination of the larynx, which was in a normal state, he was promised early relief if he placed himself entirely under Dr. de Roaldes's control and carried out a prescribed system of vocal exercise. After ten days' treatment the voice had changed from a high-pitched falsetto to a full barytone. Such voices, said the speaker, while resembling that of the eunuch, were entirely different. The trouble was easily relieved, while the eunuch's was due to lack of development and was incurable. The majority of persons with a falsetto voice breathed incorrectly; the abdominal muscles were contracted and respiration was shallow. The first step in the treatment was to correct this by deep and silent inspiration

followed by expiration. The vowels were then pronounced during expiration and the words gradually increased. The treatment lasted for an hour or two, and some did not require further direction. It was best to carefully guard them for a few days, however, as a return of the condition might occur. An attendant should be constantly with the patient and correct any change in the tone of voice for at least twenty-four hours.

Displacement of the Testicles.—At the same meeting Dr. Hamilton P. Jones related the case of a man who had recently consulted him, thinking he was a eunuch. During an encounter he had been struck on the scrotum, causing nausea and great pain. Next day he noticed that his testicles had disappeared from the scrotum and they had never reappeared. Examination revealed the absence of the testicles from the scrotum. The right testicle was found well up near the inguinal ring. At a corresponding point on the left side a fluctuant tumor was found, which was not painful when pressed upon. He was seventeen years old when the blow was received, and since that time sexual intercourse had not been attempted. Believing himself incapable of coition, he desired an operation for the replacement of the testicles. Dr. Jones declined to attempt any operation, thinking that the young man's extreme lack of confidence in himself was the most prominent cause of his condition.

Notice to Rectal Specialists.—At the time of the meeting of the American Medical Association in Columbus, on June 6th, 7th, 8th, and 9th, there will be a meeting of medical men engaged in the practice of proctology, for the purpose of organizing a society for the study of that specialty. Physicians interested in the project are requested to address Dr. William M. Beach, No. 515 Penn Avenue, Pittsburgh, Pennsylvania.

Dr. Achilles Rose.—We learn that Dr. Rose's book *Christian Greece and Living Greek* is to be translated into German and published in Leipzig; also that Dr. Rose has been asked to assist the editors of Roth's *Klinische Terminologie* in preparing the sixth edition of that work.

The Barnes Medical College, of St. Louis, held its commencement exercises on Wednesday evening, April 12th. The graduating class consisted of two hundred and three gentlemen.

The Sixtieth Anniversary of the Colored Home and Hospital is to be celebrated on Saturday afternoon, April 29th, at half-past three o'clock. The occasion will be of special interest in that the main feature is to be the dedication of the new buildings erected last year at One Hundred and Forty-first Street and the Southern Boulevard. These buildings include a distinct general hospital department with a modern operating room, a maternity pavilion, and a phthisis pavilion, in addition to a convalescent and home department. During the afternoon all these will be thrown open to the friends of the institution and to the medical profession.

Mr. Hamilton Mabie, Mr. Booker Washington, and the Hon. John W. Keller, president of the commissioners of charities, are to be the speakers of the occasion.

The Association of American Physicians. The fourteenth annual meeting will be held in Washington, on Tuesday, Wednesday, and Thursday, May 23d, 24th, and 25th. The programme contains the following titles: Idiopathic Dilatation of the Colon (Congenital), by Dr.

J. P. Crozer Griffith, of Philadelphia; The Relation of Idiopathic Dilatation of the Colon to Phantom Tumor, by Dr. R. H. Fitz, of Boston; A Case of Presystolic Mitral Murmur associated with Systolic Tricuspid Murmur and Jugular Pulse, by Dr. James Tyson, of Philadelphia; A Case of Mitral Stenosis with Fever (Non-malarial) of Relapsing Type, by Dr. F. P. Henry, of Philadelphia; The Immediate and Remote Effects of Athletics upon the Heart, by Dr. Alfred Stengel, of Philadelphia; On the Interpretation of Pulse Tracings, by Dr. A. R. Cushny, of Ann Arbor, Michigan; On the Operative Treatment of Spinal Tumors, by Dr. J. J. Putnam and Dr. J. Collins Warren, of Boston; On Tabes, by Dr. M. Allen Starr, of New York; On Kernig's Sign in Meningitis, by Dr. J. B. Herrick, of Chicago; On Astasia-abasia, with a Report of a Case, by Dr. J. C. Wilson, of Philadelphia; A Case of Family Periodical Paralysis, by Dr. J. K. Mitchell, of Philadelphia; The Continued Fever of Epidemic Influenza, by Dr. W. W. Johnston, of Washington; Relapse in Typhoid Fever, by Dr. William Osler, of Baltimore; Some Remarks on Typhoid Fever among the American Soldiers in the Recent War with Spain, by Dr. Victor C. Vaughan, of Ann Arbor, Michigan; Further Notes on a Case of Malta Fever, by Dr. J. H. Musser, of Philadelphia; Otitis Media in the Lobar Pneumonia of Children, by Dr. S. J. Meltzer, of New York; Endocarditis of Tonsillar Origin, with a Report of Five Cases, by Dr. F. A. Packard, of Philadelphia; A Case of Fatal Epistaxis, with a Study of the Blood, by Dr. George Dock, of Ann Arbor; On the Diplococcus Form of the Colon Bacillus, by Dr. J. G. Adami, Dr. Maud E. Abbott, and Dr. F. J. Nicholson, of Montreal; The Organism of a Case of Blastomycetic Dermatitis, by Dr. L. Hektoen, of Chicago; Tumors involving the Hypophysis, by Dr. James Stewart, of Montreal; Demonstration of an Acromegalic Skeleton, by Dr. W. P. Thayer, of Baltimore; The Application of Thyroid Extract in the Treatment of a Cerebral Neoplasm, by Dr. Starling Loving, of Columbus, Ohio; The Action of Hepatic, Renal, and other Cells upon Phenol and Indol, under Normal and Pathological Conditions, by Dr. C. A. Hexter, of New York; Experimental Research disproving the Theory that Paraxanthin Poisoning is a Cause of Migraine, by Dr. E. Pfaff and Dr. J. J. Putnam, of Boston; On the Toxicity of the Urine, by Dr. F. Foreheimer and Dr. R. W. Stewart, of Cincinnati; Perforation of the Stomach by a Foreign Body in an Infant Seven Weeks Old, by Dr. T. M. Rotch, of Boston; and An Experimental Study of Pancreatitis, by Dr. S. Flexner, of Baltimore.

The Greater Manhattan Obstetrical Society.—The secretary, Dr. M. Richter Bong, sends us the following report of a recent meeting, the president, Dr. M. Levator Ami, in the chair; other members in other chairs:

The paper of the evening was read by Dr. R. S. A. Brech, on "The Bacteriology of the Fetal Cord." The author announced that, after examining six thousand cords, he had found no bacteria. Sixteen thousand two hundred were examined and found four hundred and ten after birth, and the cords of short periods varying from one week to two months post partum. He concluded by saying that no previous case could ever be attributed to the cord, and he had now shown, in the only original investigation of its kind ever made, that no pathogenic germs existed in the cord at any time.

Dr. MESOBLAST JENKS, in opening the discussion, congratulated the reader on his remarkable paper. He, too, had made similar experiments many years ago and had reached the same conclusions. Might he ask Dr. Breech if he had used platinum needles in his researches?

Dr. BREECH replied that he had used aluminum needles, and a culture medium of agar-agar, gelatin-gelatin, bouillon-bouillon, beef tea, and salt, smeared with human blood and frog's serum. He had stated this in his paper in detail and was sorry that Dr. Jenks had not paid attention.

Dr. L. O. A. SMITH, of Omaha, was glad to be present and wished to congratulate the reader of the paper on his painstaking work, but he would refrain. He had had many cases of sepsis and had always attributed them to the cord and the germs clinging thereto. But, after elaborate researches done in his laboratory and published in the *North Greenland Medical Decade*, he had become convinced that the sepsis must be sought for elsewhere. He was surprised that Dr. Breech had not read his paper.

The PRESIDENT said his own researches in this direction had occupied twenty years and had recently been published in the *Medical Length*. Nevertheless, he agreed fully with the reader of the paper, but regretted to find that he was not familiar with the literature of the subject. He (the president) had used nutrient blood-vessels as culture media, and, although he had occasionally got a growth of bacteria, he attributed it to carelessness of techniques.

Dr. BREECH, in closing the discussion, was glad to see that the subject had aroused such interest, as it was a new one.

Dr. HYALINE C. DOE begged to make a preliminary report on his new treatment for eclampsia. Taking his cue from the name of the disease, he employed numerous clamps adapted in form and shape to every muscular apparatus of the body. When an eclamptic attack appeared, these clamps were applied and screwed on tight; and "where is the woman," asked Dr. Doe, "who can have a fit when every muscle is tightly clamped?" He had used these clamps in three cases and, although all the patients had died, he did not feel discouraged, for his statistics were as good as those of men who employed other treatment. An additional advantage of his apparatus lay in the fact that, after sterilization, it could be used about the house for other purposes.

Dr. BREECH thought this a very ingenious scheme, and would be glad to make use of it if he ever had a chance.

The PRESIDENT thought the measures extreme. He relied upon flushing of the kidneys and the suprarenal capsules. If necessary, he even exposed these organs and flushed them externally.

Dr. JENKS thought we were rapidly solving the question of eclampsia, and hoped to see the day when such seizures would be things of the past. He believed they were relics of barbarism and should be abolished.

Dr. FOSSA asked if any members ever used chloroform during an attack. He had read that chloroform was useful in eclampsia and had recently given a patient four ounces by the mouth and been surprised to see that her sufferings had only been increased. Only after her rather sudden death did she seem to regain her composure. In the next case, he would certainly use Dr. Doe's clamps, which were destined, he thought, to revolutionize obstetrics.

Professor MONTEREY BLENERHASSET LEAKING, the eminent teacher of Edinburgh, who was present, was invited to speak. Dr. Leaking said he was delighted with what he had heard and should return to his home to tell his colleagues of the marvelous American progress in obstetrics. Perhaps the society would be interested in his new method of treating posterior positions. Every obstetrician knew the annoyances and difficulties of these positions when they did not rotate to the front. Dr. Leaking had conceived the idea of version, not of the child, but of the mother. If, he argued, we turned the mother on her abdomen, what had formerly been a posterior position became of necessity an anterior one. The only difficulty he had experienced had been in preventing the child's head coming through the rectum. He would earnestly recommend this method to the society. He wondered that it had not been thought of before, considering its simplicity.

As Dr. Leaking took his seat the society broke into wild applause, and all the members took copious notes. Dr. Breech moved a vote of thanks to the distinguished visitor. Carried with one dissenting vote.

Dr. JAMES HYDROCEPHALUS EPIBLAST reported an interesting case, that of a primipara. Labor lasted nine hours, and the cord was wound once around the neck. The placenta was removed easily *à la Crédé*. The mother and child both recovered. He had neglected to observe the position. The interesting feature of the case lay in the fact that the father had not said: "I feel so much better now that it is over, doctor. I shall never forget you." (No discussion.)

Dr. R. ILIAC FOSSA reported a case of maternal impression in a primipara. The labor was normal in every respect, resulting in the birth of a fine healthy child. An hour after its birth the child was noticed to put its right index finger into its mouth. The mother was at once alarmed and remembered distinctly that twelve years previously she had once put her left index finger into her mouth while pondering deeply. Dr. Fossa called attention to the fact that, although the index fingers were different ones, the coincidence was most striking and confirmed his opinion, frequently expressed, that maternal impressions did undoubtedly impress.

The case recalled to the president one in his own very large and constantly increasing obstetric practice. The father of an otherwise healthy child occasionally drank as many as two glasses of beer a week while his wife was pregnant. At the child's birth it was noted that it bore a striking resemblance to a brewer who was an intimate friend of the family. The father, who drank this brewer's beer, and who was frequently away from home for several weeks at a time, had assured the president that only the close association of thought between himself and his wife could account for the remarkable coincidence. The president concluded with the sage remark: There are more things in heaven and earth than are dreamed of in our philosophy, Horatio.

The society voted that the legislature be informed that it desired the annihilation of midwives.

The meeting then adjourned for oyster soup with real oysters, thin sandwiches, water, and milk.

Koch's Lymph is now admitted into this country free of duty because it does not interfere with home consumption.—*Louisville Medical Monthly*.

The New York City Hospital.—Dr. Walter Benschel has been appointed pathologist to the hospital.

Original Communications.

WHEN TO OPERATE FOR APPENDICITIS.

NOTES ON TECHNIQS.*

By ROBERT T. MORRIS, M. D.

By "appendicitis" I mean infective, exudative appendicitis. This excludes such diseases as tuberculosis, cancer, or actinomycosis, which involve the structures of the appendix in their own specific kind of infection.

It excludes catarrhal inflammation of the mucosa of the appendix.

Tuberculosis, cancer, and actinomycosis of the appendix require operation because of their own specific nature.

Catarrhal inflammation of the mucosa of the appendix does not require operation, and it apparently does not cause symptoms which are referable to the appendix alone. It is an easy matter to make the differential diagnosis in most of these cases if one has given himself opportunities for learning.

Infective exudative appendicitis requires operation, as a rule, as soon as the diagnosis of appendicitis has been made. That is a rule that I proposed early in the present decade, and it aroused widespread adverse comments for two chief reasons: First, because some readers were not quite familiar with the meaning of the word "rule." Secondly, because some readers assumed that it was intended to cover cases that were not accurately diagnosed.

Appendicitis, according to my definition,† is an infective, exudative inflammation of the appendix vermiformis cæci, originating in any local cause for the production of an infection atrium in the tissues of the appendix, and progressing by bacterial invasion into the tissues of the appendix. The chief cause for bacterial infection from the lumen of the appendix is the formation of an infection atrium in the mucosa of the appendix. Such an infection atrium may be produced in various ways. Commonly, by twisting of the appendix by the action of the right psoas muscle; by ulcerative erosion at the site of a concretion; by ulcerative erosion due to the action of entozoa; by desquamative erosion following catarrhal inflammation of the mucosa of the appendix.

Having begun as a definite lesion, appendicitis progresses to various degrees of tissue destruction, according to the virulence of the species of bacteria that have entered the infection atrium, according to the relative value of the resistance factors of the patient, and according to the anatomy of any given appendix. The principal bacterial malefactors are the colon bacilli

and pyogenic streptococci. The principal resistance factor is leucocytosis. The principal anatomical defect is a narrow tube of muscularis and peritonæum which causes compression anæmia of infiltrated lymphoid structures.

The relative importance of these factors in any given case is always unknown, and, being unknown, the physician can only speculate as to their behavior in any case of appendicitis.

The character of their behavior is determined only by operation or by final inflammatory results. Such being the case, we are to operate as soon as the diagnosis of appendicitis has been made, in cases in which neighboring structures are exempt from infection at the time when the patient is first examined, in order to prevent infection from extending into those structures.

We are to operate as soon as the diagnosis of appendicitis has been made in cases in which widespread infection is found on first examination, in order to prevent such infection from extending still further.

We are to operate as soon as the diagnosis of appendicitis has been made in cases in which infection is subsiding when the patient is first examined, in order to avoid the surprises of sudden exacerbation, to avoid tedious convalescence, and post-infective peritoneal adhesions of troublesome character.

We are to operate as soon as the diagnosis of appendicitis has been made in cases in which all evidences of acute infection have subsided when the patient is first examined, provided that on accurate palpation we are able to determine that the appendix is the seat of chronic infection. The reason for this is because after one or more acute attacks of appendicitis have subsided we find hard concretions or entrapped fecal contents in nearly twenty per cent. of the cases. We find partial or complete mucous inclusions in more than eighty per cent. of the cases.

Some surgeons argue that early operation is desirable on the score of avoiding post-operative ventral hernias; but I do not believe in the danger of post-operative hernias after operation at any stage of infection, provided that the structures of the incised wound are properly sutured. If post-operative hernia does occur in improperly sutured wounds, such hernias offer opportunity for very pretty and successful secondary operation, provided that at the secondary operation the muscular planes are dissected apart separately and separately sutured.

The reason why we are to operate as soon as the diagnosis of appendicitis has been made is that the surgical death rate is lower than the medical death rate, if the surgical work is properly done. Another reason is because the suffering rate under proper surgical treatment is less than the suffering rate under medical treatment.*

Another reason is because the loss of time rate for the

* Read before the Society of Alumni of Bellevue Hospital, March 1, 1899.

† See *Lectures on Appendicitis*, third edition.

* See testimony of patients. *Lectures on Appendicitis*, third edition.

patient under proper surgical treatment is less than the loss-of-time rate under medical treatment.

In connection with this presentation of the subject of appendicitis I wish to make a brief report upon the results of certain kinds of operative technics in a class of cases that are commonly thought to be of the most fatal type. It is now a well-known fact that the operative death-rate in appendicitis is less than one per cent. at the hands of several surgeons in cases in which infection is practically limited to the tissues of the appendix at the time of operation, no matter whether these are primary infection cases or post-inflammatory cases with extensive adhesions. It is not commonly understood that the death-rate may be made small in the class of cases in which infection is widespread at the time of operation. The list of cases here presented consists of seventy-six consecutive cases of the class in which infection had gone on to abscess formation or to liquefaction of plastic lymph. I do not know how else to describe the type of infection in which bacteria are causing such an infection of the peritonæum that plastic lymph fails to coagulate or is liquefied after coagulation.

The list includes cases of the most desperate kinds of infection that are seen by the surgeon who is engaged in abdominal work. And yet in the whole series there were but eight deaths, and there is but one post-operative ventral hernia, so far as I am aware. My means for being informed consist in a request to patients and their physicians to report upon all post-operative complications, and all of these patients were of the private-patient class, and under the charge of physicians. Not all patients report, but I believe that hardly any hernias follow the method of accurate closure of the abdominal wall, leaving only a small wick-drain opening in cases where drainage is really necessary.

In these seventy-six cases the patients were operated upon after I had dropped out of my operative technics certain methods which I believe to have a special death-rate of their own, and which are in common employment to-day.

Before I had learned to discard the methods that are in common use, my death-rate in the class of appendicitis cases with widespread infection was discouraging.

Resources which I believe have a special death-rate of their own are here enumerated in the order of their injuriousness. First comes iodoform-gauze packing. This is harmful in two ways. The peritonæum absorbs iodoform with such rapidity that toxic effects are produced in some patients from very small quantities. If we examine the urine of patients who are thought to be dying from septicaemia or exhaustion, and who have iodoform gauze in the peritoneal cavity, the result will surprise those of us who have not made such examinations. A little urine stirred up with a pinch of calomel in a saucer will show the brownish reaction, as iodide of mercury is formed in cases in which the urine contains free iodine. A peculiarity in these cases of death from

iodoform poisoning is the good appearance of the wound.

Gauze packing alone is probably next to iodoform-gauze packing in order of injurious resources which have a special death-rate of their own. Strong and well men can not bear in the abdominal cavity the presence of a yard of gauze, and I do not know why a weak and exhausted patient should be asked to bear what can not be borne by a strong man. Aside from the shock caused by gauze packing, the gauze causes excessive lymph exudation, and this lymph then forms a large culture medium for bacteria, or it forms strong, troublesome adhesions of viscera. Further, when gauze packing is removed it causes so much distress that surgeons sometimes anæsthetize the patient when the dressing is made. Gauze packing often causes post-operative obstruction and ileus by its mechanical effect. It is almost as harmful in this respect as strips of gauze carried to various points among viscera for drainage, but the gauze strips have one special death-rate of their own when peristalsis causes them to encircle loops of bowel.

Lastly, it is impossible to guard well against the development of post-operative ventral hernia in any case in which gauze packing or multiple gauze strips have been employed. Gauze packing and gauze strips are not only harmful but they are unnecessary, and they can be replaced by a small narrow drainage wick covered with gutta-percha tissue to avoid adhesion formation. The narrow wick allows the wound to be closely and accurately sutured. It must be managed with a knowledge of the mechanical principles involved in dealing with capillarity.

A method which must have a special death-rate of its own consists in leaving infected appendices among adhesions. Such appendices are frequently gangrenous in part and they often contain concretions. The necessity for leaving such appendices among adhesions disappears almost completely after one is sufficiently trained in adhesion work.

The plan of making long incisions and of partial evisceration of the patient under the imagined necessity for cleansing pus and lymph from loops of bowel is a dreadful method, and one which is not based upon our knowledge of the fact that leucocytosis and lymphatic circulation will do the work much better than the surgeon can do it, provided that the surgeon possesses modern knowledge of the subject of leucocytosis and of peritoneal lymphatics. I object to having evisceration methods presented to surgeons who are so bold as to think well of the proposition. If we remove the chief pus collections rapidly with hydrogen dioxide, followed by saline solution, and if we carefully avoid handling or even seeing loops of bowel, we are doing what is best, if my statistics are of any account in the way of testimony. In these cases of advanced septic infection of the peritonæum, I believe it to be the duty of the surgeon to get in quickly, to get out quickly, and to be gentle. It

is wonderful to see how well badly infected patients respond to treatment of the gentler sort, and how quickly they take the favorable turn if we do not hold them down with gauze, with iodoform, or with morphine.

A method which may not have a death-rate of its own, but which certainly causes delay in operative work, consists in carefully walling off an abscess cavity with gauze arranged to protect the peritoneum. This requires a rather large incision, and it requires the expenditure of time. It is based upon conventional ideas of cleanliness rather than upon a knowledge of leucocytosis. I find it much better to work rapidly in separating adhesions, and to allow pus to flow as fast and as freely as it will anywhere over the peritoneum, allowing it to follow the lines of least resistance, and blowing it out with hydrogen dioxide from time to time as the work proceeds.

During the time covered by the seventy-six cases in the subjoined report, I operated in every acute case of appendicitis that I saw, with the exception of those of one patient who had a dilated heart with advanced cardiac complications, and two patients who died just before I got to them. In patients who were nearly moribund at the time of operation a strychnine pulse was obtained before operation was begun, and codeine was administered hypodermically to lessen the disturbance caused by anæsthetics. During the time covered by the cases in this report I operated in a much larger number of cases in which the appendix was perforated, or gangrenous in part, but infection had not gone on to the point of abscess formation or to liquefaction of lymph. There were no deaths at all in this class of cases.

My seventy-six cases of the most dangerous class are grouped according to a kind of loose classification.

General Suppurative Peritonitis.—Three cases. Three appendices removed. Two patients recovered. The one who died had a fluttering pulse of about 160 and gasping respiration when I operated. He improved after operation for a few hours and died in one of several "sinking spells." One who recovered has a ventral hernia, the only hernia in the list, so far as I am aware. The other patient who recovered has a fecal fistula due to sloughing of patches of colon. This is the only unclosed fecal fistula in the list.

Septic Peritonitis of Various Degrees with Liquefied Lymph in Place of Abscess Formation.—Fifteen cases. Fourteen appendices removed. Fourteen patients recovered. The patient who died was lost through post-operative intestinal obstruction. He was far from New York, and I could not apply resources which have been successful in relieving post-operative intestinal obstruction in cases under the care of my assistants and nurse.

Multiple Acute Abscesses.—Fourteen cases. Twelve appendices removed. Four patients died. One who died had the entire peritoneal cavity apparently filled with small encapsulated abscesses. I opened eight or ten and saw that the patient was dying while I was at work

He died two hours later. Another who died had a large pelvic abscess, which I overlooked because it was in the pelvis and distant from the abscess which was opened.

Another who died seemed to die actually from exhaustion. I do not like the word "exhaustion," because it is usually employed when one feels cowardly about facing the word "septicæmia." In this case the patient had managed enormous business complications for more than a day after the development of a large abdominal abscess, and with a rapid, feeble pulse. After the operation there was no extension of infection, apparently, but Nature made no attempt at repair. The patient simply failed from inanition. He seemed to have exhausted all his reserve strength before the operation.

The fourth patient who died was lost from post-operative intestinal obstruction. This patient was also far from the city and out of reach of the resources that would have been applied in a hospital.

Single Acute Abscesses.—Thirty-three cases. Thirty appendices removed. Thirty-one patients recovered. One who died was lost because the abscess opened into the ureter before operation, and he died from suppurative nephritis. The other patient who died was a feeble child who had carried a large abdominal abscess for several days, and who was so exhausted at the time of operation that he could not carry on repair.

Old Abscesses.—Twelve cases in which acute symptoms had subsided and the patients were walking about, some of them with large multiple abscesses. Twelve appendices removed. All the patients recovered.

THE TECHNIQUE OF THE BOTTINI OPERATION.

By RAMON GUITÉRAS, M.D.

ONE of the most important operations that has come into the field of surgery during the last few years is the procedure for reducing the impediment in cases of hypertrophy of the prostate gland, and thus allowing the bladder to once more empty itself.

This operation was devised by Bottini, of Pavia, in 1872, but did not receive much favor until about a year ago, when it was taken up by Freudenberg, of Berlin, who modified the instrument used in performing it until it has reached its present state of perfection.

The instant that the benefit derived by this means was made generally known, it created a *furore* among the genito-urinary surgeons, which has never been equaled by any operation in the past.

Notwithstanding the fact that most elaborate articles have been written upon the subject by Freudenberg, Meyer, Viertel, Lohmstein, Morton, Hure, Lewis, and others, it does not seem as yet to be fairly understood by the majority of practitioners as it should be, when we consider that it is an operation which any one can per-

form who is familiar with the anatomy of the genitourinary organs in health and disease.

It is therefore my object to try to describe in detail how this important operation should be performed, in order that any of my readers who find it necessary may be able to make use of it without fear of making any serious blunder. I shall also endeavor to describe briefly what the degree of prostatic hypertrophy is which would lead us to perform it, and what steps should be taken in after-treatment in ordinary cases and when complications occur.

Let us then consider what the prostate gland is in health, and later how it is affected by age and disease.

The prostate gland is an organ shaped like a truncated cone, flattened in front and behind, or, in other words, shaped like a horse-chestnut, which surrounds the neck of the bladder and the beginning of the urethra. Its base is the part in contact with the former, and its apex that which is contiguous with the latter. It is about an inch and a half wide, an inch and a quarter deep, and three quarters of an inch in thickness. It is composed of three lobes: two lateral ones which meet in front and behind, and a middle one situated between them posteriorly under the floor of the urethra, which does not manifest itself until the patient is pretty well advanced in years. This third or middle portion is not strictly speaking a lobe, but consists of hypertrophied tissue situated in the space behind the upper end of the urethra and the neck of the bladder, where the two lateral lobes diverge, which presses up the urethra at its vesical orifice, thus rendering it impossible to empty the viscus completely.

In structure the prostate gland is made up principally of muscular and glandular tissue, the glands resembling racemose glands. They occur in lobules, forty or fifty in number, and their ducts open into the floor of the urethra in twenty or more places. The muscular fibres are found along and around the urethra, and radiate from it. They are mixed with fibrous and elastic tissue and support the glandular elements forming the stroma. The gland is incased in its capsula propria, which can be separated from it only with great difficulty. External to this is a second capsule, which is continuous with the deep perineal fascia at its apex. Between these two capsules is the prostatic plexus.

The prostate is situated between the rectum and the symphysis pubis, lying immediately in front of the former and about three quarters of an inch behind and below the latter. It is also an inch and a half from the anus.

The function of the prostate is to secrete a milky fluid containing molecular matter, squamous and columnar epithelium, and granular nuclei.

The usual way of examining a prostate is by the rectum, the gland being found an inch and a half from the anus anteriorly, where its size, consistence, and outline can be noted.

Hypertrophy of this gland rarely occurs before the forty-fifth year, and generally after the fiftieth, although troublesome hypertrophy is not found in more than eight or nine per cent. of old men. In these enlargements the fibrous and muscular elements seem to take more part than the glandular, and tend to arrange themselves into distinct nodules of a spherical form. These growths tend to protrude where the resistance is least—that is, on the urethral aspect. They are found to bulge, especially in the floor and sides of the urethrovessical orifice, forming the so-called enlarged middle lobe. They may reach the size of an orange and even larger.

As the prostate hypertrophies, the orifice of the urethra becomes elevated, and the return flow of blood from the vesical veins is impeded by pressure upon the prostatic plexus. This results in imperfect evacuation of the bladder, and consequently in residual urine. Cystitis develops, as is evidenced by a frequent desire to urinate (due to irritation of the neck of the bladder from venous congestion) and the other symptoms usually present.

If the hypertrophy continues, these symptoms increase or are replaced by graver ones, and we have dilatation of the bladder, hypertrophy of the muscular and fibrous coats, and the formation of diverticula; dilatation of the ureters and pelvis of the kidney, congestion and catarrhal inflammation of the entire urinary tract, with an accumulation of the urinary and inflammatory products, and perhaps septic inflammation extending from the bladder to the kidney (pyelonephritis), resulting in chronic uræmia and death.

Thus we see what conditions must be relieved in order to benefit our patient. His general health should be improved; his bowels regulated, and his skin kept active by warm baths; his clothing should be warm, to prevent taking cold, and he should eat moderately and drink plenty of water. His urine should be kept in the best possible condition by the use of internal urinary antiseptics, as the benzoates, the salicylates, boric acid, etc. *Ol. gaultheriæ*, *eucalyptus*, and *urotropin* are also of great service. Locally, his bladder should be emptied by catheter twice a day and washed out with a boric-acid solution, other antiseptic solutions, as permanganate of potassium, nitrate of silver, and borolyptol, being used at intervals.

When the patient has been brought into the best possible condition generally and locally, an operative procedure can be considered. Ligation of the internal iliacs, resection of the vas deferens, castration, prosta-tectomy, and the formation of a perineal fistula have all had their day and advocates, and the mass of practitioners seem now to be coming to the opinion that the operation by the Bottini galvano-caustic incisor is the quickest, the simplest, and the best.

The change in the size of the prostate is noted by rectal and urethral examination.

When a patient over fifty years of age presents himself, suffering from the symptoms already described, it is natural to suspect prostatic trouble, and after he has voided his urine we examine him with a catheter to see if he has any residual urine or any prostatic impediment. The catheter first used should be straight, of soft rubber, and velvet-eyed, about the size that will easily glide through the canal.

This should be passed in slowly and gently. If at six and a half or seven inches from the meatus it comes against a barrier, it will probably be found to be the hypertrophied middle lobe, and the urethral floor will be found to be raised at this point. An elbowed catheter (Mercier) of the same size and material should then be tried, and, if this will not pass, smaller ones should be used until one has been made to ride over the prostatic hillock into the bladder. The sensation of riding over this elevation is well known to one familiar with the feeling of the prostatic urethra in cases of hypertrophy. A straight catheter of the same size as the *coudé* can not usually be made to pass. The amount of residual urine in the bladder and its condition should then be noted, and the distance (measuring from its eye) to which the catheter has to be passed, in order to draw urine, should also be observed, as it shows the length of the urethra in the case. Ordinarily, eight inches of an instrument, reckoning from the eye, is sufficient, and if it is necessary to introduce one further, the extra distance to which it has to be passed will indicate the increased length of the urethra—that is, of its prostatic portion. This gives us some idea of the length of the prostate and the extent of the hypertrophy in its long diameter.

The rectal examination shows the increase in size in most cases, although there is no rule regarding this. We often observe prostates that seem to be as large as an orange by rectal feel in cases where there is very little urethral obstruction noticed by the catheter, and in which there is very little residual urine present; while, on the other hand, we may notice by rectal examination a small, hard prostate which does not seem to be as large as normal, and yet, when an instrument is passed by the urethra, a marked impediment is noticed, and a large amount of residual urine is found to be present. Such a condition is accounted for by the middle lobe growing up into the urethra, and not down and backward, so as to be easily noticed as a protrusion in the rectum. In a prostate that feels large on rectal palpation the lateral lobes are usually the part principally involved.

In examining the prostate by the rectum, the forefinger of the physician is the one generally employed, and the length of the digit as compared with the prostatic landmarks in health and disease should be taken into consideration.

The part of the rectum explored in our prostatic investigations is the anterior wall from the anus to the base of the prostate. This surface lies at an angle, more

or less obtuse, with the apex of the prostate corresponding to that of the angle; for the first part of the rectum extends upward and forward from the anus to the apex of the prostate, while from this point the direction is rather upward and backward. The forefinger from tip to base—that is, to the web—is from three inches to three inches and a half in length; the first part of the rectum is an inch and a half long, and the prostate is an inch and a quarter, which would make a distance of two inches and three quarters from the anus to the base of the gland, if one were to follow the angle that I have spoken of; but, of course, going in a straight line to the base shortens this somewhat. If the distance to the base of the gland were not shortened in this way, the man with a forefinger three inches in length would not be able to feel the base of the prostate in a case with over a quarter of an inch of hypertrophy, and he would not be able to explore the region of the bladder trigone or seminal vesicles at all. This is not the case, however, and some of the surgeons with short fingers are most skillful diagnosticians. In my own case, I have a forefinger three inches and a half long, and I have never seen a case of prostatic hypertrophy where I could not feel over the edge of its base per rectum. I have frequently, however, examined cases of enlargement of the gland where my colleagues present at the time could not feel over its base.

Some authors hold that there are a number of different forms of prostatic hypertrophy, but that the principal ones are the glandular and fibromuscular. They claim that in the former the hypertrophy consists principally of glandular elements, in which case we have the large succulent prostate, and that in the latter the muscular and fibrous tissues are principally involved, in which case the enlargement is not so marked, but the tumor is exceptionally hard and resisting. These observers also hold that the first group is suitable for enucleation, while the second is better for the Bottini operation.

In answer to this I would say that I have performed the Bottini operation on one of the first variety as large as an orange, in which case permission for an operation by enucleation could not be obtained, and I have failed to enucleate one of the typical, indurated, connective-tissue hyperplasias (the fibromuscular). I am watching the former case with much interest. His prostate was two inches long from base to apex, and I made the maximum incision in it posteriorly—that is, one-fourth of a centimetre long.

As we have now completed the review of the prostate in health and hypertrophy, let us take up the important part—namely, that of the operation, and describe somewhat at length the instrument, the apparatus connected with it, and the way it should be used.

The incisor is an instrument whose scabbles closely a Thompson lithotrite in its shape and formation, the great difference being that the incisor blade of the litho-

trite is replaced by a thin, dull blade, which is connected with a battery and acts as a cautery knife. It is worked by a wheel attached to a screw in the handle, as is a lithotrite, while the outside shaft, or female blade, is kept cool by a stream of water constantly passing through it. The difference in the working of the two instruments is that the lithotrite is first opened, and, after grasping the stone, is closed, the male blade being pushed forward toward the female, while in the incisor the beak is caught behind the prostate while closed and then opened, the male blade being drawn backward away from the female. My object in this preface is to compare the instrument under consideration with one that has been for a long time familiar to the eye of the physician, in order that he may have a better idea of its general appearance. In describing it individually, I will say that the incisor, taken as a whole, is an instrument sixteen inches and a half long, and consists of a shank shaped like a sound, eleven inches long; a rounded cylindrical handle on the proximal end, three inches long; and beyond this a straight pivot for the attachment of the electrical cable contact; a wheel working the Archimedeian screw in the handle of the instrument, which draws back the cauterizing blade and the centimetre scale on its proximal side. From the tip of the instrument up into the handle on its upper or concave surface is a slot, through or along which the female cautery blade passes.

FIG. 1

The instrument is made up of two distinct pieces, one fitting into the other—that is, a shaft within a shaft. The outside piece, from the beginning of the handle *Gr* to the end of the instrument, is the female blade. It is a sleeve with a slot running through it composed of the soundlike shank *F* and the expanded handle *Gr*. The handle has around it on the inside a thread into which the screw thread of the male part fits. The remainder of this female part is hollow, so that water may run through it, and there are two nozzles, *K*, extending down obliquely from the handle on either side, which serve as water pipes to which the tubing is attached, one leading up to a reservoir on the wall, the other down to a receiver on the floor. The water from the reservoir

flows down the first piece of tubing through the instrument and then down through the other piece into the pail or receiver on the floor. This is called the cooling apparatus, applying especially to the hollow part of the instrument with its connections. The inside piece from the pivot *C* to the end *Pl* is the male blade. This latter, consisting of a shaft with its blade *Pl*, screw thread, centimetre scale *Sc*, and pivot *C*, can be entirely withdrawn from the female shaft, washed, cleaned, disinfected, and put back again. The screw that slides the male blade backward and forward in the female slot is entirely hidden from sight in the handle, as is the centimetre scale, when the instrument is closed—that is, when the shaft of the male blade is hidden from sight in the female.

The cable contact *P* is a cylinder into which the electrical cable *L* is inserted, the other end of which fits over the pivot *C* of the instrument.

The next important consideration is the battery. This is exceedingly bulky, and, although called light, weighs over eighty pounds. It is about eighteen inches high and ten inches wide. When the battery is closed, two dials can be seen on the front of the box, one semilunar in shape, with three fingers upon it and an indicator; the other, below, round, with fifty figures upon it, each representing an ampère, and a revolving hand to point out the number indicating the strength of the current used.

FIG. 2.

The upper segment of the front of the box (battery) can be lifted up, disclosing the screws and switches for turning on the current.

The two binding posts marked "use" on the left are connected with the two cable terminals; the two posts on the right are to connect with the attachment cords from the mains for charging the battery. Between the two sets of posts is a black screw with an arrow beside it to show which way it should be turned in order to

turn on the current. On the upper and back part is a switch with a tongue pointing down to 0 (zero), meaning that neither of the two cells of the battery is connected. By moving the tongue to the left (No. 1) one cell, and by moving it to the right (No. 2) two cells are turned on.

Directions for Using the Battery.—"Connect the two cable terminals with the two binding posts on the left-hand side marked 'use.' Throw in two cells by turning the tongue of the switch to No. 2. Turn on the current by twisting the black screw situated between the four binding posts to the right, when the needle of the ampèremeter will soon show the strength of the current. For the operation a current is needed sufficient to heat the cautery knife to a red glow, generally from forty to forty-five ampères."

Note.—Precaution should be taken to have the male terminal of the instrument entirely introduced into the female terminal of the cable.

FIG. 3.

Rule for Charging the Battery.—"To charge this battery, connect it with the current from some main, using a strength of seven ampères and a half for eight hours. It is advisable to send it to some electric-light plant for this purpose. If the current is indirect, this is done by means of a transformer; but if direct, a motor is used in addition to the transformer.

If the operation is done in an institution where there are electric lights, it is much better to make use of the street current, as then it is not necessary to carry about the heavy battery, and one is sure of sufficient electricity for any number of operations.

If the current is indirect, it is simply necessary to make use of a transformer to reduce the 104-volt current of the street to four volts.

If the current is direct, a motor must be used in addition to the transformer to reduce the current to the strength desired.

"In using the transformer, the current from the street mains is led into the primary coil by connecting the attachment cords from the two binding posts on the

right of the instrument (transformer), after first threading the ends of the cords through the diagonal holes in the wood base at that end. The secondary coil is wound on the movable spool. It is operated by a

FIG. 4.

ratchet device, and the terminals are brought out of two pin or locket attachments mounted on one head of the coil to which the cautery cord can be attached. By moving the coil to the right the current is increased, and vice versa.

"The apparatus is fitted with a switch at the back which automatically cuts off the current from the mains when the cover is closed. The connection of the transformer with the ampèremeter and incisor is accomplished as follows: Connect one end of a short cable of about one yard in length with the one socket on the movable spool of the transformer, the other end with the binding post A of the ampèremeter. One terminal of the heavy cable furnished with the incisor is then connected with the binding post B of the ampèremeter, while the other terminal of the incisor cable is connected with the free socket on the transformer spool.

"In this way the current travels from the mains into the transformer, thence through the ampèremeter into the incisor, and then back into the transformer, thus closing the circuit.

"Should there be a sudden interruption of the current, look to the porcelain plug, which is easily taken apart, as a safety fuse of lead wire may be burned out, which is easily replaced by the surplus fuse wire furnished with each transformer.

"The transformer and the portable ampèremeter are very light and can be carried about with ease. The dial of the ampèremeter shows the number of ampères being used, the same as the dial on the face of the battery."

The anatomy of the parts in health and the particular disease, together with the instrument and apparatus,

FIG. 5.

having been thoroughly explained, it only remains to be shown how one works upon the other at the time of the operation. The entire apparatus should be arranged and tested before the operation, in order that everything may run smoothly when once it has begun.

The reservoir containing the cold water should be hung on the wall on the side corresponding to the patient's left. The tubing coming from this should be attached to the water pipe on one side of the handle of the instrument, and another piece of tubing should be attached to the other pipe, and from there extend to some vessel on the floor. The instrument should then be held over the middle of the table in the position corresponding to the one in which the patient is about to be placed, and water should be allowed to run through it to see if it makes the circuit from the reservoir to the receptacle through the tubing and instrument without being impeded in its course. The battery is then placed upon a high stool or table on the left of the patient in a position where the dial can be seen and where the screw for turning on the current can be easily reached, if necessary, during the operation by the operator from his position at the foot of the table. The cable should be attached to the posts of the battery, and the pivot on the end of the handle of the instrument. The tongue of the switch on the back of the battery should be turned to Fig. 2, thus throwing in two cells. Connection should be made by turning the contact screw on the cable contact. The black screw on the top of the battery should be twisted to the right, thus turning on the current until the blade of the instrument has been turned to a cherry red, when the number of ampères indicated by the hand of the ampèremeter should be noted. The instrument can then be said to be ready, and the current having been turned off and the cells thrown out again, it should be placed beside the battery, when it will only remain to put the patient in readiness for the operation.

The relation of this preparatory drill may seem to be unnecessary to the reader, but he will find out, if he sees many operations performed, that it is of vital importance.

The patient is placed upon the table at full length on his back, and the final preparations for the operation are entered into—that is, the washing out of the bladder and the anæsthetizing of the part.

A *coudé* (elbowed) soft-rubber catheter lubricated with glycerin, having been passed into the bladder, the urine is drawn off, and the bladder washed out with a boric-acid solution by means of a large Uitzman or Guyon hand-syringe, until it comes away clear. When the bladder is clean and empty, an ordinary urethral hand syringe is filled with a four per cent. solution of eucaïne, which is injected through the same catheter, and, while it is being thrown in, the catheter should be slowly withdrawn, thus allowing the solution to come in contact with all parts of the neck of the bladder and

the deep urethra. A syringe of the solution should also be thrown into the anterior urethra and held there for a few seconds.

From this moment the work should be done quickly and accurately, and I have observed that the quicker the operation is performed after this injection of the anæsthetic the less painful it is to the patient.

If cystoscopy is now performed, the time required for it will usually be sufficient to allow the effect of the anæsthetic to wear off before the actual operation is performed, and for this reason I think it advisable either to use the cystoscope at an earlier date or to again inject an anæsthetic after cystoscopy. Again, cystoscopy is often more painful than the operation itself. It seems to me for this reason that it is advisable to omit the question of cystoscopy at this stage and consider it as having been performed previously when the patient was examined.

Therefore, after the eucaïne solution has been injected into a clear and empty urethra and bladder, the catheter should be quickly introduced again and six ounces of boric-acid solution injected into it by the large syringe.

The catheter should then be withdrawn and the incisor inserted. This often catches in the prostatic urethra. In this case the handle of the instrument should be pressed down so that the end may be pushed up over the prostate and through the upper part of the vesical orifice. If it does not enter immediately, a sand bag or pillow should be placed under the patient's hips, after which the instrument can usually be pushed in without further difficulty. If it can not, however, there are only two things to be done: one is to anæsthetize the patient and thus relieve the spasmodic contraction of the neck of the bladder, and the other is to give up the operation. If an anæsthetic has to be given, I prefer laughing gas, as the patient is quickly put under its influence and comes out from under it almost immediately after the operation is finished. In four cases I have not been able to enter the bladder, and yet I have felt the beak of the instrument in the prostatic urethra through the rectum. In three of these cases I was obliged to desist after trying for about ten minutes in each one to make it enter. In each one of these cases I afterward went in almost immediately when the patient was under the influence of the gas. In the fourth case I was obliged to desist on account of not having an anæsthetic, and afterward did not have another opportunity of performing the operation. With the patient under the influence of nitrous-oxide gas there is practically no danger of death from anæsthesia, and the patient is perfectly quiet and does not tend to pull away, as he often does when not anæsthetized. The small cylinder put up in a portable case by the White Dental Company is light, inexpensive, and contains about enough gas for three operations, thus well accompanying the Kny-Scheerer battery, which in its turn contains just about enough electricity for three operations.

After the instrument is in the bladder, the forefinger of the left hand should be inserted into the rectum and its tip hooked over the base of the prostate in the median line. The handle of the instrument in the other hand

FIG. 6.—The instrument in position for cutting as indicated by the finger in the rectum.

should then be turned until the beak is looking downward, when it should be drawn forward until it catches behind the prostate. Here it can usually be felt by the tip of the forefinger in the rectum, which is hooked over the base of the gland, as in Fig. 6.

It does not seem to me, however, that the margin of the base of the prostate, as felt per rectum, is a sure guide to its edge in the bladder, as I think that the middle lobe frequently extends back farther in the bladder than it does in the rectum. I therefore am of the opinion that it is only necessary to hook it behind the middle lobe in the bladder, and to make the end of the instrument exactly correspond to the end of the rectal finger pressing up the margin of the base of the prostate.

At this point of the introduction of the finger in the rectum it is often necessary to draw up the thighs until they form an obtuse angle with the body as, when they are extended, there is a tendency to press them together, which seriously interferes with the rectal touch. In one of my first operations I was so anxious to have the point of the instrument in the bladder exactly correspond to the rectal margin of the base of the gland that in pulling it forward until they touched I was conscious that the end of my instrument was riding over something before it was exactly over the end of my finger. The result of this operation was that, although the pa-

tient could pass more urine than before, he still had considerable impediment. I think that in this case the prostate extended farther back in the bladder than in the rectum, and that the sensation of riding over something with the end of the instrument that I experienced really consisted in drawing it forward over the vesical edge of the base of the gland, and thus making my cautery incision from a point in front of the beginning of the obstruction, which, of course, left a dam behind it over which much of the urine could not pass. It would therefore seem that the rectal finger is more useful as an approximate than as an absolute guide.

To go back again to the point where the beak of the instrument was caught behind the middle lobe of the prostate. At this stage the finger of the left hand is withdrawn from the rectum, and the same hand grasps the handle of the instrument with the knuckles up. The elbow of the left arm rests upon the table between the legs of the patient, and the fingers of the right hand grasp the wheel of the Archimedeian screw at the end of the instrument, as in Fig. 7.

Note.—The handle of the instrument in this figure should be raised higher, so that the beak will sink down behind the prostate and thus cut through more tissue. The prostate in this figure is much exaggerated in size.

The operator glances about him to see that the water is running through the cooling apparatus; that the pipes are in a corresponding position on either side, thus showing that the beak is exactly behind the middle of the prostate; that the connection is made; that both cells have been thrown in, and that the cable contact fits well up on the pivot of the instrument. He then instructs the assistant to turn the black screw on the top of the

FIG. 7.—Cutting through the prostate.

battery in the direction indicated by the arrow. When this has been turned until the swinging hand on the amperemeter indicates forty amperes, it is probable that the blade has been heated sufficiently to begin; so, after

waiting a few seconds to make sure, the operator begins to turn the wheel of the instrument slowly, holding it steadily and watching the number of centimetres appearing on the scale, which indicate the length of the incision that is being made. This incision is usually about three to 3.5 centimetres (an inch and a quarter) long. The blade is then slowly glided back again by turning the screw in the opposite direction. The time required to make this incision is usually from a minute and a half to two minutes. The assistant then quickly reverses the black screw until the hand of the ampèremeter has swung back to zero (0) again. There is no need of doing this, however, as, by just unscrewing the contact screw on the cable attachment, the current can be broken and the hand will swing back to zero (0). There is, however, danger of injuring the knife in this way.

The beak of the instrument is then turned at right angles and caught in behind the posterior margin of the larger lateral lobe, and the screw is again turned by the assistant until the ampèremeter shows the number of ampères required, when the wheel of the instrument is turned until an incision of the desired length has been made, when it is again reversed and screwed back into place. The length of this incision is usually 2.5 to three centimetres, and the time spent in making it a minute and a half. The next incision is either through the roof of the prostate or the other lateral lobe. If through the other lateral lobe, the incision would be slightly shorter and requires just a little less time than the other. If through the roof of the prostate, the length of the cut would be about two centimetres, and the time required from a minute to a minute and a quarter. In making my incisions I generally follow the rules of those who have operated most frequently on these cases—that is, of making a posterior incision, an anterior one, and one through the larger of the lateral lobes, although in four cases I have simply made a posterior and two lateral incisions. It will be extremely interesting to me to know which of these two groups gives the best results. In another case I simply made a posterior incision. My reason for not making more incisions in this last patient was because my battery gave out, as I did not then know that it could not be used more than two or three times without being recharged. Care must be taken while doing this operation not to allow the patient to pull away from the instrument, but to always hold it in the same relation to him throughout the entire procedure. Naturally, if the elbow is kept firmly in place on the table, and the patient pulls back, as he often does, the instrument might be pulled away from the point where the cutting should be done and the incision might be made through the tissues which should not have been interfered with. If, then, the patient pulls away, the hand guiding the instrument should follow him in such a way that the instrument always remains in the same position. In one case operated upon, in which the pa-

tient's pelvis was elevated on a sand bag, he suddenly pulled away, allowing the concavity of the end of the instrument to ride over the convexity of the middle lobe, with the result that the heated blade that had already cut through the middle lobe, and was about to be pushed back, burned its way down through the floor of the membranous urethra into the perineal tissue. Accidents of this kind are liable to happen to any one, especially during the first operations, and should always be reported, as through them the surgeon learns what may happen, and it puts him as well as his readers on guard against such an accident occurring again.

Immediately after the operation the patient may be allowed to pass water, if he desires, and he should be put to bed. Patients are generally able to walk from the table to their beds, although it is safer to carry them.

The internal treatment consists in urinary antiseptics, diluents, and antispasmodics, if necessary.

As a diluent, water taken in large quantities is usually sufficient. If it is found, however, that the patient will not drink much, and that the amount of urine passed is below normal, its flow should be further stimulated by a mild diuretic, and for this purpose I am in the habit of giving a mixture of twenty grains of acetate of potassium, twenty minims of sweet spirits of nitre, in peppermint water, three times a day in a glass of water. As a urinary antiseptic, I generally give salol in ten-grain doses three times a day, or urotropin in the same strength, the latter preferably when the urine is foul and ammoniacal. Benzoate of sodium and benzoic acid in fifteen-grain doses are also of service.

The antispasmodics are codeine, morphine, and belladonna. These are given for frequency, pain, tenesmus, or burning. They may be prescribed singly or combined, and afford the patient a great deal of relief. Codeine may be given alone or in combination with belladonna, and perhaps benzoate of sodium. Morphine I rarely use, and then only for pain. It is very efficacious in combination with the extract of belladonna, a quarter of a grain each, in suppositories at night, in cases where there is a great deal of frequency, pain, burning, and tenesmus. The diet should be liquid for the first few days, then semisolid (soft), and full diet at the end of the week, if the patient has no rise of temperature and is feeling well.

If retention of urine occurs, as it frequently does, a catheter should be passed into the bladder and allowed to remain for from twenty-four to forty-eight hours. On withdrawing the catheter, if the patient is still unable to pass much urine, he should be catheterized regularly until the sloughs have been passed, when, if he is still unable to urinate, a second operation should be performed. If the patient has complete retention and nothing can be passed into his bladder, he should either be aspirated suprapubically or a perineal section performed.

If there is much hemorrhage, it can usually be

stopped by a hot irrigation, and, if not, a perineal section should be performed, after which a thick-walled perineal tube can be inserted into the bladder, around which gauze can be packed, thus making pressure between the sides of the tube and the cut posterior urethra.

The bowels should be moved by salines on the second day, after which they should be kept open for some days.

An elevation of temperature usually takes place on the night after operation or on the following day, rising from 100° to 105° F. This generally goes down to normal after the bowels have been moved, but I have seen cases with a temperature of from 99° to 102° for some weeks after the operation. In such a case the fever usually disappears after the sloughs have been thrown off.

Where the bladder and the kidneys are very much involved a continuous temperature may indicate a disease of the latter organs, which should then be treated accordingly. Extravasation of urine and perineal abscess might occur, but it is improbable, as the tissues are practically seared and sealed by the burning process.

To review the steps of the operation without comments and suggestions:

The instruments and apparatus required for the operation are: A soft-rubber elbowed catheter, a large hard-rubber hand syringe, and a small urethral hand syringe; a scalpel; a Bottini incisor; a fountain syringe and two pieces of tubing, one leading from the bag to the instrument, the other from the instrument to the receptacle on the floor; a galvano-cautery battery, or a transformer with a portable ampèremeter; glycerin, solution of eucaine (four per cent.), saturated solution of boric acid, and a cylinder of laughing gas.

Steps of the Operation.—The patient should be placed on his back on the table, the bowel having been washed out. The fountain syringe should be hung on the wall to the patient's left, connected with the incisor. The battery should be placed on a stool on the left of the patient and within reach of the operator. Pass a catheter lubricated with glycerin into the bladder and wash it out by means of a large rubber syringe until clean. Inject a eucaine solution (four per cent.) into the neck of the bladder and urethra by means of a urethral syringe. Inject six ounces of boric-acid solution into the bladder and allow it to remain. Pass the incisor into the bladder. If it will not enter readily, put a pillow under the hips. If, then, it can not be made to enter, give an anæsthetic (laughing gas preferably). Connect the incisor in the bladder by means of the cable with the battery. Turn the incisor so that its beak will point downward. Insert the left forefinger into the rectum and hook it over the base of the prostate. Pull the incisor forward until its tip is felt on or near the finger in the rectum. Withdraw the finger and take hold of the handle of the instrument with the same hand.

See that the contact screw is turned tight, and that

the water is running through the cooling apparatus. Throw in the two cells and turn on the current to forty or forty-five ampères. Turn the wheel until the knife has gone forward and backward through the floor of the prostate. Turn the instrument at a right angle and cut through the larger lateral lobe, and then turn it again at a right angle and cut through the upper or anterior part. Return the patient to bed. If followed by retention, pass a catheter and allow it to remain for one or two days. After-treatment: urinary antiseptics, diluents, and antispasmodics.

Judging from the cases upon which I have operated, this is the procedure for prostatic hypertrophy which exposes the patient to the least amount of danger, generally gives relief, and diminishes the amount of residual urine.

23 WEST FIFTY-THIRD STREET.

REPORT OF A NECROPSY IN A CASE OF ACROMEGALY,

WITH A CRITICAL REVIEW
OF THE RECORDED PATHOLOGIC ANATOMY.

By LOUIS J. MITCHELL, M.D.,

AND

E. R. LE COUNT, M.D.,

ASSISTANT PROFESSOR OF PATHOLOGY, RUSH MEDICAL COLLEGE, CHICAGO

PART II.

By DR. LE COUNT.

(Concluded from page 560.)

Anatomical Description.—The height is 4.5 centimetres, the transverse diameter is 3.7 centimetres, and the width 2.7 centimetres. When viewed from above, it presents a smooth, hemispherical projection, which, a little to the left of the centre, possesses a tuftlike bit of tissue resembling fibrous tissue. This smooth surface is covered by a limiting membrane, which has become somewhat wrinkled from the alcohol. The posterior surface consists of three rather distinct portions; above, the posterior surface of the knoblike upper part, a middle area covered by a thin layer of bone or calcified membrane, and below an irregular surface which has a torn appearance. These three portions are about equal in extent. The front is a continuation downward of the smooth upper surface. The base and lateral surfaces are ragged, as though torn away. The membrane covering the upper surface is continued for a short distance over the lateral surfaces. On either side in the groove at the base of the knoblike part are rather large-sized vessels which curve forward from behind. On section it is uniformly dense, with a smooth surface which shows absolutely no markings. Portions of the entire surface obtained from a median sagittal section were studied.

Histological Description.—The growth is made up almost entirely of cells which have every appearance of glandular cells. They possess either oval or circular nuclei; the nuclear membrane is not darkly with nuclear dyes, and here and there in the nucleus are many dark granules. These granules show no peripheral disposition, but are dispersed over a lightly stained nuclear sub-

stance. The nuclei vary considerably in size, as do also the cell bodies. The bodies of these cells are moderately granular; the eosin staining in them is quite uniform as to depth of color. These cells are regularly disposed in clusters, and this arrangement is found prevalent in all parts examined. The groups do not vary much in size, but toward the periphery they show a tendency to form *rows and tubules* (*italics ours*).

The grouping of these cells is much more regular than would be expected in a sarcoma which was made up of such large round cells. The cells forming a group are in contact. The cell body is too great in amount and too irregular in quantity and disposition for a sarcoma cell. In a round-celled sarcoma the protoplasm of the body is scanty. Occasional cells occur with the nucleus near one pole, and where row formation is marked the columnar character of these cells is very conspicuous. Nothing resembling caryocinesis can be found. Between these groups of cells occurs a scanty amount of connective tissue, in which small blood-vessels are sometimes present. There are no very large trabeculae.

In sections from the more central parts of the growth are some rather large areas filled with a granular *débris*, which stains slightly with eosin. No well-preserved red corpuscles can be found in any section, even in the blood-vessels, but a granular *débris* is present in the vessels. This granular material must represent poorly preserved blood, and the areas points of hæmorrhage. Blood frequently presents this appearance in alcohol-hardened tissues. The areas of hæmorrhage are very irregular, with ragged edges, and in places the cells at the edges have become dislocated into the blood.

The similarity of this description to that of other growths met with in acromegaly in the hypophysis, and recorded as examples of round-cell sarcoma, lymphosarcoma, adenoma, and hypertrophy, is unmistakable. The growth described above is certainly one of the largest on record (39.76 grammes). From this examination we can eliminate sarcoma at once, for the following reasons: The glandular type of the cells; the regularity of their grouping; the fact that the cells are in contact, and the gradual change of the cell clusters into more or less typical rows and tubule formations at the periphery; lastly, there are no atypical or embryonal blood-vessels seen. Whether the growth is to be considered as an adenoma or as the result of hyperplasia is of much less consequence.

The elements of the anterior lobe are certainly increased in number, and it is equally certain that their normal arrangement is not preserved. It therefore follows that the epithelial cells of the anterior lobe have proliferated and produced a large tumorlike growth, and it seems preferable to call such a condition hyperplasia rather than adenoma, if by the latter term is meant a true benign tumor representing some gland in structure. If this be accepted as an example of hyperplasia, it must be acknowledged that many of the other

large solid growths found in the hypophysis in acromegaly are instances of hyperplasia also.

One of the strongest arguments in favor of this view is the fact that the conclusions drawn from the study of many of these growths fluctuate between hypertrophy and adenoma.

Again, the conditions most frequently observed concern round cells. Schütte mentions adenoma as having been observed eight times, sarcoma nine times, and lymphosarcoma five times; Sternberg says adenoma has been found seven times, sarcoma five times, and large-cell sarcoma six times.

If these growths were examples of a tumor as malignant as we know round-cell sarcoma to be, why do we not have cases of metastasis? Certainly not from lack of adjacent blood-vessels. And why are the phenomena of cell division so common to sarcoma entirely lacking in the histologic descriptions? It must be conceded that hyperplasia and not true tumor is the condition of the hypophysis in instances where large solid growths have been found.

But acromegaly does not depend upon a hyperplasia of the epithelial elements of the anterior lobe, for numerous cases are on record in which no symptoms of acromegaly were evident, and yet similar changes in the hypophysis to those just considered were found present. Reference will be made to but two:

Breitner described a growth the size of a pigeon's egg which filled the entire sella turcica, causing a depression in the brain and pressing upon the optic chiasm and nerves. It was covered by a smooth glistening membrane, and was not adherent to the brain. Microscopic examination showed it to be a simple hyperplasia of the hypophysis, with colloid degeneration. The author calls it adenoma. Breitner reviews the literature very thoroughly, and notes that many similar tumors have been described. More recently Hippel describes a large tumor of the hypophysis from the anterior lobe. It produced necrosis of the sella, and extended to the third ventricle. It was very soft, and was found microscopically to present a gradual transition between a peripheral portion resembling the normal anterior lobe and the tumor proper. Hippel does not name the growth because he was uncertain as to its nature, a similar confusion to that seen in conclusions drawn from studies of the hypophysis in cases of true acromegaly.

Acromegaly can not be dependent upon an abolition of function alone—a function the very existence of which remains to be proved—for the hypophysis is occasionally the seat of granulomata. Hektoen has collected five cases of gumma of the hypophysis, to which he has added a sixth. He also mentions two questionable instances of tuberculosis.

Any explanation of the pathogenesis of acromegaly must take into account a relationship between the hypophysis and the thyroid gland. This statement is authoritative, as will be seen from the following evidence:

Hofmeister, Stieda, Gley, and Goldberg, following Rogowitzsch, have found that the hypophysis becomes enlarged when the thyroid gland is removed. The work of Goldberg was done to determine the influence of the thyroid upon the development of the body, and he maintains that the hypophysis is one of the organs which influence the development of the body.

Boyce and Beadles, in a case of myxedema with atrophied thyroid, found a compensatory enlargement of the hypophysis; in a case of sporadic cretinism with entire absence of the thyroid, the hypophysis was also enlarged.

Bourneville and Bricon, Dolega, Niépce (five cases), and Osler have reported cases of cretinism in which either absence or atrophy of the gland was accompanied by enlargement of the hypophysis.

Schönemann, in a systematic examination of the hypophysis and thyroid in a hundred and twelve bodies, death from various causes, was led to believe in a close relationship between the two organs. Boyce and Beadles also examined the hypophysis in a hundred instances of death from various causes, in which the thyroid was unchanged. They found a great uniformity in the structure of the hypophysis.

Kocher reports finding the hypophysis enlarged in a case of death from cachexia strumipriva; the thyroid had been removed by operation. Pisenti and Viola, in a woman who died from struma fibrosum, report increased colloid formation in the thyroid gland. Comte examined the hypophysis in thirteen cases of death from, or accompanied by, goitre; it was enlarged in all. From the fact that the thyroid undergoes hypertrophy in pregnancy, and from observing enlarged hypophyses in six cases of death from pregnancy or its sequelæ, he concludes that a relationship exists between the two organs. He also found the hypophysis enlarged in a case of myxedema. Grön has reported a like occurrence, and Murray has collected six cases where acromegaly and exophthalmic goitre occurred together.

The hypophysis occupies a most peculiar position anatomically, surrounded as it is by bony walls, and held in position by the dura, which not only serves in places for periosteum, but also is intimately adherent to its capsule.

Quain states that "the pituitary body has a special prolongation of the dura mater completely inclosing it except above, where there is a small aperture for the passage of the infundibulum." Poirier gives the following description: "It (the hypophysis) is fixed in its position by the diaphragm, known under the name of the pituitary tent of the hypophysis, or tent of the hypophysis, and by the prolongations of connective tissue which unite its capsule to the dural covering of the fossa." Concerning the sella turcica, we find the statement that "the sella turcica is closed by the pituitary tent (operculum of the hypophysis, diaphragm of the sella turcica), a layer of dura mater which forms a roof

for it; on the anterior and posterior walls the dura forms the periosteum for the bone; the lateral walls of the cavity are formed by the dura, which rises up and closes in the space between the anterior and posterior clinoid processes."

From these quotations it is apparent that the hypophysis is unique in being so completely inclosed by firm walls. Another anatomical peculiarity of this organ, which has likewise been overlooked in the consideration of the pathologic changes to which it is liable, is its relation to blood-vessels. In front of it is the wide coronary sinus; behind, the posterior branch of the coronary sinus; and below, under the anterior lobe, many sinuses forming the intercavernous network.

It may not be amiss to ask what would occur in an organ surrounded by such fixed walls and so many venous sinuses should enlargement of the bony cavity take place primarily. The answer that naturally suggests itself is an œdema *ex vacuo*, possibly hemorrhages.

The large number of cases of acromegaly in which the enlarged sella turcica was found occupied by a fluid or semilfluid mass certainly supports such a supposition.

Caton and Paul, soft, dark, and dotted with hemorrhages; Brooks, soft and jellylike; Osborn, a pulpy mass; Holsti, very soft and semilfluid; Fritzsche and Klebs, a soft mass, liquid in the centre; Thomson, very soft and pulpy; Dallemange (1), friable; Hansemann, medium soft; Bourneville and Regnault, soft and gelatinous; Roxburg and Collis, soft and vascular; Linsmayer, a pulpy mass; Fränich, a walnut-sized cyst filled with blood; Dana, apparently somewhat cystic—serum and blood escaped; Claus and Van der Stricht, on section contained a fluid; Boltz and Fraenkel, soft in consistence; Bailey, red, very soft, some semilfluid contents escaped; Furnival, converted into a cyst; Johnstone and Monroe, softer than the brain; Hunter, red and very vascular; Comini, softened; Strümpell and Zenker, microscopic areas of hemorrhage; Sigurini and Caporiccio, soft; Mitchell and Le Count, a pulpy, semilfluid mass; Dalton, much softened.

Much of the obscurity surrounding the pathogenesis of acromegaly—at least the prevailing connection between acromegaly as a disease and the changes in the hypophysis as its cause—can be attributed to the difficulty of experimentation. The inaccessibility of the organ is not the least obstacle. It is certain that experimental work should take into consideration, if possible, a primary enlargement of the sella turcica.

In concluding this *resumé* of the pathologic anatomy of acromegaly, the following propositions which directly concern the elucidation of its pathogenesis seem to have acquired prominence:

1. The cases of acromegaly associated with true tumor of the hypophysis are certainly not as numerous as has been heretofore supposed.

2. There is not as much connection in the pathologic condition of the hypophysis as there is in an enlarge-

ment of the heart, the thyroid gland, or the sella turcica.

3. Acromegaly does not depend, at least not solely, upon abolition of any function of the hypophysis.

4. A relationship between the thyroid gland and the hypophysis has already been amply proved.

5. It is not at all improbable that proliferation of the histological elements of the hypophysis may be instituted in some cases by a primary enlargement of the sella turcica; in other cases, an oedema or hæmorrhage *ex vacuo*.

6. We have no reason for supposing that enlargement of the sella turcica may not be as constant an occurrence in acromegaly as the changes in other bones, or that it might not take place from a similar cause or causes.

PROTHYMIA:

A NEW FACULTY AND ITS LOCALIZATION.

By WALLACE WOOD, M. D.

SOME four years since I began preparing the brains of domestic animals by the dry process. The following is the method: I pass the specimen successively through nitric acid, bichromate, carbolic, glycerin, and oil of cloves. I then paint it, varnish it, and reproduce six copies in plaster and in photography. My studies have been chiefly swine and rabbits, felines and canines, horses, and some fifty cattle. The collection so formed I took in part to Europe last summer in order to compare these brains of domestic animals with the two collections of the brains of wild animals, one in the College of Surgeons, London, the other in the Jardin de Plantes, Paris. At both places I was offered every facility. At the Jardin de Plantes I was given a special room, and the jars were opened for my inspection. I was also presented with copies of the brains of two lions, one lioness, one American black bear, and one Indian panther. For such kindness as this, what thanks are adequate? I was much gratified at obtaining these specimens. I was, for instance, able to compare the brain of an Indian panther with that of the Newfoundland dog, and the brain of the African lion with that of an old New York working lion of very good breed that had died in harness, a specimen that had given me no end of pains and cares. By a six months' study of these two collections, comparing and contrasting

them with my own, I seemed to find further proof of the existence or localization of a cerebral faculty with which I had already been strongly impressed while working upon the domestic animals only.

In making my collection the region to which I had directed all my attention was the inner-under surface; the point, therefore, which is the subject of this brief article was unlooked for and was gradually forced upon me. I noticed an extraordinary roundness and fullness in the coronal or metopic region of the hemispheres of certain cows and horses contrasting in a surprising way with the same region in other animals. I had this same roundness, this forwardness of front, forced upon my view when looking at the mesial surfaces of the brain of the Newfoundland dog, the terrier dog, and the sheep.

Following are the observations:

The metopon, or anterior metopic lobule, in the Newfoundland dog presents an appearance of swelling forward, or pushing or surging forward, while that of the pug dog shows a contrary tendency: it seems to slope or sag and hold back. This same forwardness of line or curve in the horse is so strong that, comparing it with the run of brains in the animal series, it seems almost, as it were, tremendous or "prodigious."

This same willingness to come forward I found in the mesial metopic line of the black-and-tan dog, and this same unwillingness to come forward in the brain of *Felis domesticus*, the cat of either sex.

The grand arch line of the brain of cats, as seen from the mesial surface, shows a back-upwardness, while that of good dogs shows a forwardness or forward-upwardness.

This round-coming form of the coronal struck me first in the cerebrum of the Newfoundland dog, next in the cow and horse. I have thought that the left hemisphere showed it more than the right; it is "always" the left hemisphere, however, that is typical. This coming-round form, this willingness to come forward in the curve, I found prominent in the sheep and wanting in swine. The brain of the sheep comes forward willingly, the brain of the swine comes forward unwillingly.

The normal or native appearance of the brain of a wild animal, and of many or most domestic animals, is that of a life pulling or arching itself in a direction backward-upward. The form that I am seeking to describe seems a contrary tendency or effort.

If we essay to translate this metopic or coronal curve into the language of psychology, would not the quality be *eunoia* or *prothymia*? This willingness to come forward, is it not mental as well as cerebral? The horse comes forward willingly to be harnessed; the cow comes forward willingly to be milked; the dog comes forward willingly to fetch a stick from the water, and the sheep comes forward willingly to have its wool cut or its throat cut, or whatever you like.

We turn now to the contrary mental disposition: the

pig comes forward most unwillingly, the domestic cat comes forward always with a mental reservation. The temper of the pug dog is, I believe, quite unlike that of the Newfoundland dog. As for the wild cat, the lion, the panther, or the wolf, suffice it to say here that they do not come forward with their metopic lobule or mesial metopic curve, but with something else, not with the metopic centre, but with another centre. It seems to me that what I have found is true. As a pupil and follower of Broca I know how hard it is to ground with scientific certainty even the smallest point, but I believe this can be grounded.

164 FIFTH AVENUE.

A SUMMER FALLACY.

By RAMSAY MACNAUGHTON, Esq.,
MANCHESTER, VT.

CITY dwellers will soon be saying they are going up in the mountains. This is correct, if we believe language was meant to conceal thought. In this case it seems to indicate a lack of thought. Many would be dumbfounded if they realized the fact that they went *down into* the mountains, and were but a few hundred feet higher than their more accurate acquaintances who say they go down to the sea.

Strange as it may seem, those who go down, frequently attain more and better air and sunlight than those who think they go up. The latter are too often found down in the howels of the earth, in deep narrow valleys, by chilly streams, shut in from sunlight by overhanging mountains.

No doubt many are benefited; for summer time, outdoor life, exercise, and pleasure will accomplish that anywhere, and an inland place will suit some as the seashore will not. But Americans have not yet, like the Europeans, learned the greater advantages and delights of elevation.

Neither is the medical fraternity to blame, for until the recent advent of the contour maps of the United States Geological Survey, elevations were rarely and not reliably given. These remarkable maps are in sheets of thirteen by seventeen inches, representing five by seven miles, and can be had on application for five cents each.

No physician can afford to be without these sheets for ready reference of all those localities that he is inclined to send patients into. Dots on the maps indicate the exact position of every habitation, whether it be sanitarium, health resort, or private dwelling.

The minute lay of the land is given, disclosing faithfully any hidden marshes or low wet spots, and the course of every little brook and large bodies of fresh water, also the slope of the land and its exposure. Heretofore those seeking summer patronage in places having no elevation claimed it because it was impossible

to disprove it, especially if the air seemed good and the place healthy.

Persons who unquestionably live at a moderately high elevation have vague ideas of thousands of feet, maintaining the elevation to be as much as five thousand, though rarely reaching fifteen hundred.

The limit of inhabited places back of the Hudson ranges below nine hundred feet, and is usually from five to six hundred, and the air is merely fresh and pleasant, never bracing. The Litchfield Hills are about a thousand feet, with good and often bracing air.

The Berkshire Hills have a bracing air and twelve hundred feet elevation, which in the village of Mount Washington, near Great Barrington, attains two thousand feet. Here air, woods, and other conditions are not excelled by the Adirondacks, Catskills, Green, or White Mountains.

Too many of the places in these last four localities have no elevation beyond a few hundred feet, though well back in the mountains and reached by ascending roads, until a final pitch of a mile or two brings the traveler down into a hole in the ground. The most favored places in the Adirondacks halt at eighteen hundred feet, the air and the influence of woods being very fine.

Catskill places, as a rule, do not come up to a thousand feet, and are too often shut in. A fair number range up to fifteen hundred, and three are at three thousand feet.

Except on back-mountain roads, not yet frequented, the Green Mountain places range a thousand feet, which, with vast spruce woods and bracing air, combine conditions best suited to most people. The tonic and stimulus derived does not surcharge the system or produce wakefulness, discomfort, or after-reaction.

The White Mountains enjoy these features with somewhat higher elevations, except the approaches to them, where they amount to nothing.

A mountain resort needs few if any trees; the more open and exposed and away from water the better.

Europeans have long attached great significance to this matter of elevation, which is known and studied thoroughly by the medical profession abroad, and is never slighted.

No place in Switzerland, or other mountain health resort, is without its elevation put officially in a conspicuous place and incessantly advertised by all lines of business. In Switzerland one can, by easy changes and stages, pass up five hundred feet at a time, and spend weeks or months getting acclimated to the final elevation of San Moritz, Davos, and a few other places of six thousand feet. Higher inhabited elevation can be found only at inns and hospices on tops of mountain passes, which are primarily places of refuge, and the sojourner is expected to stop only overnight. These places are situated at an elevation of from eight to ten

thousand feet. Many can not stand several thousand feet without all manner of temporary functional ailments, with every indication of considerable ill health. Sleeplessness is a common discomfort, and often one must hang up a sheet rung out in water or sprinkle the bedroom before sleep is possible.

In this country we have no such conditions until one gets well up into the Rockies; there the very high elevations and peculiarly rarefied atmosphere are greatly beneficial to many, but if indulged in for too long a time they will create nervousness and conditions supposedly common only to low places and damp climates, such as rheumatism and catarrh, which are prevalent.

A CASE OF CHRONIC INFLAMMATORY INDURATION OF THE CORPORA CAVERNOSA.

By WILLIAM R. COCHRANE, M. D.,

PROFESSOR OF PATHOLOGY IN THE TENNESSEE MEDICAL COLLEGE, KNOXVILLE.

THE rarity and the comparatively few cases on record of this condition lead me to report the following case which recently came under my observation:

A. B., married; native of United States; professional man; general history good; family history good. Date of examination, March 3, 1899.

The attention of the patient was first called to the existing condition some eight weeks ago by noting a slight deformity of the penis while in a state of erection. This deformity consisted in a bowing or arching of the organ, the point at which the bending occurred being located a few centimetres posterior to the glans on the dorsum of the penis. This erectile deformity, slight at first, increased gradually and persistently until at date of examination a pronounced "bird-neck" appearance was apparent during erection.

Examination shows an oval, flattened, indurated mass, measuring about a centimetre in width by 1.5 centimetre in length, situated about three centimetres posterior to the corona of the glans on the dorsum of the penis. The induration is in the median line, beneath the integument, which shows no evidence of implication, and is freely movable. From this oval mass a smooth, rounded prolongation extends backward to the root of the penis. No evidence of the presence of the enlargement is apparent upon inspection of the flaccid organ, and none while in a condition of erection, beyond the deformity alluded to.

The indurated mass occupies and evidently consists of a thickening of the tunica albuginea, with mesal line, including the septum, and probably to a slight extent the corpora cavernosa. The mass is firm, and gives an elastic, semi-articular sense of resistance when firmly grasped between the fingers.

The patient gives no history of any other period of the disease, erection and nocturnal emission giving merely a feeling of discomfort.

No pain or tenderness or other evidence of inflammation is obtainable. No history of stricture, priapism, gonorrhoea, or syphilis. General health about ordinary examination negative.

Therapeutical Notes.

The Chronic Dyspepsia of Children.—Dr. E. Decheri, in a Paris thesis (*Archives de médecine des enfants*, April), gives the following formule:

1. R Sodium bicarbonate, }
Calced magnesias, } each, 3.5 grains;
Benzonaphthol, }
Powdered nux vomica 0.3 of a grain.
M. Such a powder to be given twice a day for ten days.
2. R Sodium bicarbonate 3.5 grains;
Neutral bismuth sal- }
icylate, } each, 1.3 of a grain;
Benzonaphthol, }
Powdered nux vomica 0.3 " "
M. To be used in the same way (in cases of diarrhoea).
3. R Glycerin 15 grains;
Alocs 1.5 grain;
Extract of belladonna... 0.15 of a grain;
Cacao butter a sufficiency.
M. For a suppository (in cases of persistent constipation).
4. R Calomel 0.15 of a grain;
Powdered anise seed .. 0.75 " "
Powdered nux vomica 0.077 " "
Sugar of milk 7.5 grains.
M. One such powder three times a day (for tympanites).
5. R Oil of sweet almonds 20 parts;
Tincture of nux vomica 2 " "
M. To be rubbed upon the abdomen.

Prevention of Hereditary Syphilis.—A. Fournier, in a Paris thesis, 1898 (*American Journal of Obstetrics and Diseases of Women*, March), advises mercurial treatment of the mother during pregnancy, even though she is healthy, if the transmission of syphilis from the father is feared. This method has proved successful in cases in which the father was affected with syphilis while the mother was not. Treatment should be begun as early in the pregnancy as possible, and should be administered twenty days in each month, then the administration of mercury should be suspended for ten days.

Calcium Permanganate in the Treatment of Pultaceous Angina.—Mommarsion (cited in the *Klinisch-therapeutische Wochenschrift* for April 2d) recommends painting the affected parts every three hours (twice during the night) with this solution:

- R Calcium permanganate 1.5 to 3 grains;
Water 300 "

M. Each application should be preceded by gargling with a four-per-cent. solution of boric acid, as hot as can be borne, and by gentle efforts to detach the false membrane.

The Action of Heroine. Dr. B. Turnauer (*Wiener medicinische Press*, March 19th; *Klinisch-therapeutische Wochenschrift*, March 26th) remarks that heroine, the diacetic acid ester of morphine, has a sedative action on the respiration even in doses only one tenth as large as those of codeine, although the fatal dose of each is the same. He has used heroine in the form of

powder (0.015 of a grain, with sugar) as a rule three times a day, and in that of a solution ($\frac{1}{3}$ of a grain of heroine to half an ounce of cherry-laurel water), from fifteen to twenty drops at a dose, not more than two doses to be given in the course of a night. He has used the remedy on forty-eight patients with phthisis, bronchitis, emphysema, or various forms of dyspnoea, with the following results: In many cases it failed or was less effective than morphine. It begins to take effect in from ten to thirty minutes; the disposition to cough soon subsides, then languor and drowsiness supervene. This lasts for two hours. Subjective dyspnoea is decidedly lessened. The patient becomes accustomed to the drug, but no unpleasant effects are observed to follow the discontinuance of its use. Nausea followed its employment in two cases. It is an efficient remedy for cough even in persons habituated to narcotics.

For Dipsomania.—The *Cronica medica* for February 15th gives the following:

- R Apomorphine 3 grains;
Tincture of calumba 450 "
Tincture of capsicum 15 drops;
Tincture of nux vomica 450 grains;
Compound tincture of cinchona 750 "

M.

A small spoonful to be taken after meals in a little water.

Credé's Ointment in the Treatment of Phlegmasia Dolens.—Dr. Peters (*Deutsche medicinische Wochenschrift*, March 9th; *Klinisch-therapeutische Wochenschrift*, March 26th) reports a case in which somewhat more than four hundred grains was used with a favorable result. There were no phenomena of argyrosis.

An Ointment for Hæmorrhoids.—A writer in the *Nord medical* for March 15th gives the following formula:

- R Cocaine hydrochloride 15 grains;
Ergotine 60 "
Ichthyol 75 "
Calomel 45 "
Vaseline, { each 225 "
Lanolin, }

M. A portion as large as a small nut to be inserted into the rectum after an evacuation.

Brewer's Yeast in the Treatment of Leucorrhœa.—Landau (cited in the *Klinisch-therapeutische Wochenschrift* for April 2d) has used yeast in about forty cases, and for the most part with excellent results. Through a speculum he injects from ten to twenty cubic centimetres against the fundus of the vagina, and then inserts a tampon. The tampon is to be retained for twenty-four hours. This is repeated every second or third day. In two cases itching of the vagina was complained of, but there were no other unpleasant effects. The yeast is kept on ice and obtained fresh every three days.

An Ointment for Sciatica.—The *Riforma medica* for March 25th gives the following as Hirschhorn's formula:

- R Oil of hyoscyamus, { each 5 parts;
Oil of turpentine, }
White wax 2 "
Simple ointment 40 "

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 29, 1899.

THE STERILIZATION OF MEN.

IN our issue for January 28th we published an editorial on The Sterilization of Women, referring therein to a new method of procedure for effecting that end which was advocated, and has been practised, by Professor Spinelli. We were moved to consider this matter by the tendency now becoming, as we think, unfortunately common to aim at the legislative restriction of marriage, with a view to lessen the danger to the community arising from the procreation of diseased and degenerate offspring. This danger is undoubtedly a real one, and if we are honestly and firmly opposed to all such restrictive marriage legislation, it is not because we are not in hearty accord with the object aimed at, but because we think that the proposed means would create evils wider, more far-reaching, and more deplorable than even the results against which they are directed. In our editorial already referred to, as also in a subsequent one on The Disquieting Frequency of Criminal Abortion, which appeared in our issue for February 25th, we took occasion to refer to what we consider to be the real aim and purpose of the love union of a man with a woman—viz., the perfect, intimate, and complete companionship, mental, emotional, and physical, between two persons of opposite sexes who are, or should be, the perfect complements of each other, and without which association the life of both is liable to be forever incomplete. In using the word "perfection" in this relation we are, of course, well aware that in this existence at any rate such perfection is not attainable; but that is no reason why the ideal should not be aimed at, for the higher the aim the nearer to perfection will the result be, even though, as in the case of the mathematician's " x to infinity," it can never be completely realized.

We have contended that with the union of the man and the woman *per se*, the community has nothing to do. It is only by virtue of its potential results that the community acquires any right to intervene at all. Now, it is conceded on all hands that the unrestrained reproduction of the physically or mentally diseased or degenerate is a menace to the welfare of the community; but, as we have stated, "we can not but feel that there

are numberless instances in which a safe and easy method of rendering women sterile, when pregnancy would be a source of more than ordinary danger to the individual, or a direct wrong to the community, is far better than a harsh prohibition of that union without which, when rightly entered upon, the highest aim and incentive of life is incomplete, and in many cases life itself becomes a burden and a despair."

The sterilization of women, however, would be properly a solution of only half the problem. When the source of danger is to the woman, her sterilization is of the greatest moment to herself. When, however, the danger threatens the community, it is obviously only reasonable to place the burden of protection against it on her when she is the element in the union through whom the menace is likely to come. It is quite conceivable that a woman, herself perfectly healthy, may love and desire to enter into marriage with a man whose offspring, should he have any, would be most undesirable acquisitions to the race. Doubtless, in many instances, she would be quite willing to forego the joys of maternity rather than lose the companionship of the one man who is, or at any rate whom she believes and feels to be, her true mate, and would be ready to that end to submit herself to any necessary process. But there is another side to that question. The marriage may not turn out as was expected. The husband may prove dissolute, love be destroyed, and the law put an end to the relation; or, even if the union proves all that was hoped for, the husband may die while the wife is still in her prime and capable of forming a new attachment, in regard to which no reasons against procreation can be urged; and what is to be done then? She can not be "resexed," so to speak.

It is therefore plain that the sterilization of women, even if it can be safely and securely effected, is a remedy for only half of the evil. The question is what to do in the case of the other half.

Now, while a woman can be rendered securely sterile without affecting her capacity for the physical part of her union, all the plans hitherto suggested for sterilizing the male have been open to the objection that in accomplishing that end they rob him also of his capacity for the physical part of his union with the woman.

At this juncture we have read with great interest an article by Dr. A. J. Ochsner in the *Journal of the American Medical Association* for April 23d on the Surgical Treatment of Habitual Criminals. Dr. Ochsner relates two cases in which, for certain morbid conditions, he resected the vasa deferentia on both sides through an incision just below the external inguinal ring. Of the effect upon the patient, he states with regard to

the first case that twenty months after the operation the patient was perfectly well, and his sexual power, which had been somewhat impaired before the operation, was fully as good as at any time during his life. With regard to the second case, he asserts that the patient has been perfectly well ever since, and has found no impairment of his sexual desire or power. He further refers to recorded observations of analogous cases in which complete obstruction of the vasa deferentia as a consequence of gonorrheal inflammation, although the subjects were necessarily rendered sterile, did not result in any lack of sexual inclination or power. Dr. Ochsner's suggested operation consists of an incision, made with thorough aseptic precautions and under local anæsthesia, in the direction of, and directly over, the cord down to the vas deferens and not exceeding one inch in length; the isolation of the vas deferens for the distance of half an inch; its ligation with catgut and division half an inch below this; the closure of the wound with a buried catgut stitch; and the application of a collodion dressing. It can be performed, he says, in less than ten minutes, without pain, and with practically even no subsequent scar.

Dr. Ochsner's main argument from these cases is a plea for the employment of such an operation as a means of dealing with certain criminals; but should it fulfill all that it promises, it seems in conjunction with Spinelli's operation to shed a ray of light on the dark paths, and to promise a means whereby less cruel, and in our opinion less unjustifiable, measures for protecting the race against the procreation of the diseased and the degenerate may be sought, than the arbitrary and unwarrantable one of robbing individuals of the whole of the greatest blessing of life, viz., the "glorified companionship of matrimony," in order to obviate the possible results of one function thereof.

There is another consideration also which must be reckoned with in this matter. The progress of scientific observation is rendering it clearer all the time that in some fashion, whether from nervous influence or by their internal secretions, glands like the testicles and ovaries are intimately connected with the character and constitution of the individual, and that their excision has a marked and permanent effect upon the personality. For this reason, therefore, any measure which will do away with the necessity of their removal in such cases is to be welcomed.

Of course we are only on the threshold of this inquiry. But we think that the men who demonstrate the feasibility and certainty of any safe means for effecting the sterilization of both men and women will do more good to the race, without inflicting harm or injus-

tice on individuals, than the well-meaning but, in our opinion, unwise promoters of antimarriage legislation.

NERVE-STRETCHING APPLIED TO THE SOLAR PLEXUS.

It seems that the surgeons have not yet exhausted the territory which they think they can invade to the advantage of the patient. Close upon operative procedures on the cervical sympathetic for exophthalmic goitre comes the proposal to attack certain trunks of the solar plexus for the relief of various functional disturbances of the abdominal organs. In *Lyon médical* for March 26th M. Jaboulay declares that there is a series of affections of the pancreas, the liver, the spleen, the kidneys, the suprarenal capsules, the aorta, and the intestine which denote abnormal action of the abdominal sympathetic system. They are connected, he says, with that malady which is so frequently the pendant of exophthalmic goitre in neuropathic patients, characterized by arterial pulsation in the scrobiculus cordis and by enlargement and paresis of the intestinal coils.

His mode of intervention is as follows: Through a median incision of the abdominal wall the pylorus is drawn down, and the abdominal aorta is sought for with the left index finger. The celiac axis and the renal arteries are readily detected by their pulsation; then with a grooved director the celiac axis and the fore part of the aorta are denuded in the neighborhood of the tripus Halleri and downward by the side of the superior mesenteric as if one were about to perform ligation. This process of denudation suffices to make impression enough for the purpose on those branches of the solar plexus which cross in front of that portion of the aorta after having been given off by the semilunar ganglia, and preside over the functions of the stomach, the intestine, the liver, the pancreas, the kidneys, the spleen, and the suprarenal capsules.

Thus far, M. Jaboulay has had occasion to practise his operation only once, in the case of a woman who had undergone surgical intervention five times on account of pyosalpinx and hemorrhagic metritis following parturition. He intimates that her condition was ameliorated by his procedure, but he attaches no importance to that fact; the operation, which was done on the 28th of January, 1899, is of interest, he remarks, solely as demonstrating the feasibility of such treatment in really grave cases. This woman had epigastric pulsation and intestinal enlargement. We are not told to what extent she was improved by the operation on her solar plexus. M. Jaboulay seems to think that in such cases as he refers to the "abdominal brain," as the plexus was

formerly called, is in a state of overactivity; it must rest with the physicians, he says, to select the instances in which the intervention he describes would be likely to be of service.

TETANY AND HYSTERICAL PSEUDO-TETANY.

It is not a little remarkable that it must still be said of an affection so sharply characterized as tetany that its very existence, apart from hysteria, is denied, or at least doubted, by men who are known as excellent observers, including so astute a clinician as Gilles de la Tourette. It is very satisfactory, therefore, to find von Krafft-Ebing (*Prager medicinische Wochenschrift*, April 8th) quite outspoken in the declaration that there is no neurotic affection on a firmer diagnostic foundation than tetany. He accounts for the skeptical attitude of many of the French physicians by the fact that tetany is rare in Paris, whereas hysteria is rife in that city, as in all centres of culture.

He gives short histories of five cases of pseudo-tetany that he has observed. In not one of them was Erb's sign present, and he insists that that test is a sure mark of distinction between tetany and pseudo-tetany. He adds that in no case of true tetany on record, save Weiss's, cited in von Frankl-Hochwart's monograph, has there been wanting the presence of heightened excitability of the motor nerves, especially the ulnar nerve, under the galvanic current. Since in no other disease of the nervous system, certainly not in hysteria, is this condition found so pronounced as in tetany, he goes on to say, Erb's sign must be held to be the most striking means of distinguishing the real disease from its hysterical counterfeit, although there are various other means that ought generally to serve every purpose. True tetany, von Krafft-Ebing declares, should be distinguished without difficulty from hysteria, the only disease that mimics it.

A COUNTRY DOCTOR.

In our issue for April 15th we quoted some exquisite verses To a Certain Doctor that most feelingly portrayed the true physician's trustful crown. Such sentiments as are therein expressed have ever been theoretically, and in many instances practically, the highest and most gratifying reward of the high-minded medical practitioners in all ages and climes. It is with great pleasure that we have recently read what we may perhaps be allowed to call a prose poem on A Country Doctor, written by Dr. Thomas Hall Shastid. That this admirably written tribute to a hardworking, heart-hearted, great-souled physician, toiling humbly, but not too remuneratively, yet with all his heart and soul in his work, and still finding time to keep up some of the attainments of the classical scholar, is paid to the author's own father is no detriment, but rather reflects

on the son some of the honor thus accorded to the father. If the country doctor whose honorable career is here recorded has cause for greater gratification at anything than that his career has been such as is described, it is that he has been able to inspire his son with such a reverence for it as shows plainly through every line of this little book. The book, illustrated with admirable etchings, is published privately by the author for his friends; but the previous appearance of the sketch in the columns of the *Journal of the American Medical Association* for February 27, 1897, justifies us in referring publicly to it as a pleasing addition to that literature of the "doctor to fame unknown," whose archetype will long be remembered in Ian Maclaren's Dr. William Maclure.

THE HUNDREDTH ANNIVERSARY OF THE MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

The meeting which has been going on in Baltimore this week has been as interesting and satisfactory as everybody expected who knew the physicians of Maryland. The programme was unusually rich in papers and demonstrations by men of eminence: the president's address, by Dr. Chew, and Dr. Keen's address were impressive to a degree that could not have been surpassed; the medical schools and hospitals of Baltimore contributed most profitable clinics and exhibitions; and Baltimore hospitality was at its best. One could not ask for more. We congratulate the faculty on its ever-increasing vitality.

TUBERCULOUS INFECTION IN RITUAL CIRCUMCISION.

THERE seem to be good reasons why ritual circumcision should give rise to tuberculous disease oftener than to syphilis among the strictest of the orthodox Jews, as is briefly set forth by Dr. Lubowski in the *Monatsberichte über die Gesamtleistungen auf dem Gebiete der Krankheiten des Harn- und Sexual-Apparates*, iv, 4, 1899. He is commenting on an instance reported by Dr. Neumann, of Vienna (*Wiener klinische Wochenschrift*, 1899, No. 6), of tuberculous infection conveyed by a peritonist who infected six children in the course of six months. Among the poorer classes of the orthodox Jews, says Lubowski, the old custom of checking or diminishing the hemorrhage by sucking the penis is rigidly adhered to, and the sucking is done by the circumciser himself or by some other person, especially a very honorable and elderly man; and it is in just these circles of the Jewish population that tuberculous disease is particularly rife, while they are practically free from syphilis.

HABIT MADE TORTICOLLIS.

BRISSAUD has described a form of torticollis which he regards as "mental" in its origin, that is to say, taking its origin in an enfeeblement of the will due to a state of mental depression. Dr. F. P. S. Ober (*Manifesto moderno*, 1898, No. 3; *Presse médicale*, April 5, 1899) has lately recorded a case in which a melancholic woman passed almost the whole of her time with her wing or knitting near a window situated on her right, and, being given to looking out there, the window frequently found her face so that her face was habitually turned to the right, and that she could not face straight ahead without turning her head with her hands.

THE PASSAGE OF DRUGS INTO THE SYNOVIAL FLUID.

THE actual invasion of a rheumatic joint by such a drug as salicylic acid or potassium iodide may be the *modus operandi* of the medicament in alleviating the manifestations of rheumatism. So, at least, Dr. Gaglio (*Archivio di farmacologia e di terapia*, v, 1898; *Deutsche Medizinal-Zeitung*, April 3, 1899) hints. In experiments on dogs he has found both these drugs in the synovial fluid after their ingestion by the mouth or their subcutaneous injection, but only for brief periods.

ICE MASSAGE.

DR. WILLIAM EWART, in the *Lancet* for April 8th, after considering the various modes of employment of heat and cold as therapeutic measures for the relief of pain, records three cases of painful joint affection with severe constitutional disturbance in St. George's Hospital, London, in which instant and marked relief, followed by permanent improvement, was obtained by gently rubbing the inflamed and painful parts with a small block of ice held firmly in the hand with flannel. Considerable local coldness was felt by the hand, and the patient experienced a sensation of coldness and numbness with freedom from pain. These sensations lasted in the first case for three quarters of an hour, and were followed by an internal glow resembling the pleasant warmth felt from sitting in front of a bright fire. The patient described the glow as reviving the feeling within the joint and destroying the pain, and as entirely differing in character from the hot pain with dragging feeling which constituted his special suffering. This treatment was used in all three cases after all ordinary methods had failed, or had even aggravated the patient's condition. This method differs from Arnott's direct application of ice, Esmarch's continuous use of ice-bags, and Kinnear's spinal ice-bag. The remarkable histories of the cases described would, we think, warrant its wide trial.

THE EFFECTS OF BILE ON SEPTIC PROCESSES.

BILE is commonly regarded as an antiseptic. By experimental researches Mosse (*Zeitschrift für klinische Medizin*, xxxvi; *Centralblatt für innere Medizin*, April 8th) has been led to conclude that, while for a time it is capable of inhibiting the development of fermentative and putrefactive agents in mixtures that are free from bacteria, if that development is once set up it seems rather to favor the decomposition induced.

A JUVENILE SURGEON.

MR. EDMUND OWEN, of London, has taken some pains to let it be known that he is a stickler for precision of speech. A few months ago he expressed his horror of the word *trauma*, which he stigmatized as having been imported from America. He was in error in making that statement, but the error does not detract from the genuineness (but utter groundlessness) of his disgust for the word. We have since seen further evidence of Mr. Owen's earnestness as a reformer of speech. The *Medical Press and Circular* for March 15th reports him as having, at a society meeting, "objected to the expression 'radical cure,' preferring to style it the operation for radical cure." This criticism strikes us as on

a somewhat higher plane from the purist's point of view than Mr. Owen's subsequent remarks, which are put as follows in the report: "He urged that unless the infant were well looked after it might be necessary to operate under six years of age. He himself operated as young as three." The italics are ours.

AN OVERDOSE OF PELLETIERINE.

THE *Centralblatt für die gesammte Therapie* for April cites from the *Deutsche Medizinal-Zeitung* a case reported by Cielas in which half a gramme (between seven and a half and eight grains) of pelletierine sulphate, given to an epileptic thirty-four years old to expel a tapeworm, produced death within a few hours, preceded by vertigo, vomiting, cramps and paralysis of the limbs, and coma. The occurrence leads Cielas to recommend that in the treatment of tapeworm the tannate of pelletierine be used instead of the sulphate. To the best of our information, the tannate is already the salt of pelletierine most commonly used, and we think a more pertinent suggestion would be that of prescribing a much smaller dose.

THE BICYCLE FOR PERSONS WITH HERNIA.

THE indications are that it will soon be difficult to mention an ailment whose victims, provided they are not bedridden, may not, in somebody's opinion, derive benefit from the use of the bicycle. M. Vermeulen (*Presse médicale*, April 8th) cites M. Lucas-Championnière as maintaining that persons with hernia find that bicycle-riding strengthens the abdominal wall, improves the general health, moderates the tendency to obesity, flatulence, and constipation, and is capital for muscular weakness.

HEREDITY WITHOUT COLLUSION.

THE Rev. Edward Everett Hale has lately produced a book entitled *James Russell Lowell and His Friends*. We have not seen the book itself, but in a newspaper review we find this quotation from it: "From no indulgence of his own, he was a victim of hereditary gout." As the review appeared in the *Sun*, we take it for granted that the quotation is correct, and must absolve the late Mr. Lowell from having been accessory to his unwelcome heritage.

SUPPURATIVE EPIDIDYMITIS IN TYPHOID FEVER.

SUPPURATION of the epididymis is one of the rare complications of typhoid fever. In an abstract (*Centralblatt für Chirurgie*, April 8th) of a report of a case by Strasburger (*Münchener medizinische Wochenschrift*, 1899, No. 1) we find it stated that there are only eight cases on record. In Strasburger's case, in which the inflammation began during the third week of convalescence, there was no preceding urethral catarrh. The pus contained typhoid-fever bacilli.

THE SURVIVAL OF THE PNEUMOCOCCUS OUTSIDE THE ORGANISM.

M. LEMÛRE (*Nord médical*, April 1st) recently reported to the Society of Medical Sciences of Lille some experiments which he had made with pus taken from a child four months old, who died from the disease. Ex-

amination at the time showed staphylococci and some indeterminate forms which might have been pneumococci, but cultures therefrom gave colonies of pneumococci in forty-eight hours. Three months and a half later M. Lemièrè found that the flask containing the sown pus contained fertile cultures of pneumococci, but no staphylococci. This pneumococcus was still virulent and produced death on inoculation into mice. M. Lemièrè draws attention to the importance of this fact as indicating the danger attendant upon the exposure of slowly drying pneumonic sputum.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 22, 1899:

DISEASES.	Week ending Apr. 15.		Week ending Apr. 22.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	8	4	15	7
Scarlet fever.....	227	4	217	16
Cerebro-spinal meningitis.....	0	16	0	11
Measles.....	270	12	335	16
Diphtheria.....	199	39	180	26
Croup.....	15	2	13	7
Tuberculosis.....	202	173	191	141
Small-pox.....	20	0	2	1
Chicken-pox.....	30	0	26	0

The Congress of American Physicians and Surgeons.

—At a recent meeting of the executive committee the following officers of the congress were elected: President, Dr. H. P. Bowditch, of Boston; secretary, Dr. W. H. Carmalt, of New Haven; treasurer, Dr. Newton M. Shaffer, of New York; chairman of the executive committee, Dr. Landon Carter Gray, of New York; secretary of the executive committee, Dr. W. K. Simpson, of New York. The next congress will meet in Washington in May, 1900.

The Loomis Laboratory.

—The legislature has passed a bill empowering the trustees to dispose of the property, and it has been signed by the governor.

The State Board of Health of Delaware

has established a laboratory in Newark, at the State college, for the purpose of aiding the physicians of the State in the diagnosis of typhoid fever, diphtheria, tuberculosis, and other diseases in which an examination of urine, blood, feces, stomach contents, etc., may be necessary. The aim will also be to carry on original investigations with a view of furthering the progress of sanitary science in general and bacteriology in particular. Professor Chester, State bacteriologist, has been appointed director and Dr. A. Robin bacteriologist and pathologist.

The New-Yorker medicinische Monatsschrift. Dr. A. Ripperger has become the editor, succeeding Dr. Alfred Michel.

Changes of Address.—Dr. A. C. McGuire, to No. 1851 Seventh Avenue, New York; Dr. William O'Donnell, to No. 253 East One Hundred and Twenty-third Street, New York; Dr. W. H. Proleau and Dr. Lord C. Valentine, to No. 31 West Sixty-first Street, New York.

The Death of Mr. Jabez Hogg, of London, is reported to have taken place on April 23d. He was eighty-two years old. For many years he was a prominent ophthalmologist.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, and plague were reported to the supervising surgeon-general for the week ending April 22, 1899:

Small-pox—United States.

Los Angeles, Cal.....	Mar. 25-Apr. 8	4 cases.	1 death.
Denver, Col.....	Mar. 18-Apr. 1	9 "	
Washington, D. C.....	Apr. 1-18	17 "	
Jacksonville, Fla.....	Apr. 8-15	1 case.	
Elmira, Ind.....	Apr. 8-15	2 cases.	
Louisville, Ky.....	Apr. 1-6	15 "	1 "
Louisville, Ky.....	Apr. 6-13	11 "	1 "
New Orleans, La.....	Apr. 1-8	5 "	
New Orleans, La.....	Apr. 8-15	18 "	1 "
Shreveport, La.....	Apr. 18	1 case.	Imported from Mexico.
Boston, Mass.....	Apr. 8-15	5 cases.	
Benton Township, Mich.....		Reported present.	
Kalamazoo, Mich.....	Apr. 1-15	5 cases.	
Watervliet Township, Mich.....		Reported present.	
Buffalo, N. Y.....	Apr. 20	1 case.	
Elmira, N. Y.....	Apr. 8-15	1 "	
Cincinnati, Ohio.....	Apr. 1-7	27 cases.	1 death.
Cincinnati, Ohio.....	Apr. 7-14	11 "	
Cleveland, Ohio.....	Apr. 8-15	13 "	
Johnstown, Pa.....	Apr. 8-15	1 case.	
Pittsburgh, Pa.....	Apr. 8-15	3 cases.	
Providence, R. I.....	Apr. 20	1 case.	
Alexandria, Va.....	Apr. 15	1 new case.	
Newport News, Va.....	Apr. 8-13	10 cases.	
Norfolk, Va.....	Apr. 7-12	23 "	
Portsmouth, Va.....	Apr. 7-12	18 "	1 "
Spokane, Wash.....	Apr. 1-8	2 "	

Small-pox—Foreign.

Ghent, Belgium.....	Mar. 25-Apr. 1	1 death.	
Bahia, Brazil.....	Mar. 11-18	3 cases.	1 "
Hongkong, China.....	Feb. 25-Mar. 4	2 "	1 "
Barranquilla, Colombia.....	Mar. 25-Apr. 1	2 "	
Cairo, Egypt.....	Mar. 11-18	1 "	
London, England.....	Mar. 18-25	1 case.	
Tamsui, Formosa.....	Jan. 1-31	2 cases.	
Tamsui, Formosa.....	Feb. 1-28	15 "	
Mexico, Mexico.....	Apr. 1-9	1 case.	6 deaths.

Plague.

Tamsui, Formosa.....	Jan. 1-31	56 cases.	35 deaths.
Tamsui, Formosa.....	Feb. 1-26	125 "	84 "
Tamsui, Formosa.....	Feb. 22-Mar. 8	107 "	63 "

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 8 to April 22, 1899:*

AMES, ROGER POST, Acting Assistant Surgeon, will proceed from New Orleans to Havana for duty.

AUSTIN, R. EMMER, Acting Assistant Surgeon, is relieved at Camp Wetherill, Greenville, and will proceed to Fort Sam Houston to accompany the Tenth Cavalry to Santiago.

BARRY, EDMUND, Acting Assistant Surgeon, will proceed to the Joseph Simpson General Hospital, Fort Monroe, Virginia, for duty.

BRACKETT, JOHN E., Acting Assistant Surgeon, is relieved from the hospital ship *Missouri* and will proceed from Fort Monroe, Virginia, to Washington.

CLENDENIN, PAUL, Major and Surgeon, is relieved as chief surgeon, Second Division, Second Army Corps, and will proceed to Santiago for duty.

EDGAR, BENJAMIN J., Acting Assistant Surgeon, is relieved at Washington Barracks and will proceed to Fort Monroe for duty.

GIBSON, ROBERT J., Major and Surgeon, is relieved at Fort Meade, Pennsylvania, and will proceed to San Francisco for duty.

GROFF, GEORGE G., Major and Brigade Surgeon. The order discharging him is revoked.

KIEFFER, CHARLES F., Captain and Assistant Surgeon, is relieved at Fort Meade, Pennsylvania, and will proceed to San Francisco for duty.

KOERPER, EGON A., Lieutenant-Colonel and Deputy Surgeon-General, is detailed as a member of the army retiring board appointed to meet in Omaha, Nebraska.

M'CALL, JAMES H., Acting Assistant Surgeon, will proceed to Jackson Barracks, Louisiana, for temporary duty. On his arrival, PLUMMER, GEORGE R., Acting Assistant Surgeon, will proceed to Havana for assignment to duty.

M'DILL, JOHN R., Major and Brigade Surgeon, is relieved from Columbia, Havana, and will report to the surgeon general.

M'GEE, ANITA NEWCOMB, Acting Assistant Surgeon, will proceed to Fort Monroe on official business of the medical department.

MANLY, CLARENCE J., First Lieutenant and Assistant Surgeon, is appointed acting assistant quartermaster and acting commissary on the hospital ship *Missouri*, now at Newport News, to relieve WEISER, CHARLES, Captain and Commissary.

PHILLIPS, JOHN L., Major and Chief Surgeon, United States Volunteers, is relieved with the Second Army Corps, and will proceed to Boston as attending surgeon of recruits.

REED, WALTER, Major and Surgeon, will proceed to Havana for the sanitary inspection of the camps, barracks, and hospitals in the vicinity of Puerto Principe, and to report upon the causes of the prevalence of typhoid fever among the troops at that place. Major Reed will return to Washington and make a full report of his investigations.

ROBERTS, FRANK, Acting Assistant Surgeon, is relieved at Camp Near, Port Cabanas, Havana, and will proceed to Washington.

SHAKESPEARE, EDWARD O., Major and Brigade Surgeon, United States Volunteers, will proceed to New York on business of the medical department.

STARK, ALEXANDER N., Captain and Assistant Surgeon, is relieved from command of the hospital ship *Hid* at Fort Monroe, Virginia, and assigned to command the hospital ship *Terry* at Havana.

SWIFT, EUGENE L., Captain and Assistant Surgeon, will proceed to Boston for examination of the Eighth Massachusetts Volunteers, to be mustered out.

THOMAS, HENRY D., Major and Brigade Surgeon, United States Volunteer, will proceed to Fort Sam Houston, Texas, to accompany the Tenth Cavalry to Cuba.

WELL, DAVID D., Acting Assistant Surgeon, is relieved from the hospital ship *Missouri* on arrival at

Havana, and will report to the commanding general of Cuba for duty.

WILCOX, CHARLES, Captain and Assistant Surgeon, is relieved at Fort Bliss, and will proceed to Fort Sam Houston for duty.

WILSON, WILLIAM H., Captain and Assistant Surgeon, is detailed as a member of the examining board at Fort Monroe, *vice* HARTNETT, EUGENE H., First Lieutenant and Assistant Surgeon.

WILSON, WILLIAM H., Captain and Assistant Surgeon, is detailed as a member of the examining board appointed to meet at Fort Monroe, *vice* HARTNETT, EUGENE H., First Lieutenant and Assistant Surgeon, relieved.

WINNE, CHARLES K., Major and Surgeon, is detailed as a member of the army retiring board appointed to meet in Omaha, Nebraska.

WOODSON, ROBERT S., Captain and Assistant Surgeon, will proceed to Fort Clark, Texas.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending April 22, 1899:*

DE LANCY, C. H., Assistant Surgeon. Detached from the *Amphitrite* and ordered to temporary duty at the marine recruiting rendezvous, Savannah, Georgia.

CRAWFORD, M. H., Surgeon. Ordered to duty at the naval rendezvous, Chicago.

TAYLOR, J. S., Assistant Surgeon. Detached from the recruiting rendezvous, Chicago, and ordered to the *Independence* temporarily.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending April 20, 1899:*

WHITE, J. H., Surgeon. To proceed to Savannah, Georgia, for special temporary duty. April 15, 1899.

CARRINGTON, P. M., Surgeon. Upon completion of inspection duties, to proceed to the Brunswick (Georgia) quarantine station, while *en route* to rejoin station at Washington, D. C., for special temporary duty. April 7, 1899.

COBB, J. O., Passed Assistant Surgeon. To proceed to Fort Stanton, New Mexico, for the purpose of establishing a marine hospital at that place. April 19, 1899.

WERTENBAKER, C. P., Passed Assistant Surgeon. To proceed to Newport News, Norfolk, and Portsmouth, Virginia, for special temporary duty. April 8, 1899.

NYDEGGER, J. A., Passed Assistant Surgeon. To inspect unserviceable property at Wilmington, North Carolina. April 8, 1899.

WICKES, H. W., Assistant Surgeon. Granted leave of absence for seven days. April 8, 1899.

CRIMMING, H. S., Assistant Surgeon. To proceed to Norfolk, Virginia, for special temporary duty. April 8, 1899.

MATHEWSON, H. S., Assistant Surgeon. To inspect unserviceable property at the San Francisco Quarantine Station. April 15, 1899.

VOX EZBOUR, R. H., Assistant Surgeon. To proceed to Savannah, Georgia, for special temporary duty. April 7, 1899.

McCONNELL, A. P., Acting Assistant Surgeon. Granted leave of absence for four days from April 17, 1899. April 17, 1899.

MARSH, W. H., Acting Assistant Surgeon. Granted leave of absence for five days from April 25, 1899. April 18, 1899.

DUDLEY, D. E., Sanitary Inspector. To proceed to the Tortugas Quarantine Station for special temporary duty. April 7, 1899.

LA GRANGE, J. V., Hospital Steward. To proceed to Fort Stanton, New Mexico, and report to Passed Assistant Surgeon J. O. COBB for duty and assignment to quarters. April 19, 1899.

TODT, W. C., Acting Assistant Surgeon. Granted leave of absence for five days. April 17, 1899.

Board Convened.

Board convened to meet at Philadelphia, Pennsylvania, at ten o'clock, A. M., April 18, 1899, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon H. W. AUSTIN, chairman; Assistant Surgeon M. J. WHITE, recorder.

Appointments.

HILL, E. D., of Massachusetts, appointed Acting Assistant Surgeon, United States Marine-Hospital Service, for the physical examination of keepers and surfmen in the Life-Saving Service at Plymouth, Massachusetts, and vicinity. April 15, 1899.

HOWELL, D. C., of Michigan, appointed Acting Assistant Surgeon, United States Marine-Hospital Service, for the physical examination of keepers and surfmen in the Life-Saving Service at East Tawas, Michigan, and vicinity. April 15, 1899.

Society Meetings for the Coming Week:

MONDAY, May 1st: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Improvement; Boston Medical Association (annual); St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.

TUESDAY, May 2d: Association of American Physicians (first day—New York); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Cattaraugus (annual—Salamanca), Columbia (annual—Hudson), Orange (annual), and Mercer (annual), N. Y.; Hudson, N. J., County Medical Society (Jersey City—annual); Androscoggin, Maine, County Medical Association (Lewiston); Connecticut River Valley Medical Association (Bellows Falls—Vermont); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, May 3d: Kansas Medical Society (first day—Topeka); Wisconsin State Medical Society (first day—Oshkosh); Association of American Physicians (second day); New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the

County of Richmond, N. Y. (New Brighton); Essex, Massachusetts, North District Medical Society (annual—Haverhill); Plymouth, Massachusetts, District Medical Society (annual); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, May 4th: Kansas Medical Society (second day); Wisconsin State Medical Society (second day); Association of American Physicians (third day); New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Medical Society of the County of Orleans (semiannual—Albion), N. Y.; Boston Medico-psychological Association; Ocean, N. J., County Medical Society (Tom's River); Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

FRIDAY, May 5th: Kansas Medical Society (third day); Wisconsin State Medical Society (third day); Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, May 6th: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Births, Marriages, and Deaths.

Married.

BARSTON—THOMPSON.—In Opelousas, Louisiana, on Tuesday, April 18th, Mr. Tracy Barston and Miss Fannie Thompson, daughter of Dr. William Marshall Thompson.

BONDURANT—PRINCE.—In Mobile, on Wednesday, April 19th, Dr. Eugene DuBose Bondurant and Miss Annie Laurie Prince.

BURRELL—CAYFORD.—In Skowhegan, Maine, on Monday, April 17th, Dr. Herbert Leslie Burrell, of Boston, and Miss Caroline W. Cayford.

BEXTON—SHRADY.—In New York, on Thursday, April 20th, Mr. Walter Graeme Bexton and Miss Jeanie Lockhart Shraday, daughter of Dr. John Shraday.

CLEMENS—HEYE.—In New York, on Saturday, April 23d, Dr. James B. Clemens and Miss Marie Antoinette Heye.

RICHARDSON—WOOTTON.—In New York, on Thursday, April 20th, Dr. Charles H. Richardson and Miss Mary Isabel Wootton.

SMITH—MUNGER.—In New York, on Tuesday, April 18th, Dr. Earle Terry Smith, of New Haven, and Miss Georgine Dows Munger.

Died.

CONWAY.—In New York, on Saturday, April 23d, Dr. John R. Conway.

KEMP.—In New York, on Thursday, April 20th, Dr. William M. Kemp.

MARTIN.—In London, England, on Wednesday, April 19th, Dr. John M. Martin, of Boston, in the forty-sixth year of his age.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XVI.

RIGHT TO COMPENSATION.

Right Usually Founded upon Implied Contract of Patient.—It has been observed that a patient impliedly contracts with a physician, when he engages his services or when he receives the physician's professional attention, that he will make a reasonable and proper compensation therefor. The right of the physician to his fee is probably governed in nineteen out of twenty cases by this implied contract. Occasionally, however, there is a special contract superseding the one implied by law, and, probably with still greater frequency, there are peculiar circumstances attending the case which materially affect the contract as ordinarily implied. The implied promise of payment may arise from either one of two circumstances: First, from the employment of the physician to attend the patient, and second, from the mere attendance of the physician and an acceptance of his services, even though not expressly requested.

From the fact that the mere employment of the physician creates a liability for the payment of his fee, it follows that if a physician is sent for to attend a certain patient, and upon promptly responding to the call the physician is informed that another physician is in attendance, or that the trouble is passed, or that for any other reason his services are not required, he will, nevertheless, be entitled to the ordinary and reasonable compensation for making the call.*

The mere acceptance of the services of a physician being sufficient to bind the patient to pay therefor is another sufficient reason for the rule of law heretofore observed, that the physician is entitled to compensation not only for the first visit made at the patient's express request, but also for all subsequent visits which the patient's condition requires.

Right to Compensation for Services of Student.—The physician is entitled to a fee for services rendered by students who attend upon his patients under his directions, and the fact that such students are not legally qualified to practise medicine and surgery in their own names and collect fees for such services does not affect this right.† And so, where a physician employs another physician to assist him, he is entitled to recover for the services of such assistant.‡

Right of Irregular Practitioners to Recover Fees.—One practising an irregular branch of medicine, such as Christian Science, spiritualism, or the like, if not prohibited so to do by the law of his State, is entitled to fees for such services. In the case of *Wheeler vs. Sawyer*, the defense interposed was "that the so-called 'Christian Science' is a delusion; that its principles and methods are absurd; that its professors are charlatans; that no patient can possibly be benefited by their treatment." The court said, "We think this all immaterial. We are not required here to investigate

'Christian Science.' The patient chose that treatment, and received it, and promised to pay for it. There is nothing unlawful or immoral in such a contract. Its wisdom or folly is for the parties, not the court, to determine."*

The question whether or not a physician who has not fully complied with the requirements of the law can recover his fees is treated at length in the following chapter.

Sunday Contracts Valid.—The contract of the physician being construed to be one of necessity and charity, comes within the exception provided for by the statutes, which declare all work done and contracts entered into on Sunday to be unlawful, and therefore the physician is entitled to his regular fees for medical services rendered on that day.†

Amount or Rate of Fee Collectible.—The amount of fee to which a physician is entitled is not a question of law, but is rather one of fact, and is determined by the customs of the locality and by the circumstances of the particular case. In many localities one dollar is the regular fee for making an ordinary day call, and in such localities the physician would not be entitled to collect a larger fee for an ordinary day visit without a special understanding, for customs of this sort may assume the force and effect of unwritten laws; in other localities custom allows a larger fee. It is presumed, however, that the rate of fees is based upon the condition existing in the particular locality, and that a careful examination and comparison of the rates of fees and of the conditions of their respective localities will show a wise and equitable adjustment of the question throughout the country. What constitutes a visit may also be regulated by custom. If a visit is required to be prolonged beyond a certain period, custom may establish the practice of charging extra for all time expended beyond the limit fixed, or a physician may establish such a custom for himself by generally announcing it among his patients. His right to the added compensation would at first, however, be dependent upon the announcement of his special terms to the particular patient, and this announcement would, if acted upon, be equivalent to a special contract for such increased fee. But after the custom became generally known and recognized no special notice would be required to fix the liability upon the patient.

The fees for performing operations are also subject, to a certain extent, to customs; there are, however, many operations of an unusual character which from the nature of the case can not be provided for by customs. Many operations being of a difficult character, it becomes advisable often to acquire the services of a surgeon specially skilled in that line of work, or specially qualified to perform the particular class or kind of operation. The services of such men are not, and can not be, subject to the customs prescribing the rate of fee in the particular locality in which the services happen to be rendered. Also, a physician who is called from a distance because of his special fitness, or for other reasons, may collect for such services, basing the amount of his fee upon the rate customarily charged by him and not upon the rates charged at the place where he visits the patient.

Where, however, a physician is called from a distance

* See *Barlett vs. Spickman*, 95 Mo., 126; *Whendley vs. City of Covington*, 11 Bu-b, 18.

* *Wheeler vs. Sawyer* (Me.), 15 A. Rep., 67; 6 N. Eng. Rep., 826. See, however, *N. Y. Med. Jour.*, March 11, 1899, p. 347.

† *Smith vs. Watson*, 14 Vt., 332; *Aldrich vs. Blackstone*, 128 Mass., 148. See *N. Y. Med. Jour.*, March 4, 1899, p. 314.

to see a person either on business or social matters, and while there attends him professionally, he is not entitled to the same compensation as though he were summoned to attend him professionally; in the latter case he would be entitled to a greater compensation based upon the loss or abandonment of home practice, while in the former case he would merely be entitled to a compensation for the time spent in attending the sick person professionally, and perhaps for the expenses of the trip. The allowance or disallowance of the last item would depend very much upon the circumstances of the case.*

Upon the same principle it has been held that where a physician lives at his brother's house as a member of the family, he is not entitled to compensation for uninterrupted medical attendance and services during the entire time of the brother's sickness. In this case Justice Hanna said: "The testimony shows that the claimant, while he attended his brother, the decedent, did not devote all his time and attention to his patient, but that he acted as a member of the family, sleeping and taking his meals in the house, going out and returning at his pleasure; and though, no doubt, he rendered many kind, thoughtful, and affectionate attentions to his suffering brother, yet they formed no part of his duties as a physician, and can not after the death of that brother be made the basis of pecuniary compensation. The most the claimant is entitled to is to be paid for the professional visits made, and the number of operations performed by him, at the usual rate of practising physicians." †

The supreme court of Louisiana has held that a physician's charges against an estate for services rendered to the deceased are not to be based entirely upon the physician's skill and the character of the services, but that the ability of the state to pay for such services should be considered in determining the amount of the fee. In this case the deceased had stricture of the œsophagus, probably cancerous in its nature. He could not be fed through the mouth and artificial means had to be resorted to. The purpose was for a time accomplished by inserting a flexible tube through which liquid nourishment was given him, but this means soon failed, the stricture becoming complete and rigid. The physician then resorted to the operation of gastrotomy, after which the patient survived twenty-one days, having been under the care of the physician for a period of sixty days. The physician rendered a bill of \$2,500. The supreme court, in considering the amount of the fee, said: "The physician should be paid, but the charge is disproportionate to the man's estate and condition in life. His estate is inventoried at \$8,705. The lower court allowed five hundred dollars. We increase it to one thousand dollars." ‡

Courts have, however, repeatedly held that the rate of fees chargeable by physicians is in no way affected or altered by the financial circumstances of the patient. This is undoubtedly the law as applied in suits between physician and patient, but when the claim is being enforced against the estate of a deceased patient, as in the above case, then the court may be more disposed to follow this precedent.

A recent case which may well illustrate the impossibility of laying down a fixed rule for the regulation

of professional fees in surgical cases, or cases requiring unusual or peculiar skill and ability, is that of *Heintz vs. Cooper*.* In this case, the patient had sustained a compound fracture of the leg and dislocation of the ankle joint. Both bones were broken and protruded through the flesh, and six or seven pieces of the bone were removed. The physician's services commenced July 12th and continued through until October 13th following, during which time plaintiff testified he made about two hundred visits and about seventy of these were for the purpose of dressing the wound; that five dollars to ten dollars a visit when the wound was dressed, and two dollars and fifty cents a visit for all other visits, was a reasonable charge; and that for reducing a compound fracture of the leg, two hundred and fifty dollars to five hundred dollars was a reasonable compensation. On the other hand, the professional evidence introduced by the defendant was that five hundred dollars was a reasonable compensation for all services rendered in the case. The jury returned a verdict for seven hundred and fifty dollars. Upon the appeal of this case, Justice Haynes said: "It appeared, however, that in no case in Monterey County within the knowledge of the medical witnesses had so large fees, in the aggregate, been paid in case of compound fracture, though in none of the instances mentioned was the character of the fracture or the number of visits stated; and it is now contended on behalf of appellant (the patient) that the prices so paid in those other cases in that county determine what is a reasonable compensation for plaintiff's services in this case, or, as counsel stated it, 'the usual price at the time and place of performance is the rule.' The cases cited in support of this proposition relate to ordinary services, as to which there is a reasonably uniform established rate of compensation, and not to professional services, where the skill and learning of the person, as well as the almost infinite variety in the character and circumstances of the subject upon which he devotes his services, precludes the establishment of any fixed rate of compensation which could be applied to more than a very restricted class of cases and the more common class of services."

In short, the amount of the fee which a physician and surgeon is entitled to charge is governed, in the case of ordinary and usual services, by the generally recognized customs prevailing at the time and place where the services are rendered, or, if he is called from a distance to perform such services, then by the custom prevailing in his locality. But in case of unusual or peculiar services no such general custom will rule; all of the attendant circumstances must be taken into consideration and a fair and equitable amount thereby determined upon. A more definite and certain rule than the above can not be well given.

Consultant's Fee. In case of consultation, the custom seems so well established, that the patient will pay the fee of the consultant, that an agreement between the patient and attending physician that the latter will pay the consultant's fees does not release the patient from paying such fees unless the consultant is informed of such arrangement before the services are rendered. †

Where, however, an attending physician takes another physician to a patient's home to consult, the patient that he is doing all that can be done, and the physician so called in does not do whatever for the patient, and is not, in fact, called in at the patient's

instance or request, the patient is under no obligation to pay him anything.* Nor does it necessarily follow where a patient employs two physicians, who, in fact, meet at his bedside at each call, that each meeting will rank as a consultation. In the matter of Succession of Duclos, the court said: "As to the pretension that, from the moment more than one physician is called in, and attends regularly upon a case, every visit made by every physician employed takes rank as a consultation, it can not be listened to, even supposing that the visits are made at the same hour, so that the physicians actually meet at the patient's bedside. The difference of the charge for what is technically styled a consultation, and for a simple visit, would make it ruinous to most patients and unreasonably onerous to all, to avail themselves of the lights of more than one of the faculty in time of need."†

Failure to Benefit Patient no Bar to Recovery of Compensation.—A consideration of those things which may be urged as defeating the right of the physician to compensation brings us first to the effect of the failure by the physician to benefit his patient. The contract of the physician that he is possessed of ordinary skill and knowledge, and will use due care and diligence in exercising them, does not guarantee his ability to effect a cure in all cases, nor indeed is it an assurance that his services will even be beneficial. If, therefore, the test of a successful treatment is to be considered a prerequisite to the physician's right to recover for such services, it is patent that a new requirement is interposed by the law. This, however, is not the case; it has been laid down as law that if the physician possesses ordinary knowledge and skill and uses reasonable and due care in their exercise, he does all the law requires of him; this proposition is correct, and is therefore applied as a test of the physician's right to recover regardless of the benefit or injury following his treatment. The court well stated the law in a Pennsylvania case in the following words: "The fact that a professional man does not succeed in accomplishing that for which he is employed, can not affect his right to recover for services rendered, unless actual want of skill be specifically shown."‡

Pith of Current Literature.

Dry Gangrene of the Thumb due to Carbolic Acid.—

The *Canadian Practitioner and Review* for April states that at a society meeting Dr. Peters showed a case in which the thumb was gangrenous superficially as far back as the metacarpophalangeal articulation. On cutting into it after amputation it was found that the whole of the terminal phalanx, including the bone, was completely necrotic, but the bone of the proximal phalanx had survived, as well as part of the subcutaneous tissue. The skin had become less and less deeply affected as the hand was approached, showing that the cause of the gangrene was some substance acting from without inward, and that it was not due to any vascular thrombosis or embolism, nor to any vasomotor spasm as in

Reynaud's disease. The patient gave a history of having scalded the thumb with a mixture of carbolic acid, salt, and soap, in June, 1898, and denied any contact with the acid since that date. There was very good reason, however, to discredit that history, and to believe that the poisoning was self-inflicted about ten days before the date of amputation.

A Movable Third Kidney.—Mr. Watson Cheyne, F. R. C. S. (*Lancet*, January 28th), records a case in which, on abdominal section, a well-developed kidney was found on the right side of the lower part of the spinal column just at the brim of the pelvis, having its own ureter and blood supply, and distant about from three to four inches from the right kidney, which was felt in the right loin and was apparently of normal size. The hand passed up into the left loin also grasped the left kidney, which was somewhat smaller than the right. In this case the symptoms were no doubt due to the mobility of the kidney and probably to slight pressure on, or kinking of, the ureter.

The literature on this subject appears to be meagre.

The Nature of Chronic Nephritis.—Dr. Albert G. Nicholls (*Montreal Medical Journal*, March) says that in the nephritis that occurs in a chronic disease, as in the case of the constitutional diseases, diabetes, tuberculosis, etc., we have mostly a degenerative process from toxic influences, or a mixed infection. In carcinoma we must look for secondary infection or an intestinal lesion.

The idiopathic or "cryptogenetic" cases are most likely to be of the nature of infections from the alimentary tract, a mere congestion of this tract being sufficient.

The author sums up his conclusions as follows:

1. The different forms of Bright's disease are to be regarded as various stages in the same general process, there being a unity pervading the whole pathological picture. 2. All forms of nephritis are due in the immense majority of cases to infective agents; the acute, to the usual specific germs of the primary disease, and the chronic, as a general rule, to the *Bacillus coli*, though other germs may sometimes be concerned. 3. Acute interstitial inflammation and subsequent connective-tissue hyperplasia are the keynote of the process; this is, however, preceded by parenchymatous degeneration. 4. The point of invasion by the *Bacillus coli* is the gastro-intestinal tract; those of other germs may be various. 5. The liver and mesenteric glands are the first barriers of defense; and the endothelial cells of the capillaries and the secreting tubules of the kidney have the power of ingesting bacteria, this being an attempt at inhibition and elimination.

Syrup of Rhubarb Incompatible with Ergotine.—

The *Settimana medica* for March 25th gives the *Journal de pharmacie d'Anvers* as authority for the statement that syrup of rhubarb precipitates ergotine, no matter by what process the ergotine has been prepared. This is owing to the tannin contained in the rhubarb.

A Modification of Local Anæsthesia by Means of

Cocaine and Morphine.—Ceci (*La Semaine méd.*, February 8; *Medical News*, April 8th) has used with complete success in more than a thousand operations a combination of morphine and cocaine. The morphine is injected some minutes before the cocaine so that its general effect may be felt before the injection of the latter. The dose of the morphine for an old person is

* Schrader vs. Hoover, 11 N. W. Rep., 463.

† Succession of Duclos, 11 La. Ann., 496.

‡ Toolman vs. Loewengrund, 2 W. N. C., 272.

from a third to half a grain, and only one half as much for a young person. The cocaine is dissolved in a three-per-cent. boric-acid solution, so that it shall contain one half per cent. of cocaine. Proceeding in this manner, it is not necessary to obtain complete insensibility, and the amount of cocaine required is very slight. Ceci has, therefore, never had a case of intoxication and has not found it necessary to resort to the method of Schleich, as his own procedure offers all of the advantages of the Schleich method. He has operated upon three hundred and sixty-two hernias by this method, performing the radical cure, and prefers it in most cases to a general anæsthetic.

[These doses of morphine seem to us too large for ordinary use.—Ed. N. Y. M. J.]

Let in the Sunlight.—The *Manitoba and West Canada Lancel* for March says that people who keep their houses dark for fear of the sunlight spoiling their carpets and furniture have no idea of the disease-destroying influence of sunlight and air. Recent experiments made in the Pasteur Institute have shown that bacilli exposed to the sun and air were destroyed in two hours, while those exposed to the sun, the air being excluded, were alive after fifty hours of exposure. Dr. Palermo, of Naples, made an interesting experiment with cholera bacilli. He found that while those protected from the sun killed guinea-pigs in eighteen hours, as usual, those exposed to the sun, although not killed, were rendered entirely harmless. As to the influence of sun and air on bacilli, it was ascertained that the oxygen of the air had a marked effect in assisting the sun's rays, and that the bacteria suffered more from the sun's rays if the supply of oxygen was increased than if it was diminished.

Death from Functional Nervous Disease.—At a recent meeting of the Medical Society of London Dr. Robert Maguire (*British Medical Journal*, April 1st) read a paper upon deaths from functional nervous disease, which he maintained were due to exhaustion of gray nerve matter. In death from senile decay, the condition in which there was the most equal deterioration of the somatic powers, there was nevertheless usually a predominance of failure of one particular system, generally that of the heart, since this organ had no chance of rest. But the system at fault was the highest nervous system. He described four cases bearing upon this point which occurred under his own observation. Dr. Maguire believed that this served to explain the sense of impending death, which, while of no importance in the young and those suffering from very acute disease, was a serious omen in the old and those who had more prolonged illnesses. Similarly, patients in an eastern nation would die if they made up their minds to die, while those of western nations, even though neurotic, had more reserve vitality, and their morbid fears were of less moment. Dr. Maguire said that hints on the pathology of the subject might be obtained from a paper by Dr. Waller, on the Sense of Effort, published in *Review*.

The Relation between Temperament and Character.—Del Greco (*Manicomio moderno*, II, 1898, p. 161, *Journal of Nervous and Mental Disease*, April) divides two general categories for human kind: the physical, or temperament, and psychosocial, or character. A man's inner feelings determine his temperament, his relations to his fellow men, his character. The author holds that from both points of view, man is

neuroses there are well-established variations in both temperament and character which are closely correlated to the neurosis in question; thus he would speak of an epileptic or paranoiac temperament and character. In the criminal there are changes of much the same type, so that while a criminal may not be epileptic nor be a paranoiac, yet he usually possesses a temperament and a character which approach those of the epileptic and the paranoiac.

Hæmorrhage as a Sign of Congenital Syphilis.—Gottheil (*Archives of Pediatrics*, 1898; *International Medical Magazine*, March) calls attention to the importance of bleedings in infants as symptoms of congenital lues. He points out that these may be the only mark of the disease, especially at first; but that they are almost invariably accompanied by a diminution of the coagulability of the blood similar to that of hæmophilia, and that the case usually goes on rapidly to a fatal termination. Disease of the vascular walls is one of the most frequent effects of the syphilitic poison, leading to hæmorrhagic discharges from the mouth, the bowels, the bladder, or the nose; to blood accumulations under the skin and mucosæ, or in the serous cavities and internal organs; or, finally, making the syphilitic eruption itself hæmorrhagic. The author urges the importance of remembering these facts in the treatment of infants who have hæmorrhagic discharges or a hæmorrhagic eruption, the cause of which is obscure.

Green Vision in Tabes Dorsalis.—Mr. Work Dodd (*British Medical Journal*, March 18th) recently reported to the Ophthalmological Society of the United Kingdom the case of an artist, aged thirty-two years, whose sight in 1886 was quite good; in 1891 he had diplopia, from which he recovered. His color vision remained good till 1897, and he complained of defective sight shortly before being seen in July, 1898. When first seen, V. was R. $\frac{6}{60}$, L. $\frac{6}{60}$. He had Argyll-Robertson pupils, optic atrophy, and contraction of his visual fields; his gait was ataxic, and he had occasional trouble in passing water. In September, 1898, V. was reduced to R. $\frac{6}{60}$, L. hand movements. He then saw everything a bright emerald green; it appeared to him as if there was a green veil hung before his eyes, through which he saw everything; he occasionally saw rose-pink spots through the green veil in places. The colors increased in intensity when he was tired, especially the rose pink. He had also occasional sensations of very brilliant light.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of Mar. 1, 1899.

The President, S. ALEXANDER, M. D., in the Chair.

A Combined Obstetric Case and Sterilizer.—Dr. J. CLIFTON FUGAL exhibited a new operation and

When to Operate for Appendicitis; Some Operative Methods.—Dr. ROBERT L. MCGEE read a paper with this title. (See page 380.)

Dr. A. B. JOHNSON's paper had presented many important suggestions and ideas which were

new to him. Some of the statements did not coincide with his own experience. For some time past he had been of the opinion that a surgeon was perfectly justified in advising operation in any case in which there had been one well-marked attack of appendicitis, but he had also been of the opinion that if the attack had passed away in a few days the operation in the interval presented certain advantages. He had always felt that when the operation was done during the period in which the tissues outside of the appendix contained a certain amount of septic material there was an additional risk. He had feared also to use a small incision in such cases, largely because of the danger of overlooking abscesses. He had more often regretted making too small an incision than too large a one. It had seemed to him that the "interval" operation, done by the intermuscular method of Dr. McBurney, afforded a better guarantee against ventral hernia than any other procedure. He had been afraid, however, to use that method in suppurative cases, although he was well aware that it was used by many surgeons. When working through a small incision he felt that he was much more apt to overlook abscesses in the pelvis or in other parts of the abdominal cavity. His surgical technics did not admit of his opening and cleaning out disseminated abscesses among coils of intestine while working through a small incision. The idea that the peritoneum itself could take care of these secondary abscesses without their being properly evacuated and adequate means provided for the subsequent escape of the septic fluid in the abscess cavity was entirely new to him. He did not see why the original focus of suppuration, which might possibly consist of a minute perforation in an appendix, with an abscess surrounding it, should be more dangerous to the life of an individual than an abscess of five times its size situated on the opposite side of the abdomen; the micro-organisms which had produced the one had produced the other, and he could not see why they should be more active in the one than in the other. He had, in his operations, always taken that view into account. Rather than expose the patient to the risk of absorption from such an abscess he had not infrequently made another small incision on the other side of the body in order to secure more perfect drainage. It did not seem to him that the presence of iodine in the urine necessarily meant that the patient was poisoned by iodoform; this reaction could be obtained in cases in which iodoform had been used very sparingly. He had seen a very few cases of iodoform poisoning, but did not recall one in which it had arisen from iodoform gauze in the peritoneal cavity. He quite agreed with the reader of the paper, however, that loose masses of iodoform gauze in the peritoneum were dangerous, and he believed that many fatal cases of so-called intestinal paralysis were really the result of the pressure of gauze on the intestine. For that reason he had recently limited very decidedly the quantity of gauze used in the peritoneal cavity, endeavoring to use it in one thick piece, and to place it superficially, with the idea of furnishing an avenue of escape for any accumulations. Having in view the possible danger of absorption of iodoform, he had lately used only very small quantities of iodoform gauze, and it had usually been conducted down, for instance, to the stump of a gangrenous appendix, or into the iliac fossa, where the fascia was already gangrenous. It seemed to him that the presence of the iodoform did inhibit the growth of the bacteria, or the absorption of their poisonous products. He had

used small quantities of sterilized gauze, not deeply placed, whenever possible. Iodoform gauze was used only for some special and definite purpose. Regarding cases of generalized septic peritonitis, he said that he had come to the conclusion that these were invariably fatal—certainly he had never succeeded in saving one patient, although he had employed various methods of treatment. It should be said, however, that the patients had usually come to him in an almost moribund condition, so that at the time of operation, with every possible means of stimulation beforehand, death had seemed imminent before the opening of the abdomen. He had saved a few in whom there had been a progressive peritonitis of very considerable extent—i. e., abscesses occupying the pelvis, and pus spreading along to the opposite side of the abdomen. The other day he had seen what he had supposed to be one of the evil effects of the use of a number of strings of gauze packed among the intestinal coils. It was a case in which the individual had had a rather acute attack of appendicitis, but in which no pus had been found, and the intestine had presented a fairly normal appearance at the time of operation, although distended. As a precautionary measure several strands of gauze had been packed in among the intestinal coils. Intestinal obstruction had occurred, and it had been necessary to open the wound at the end of forty-eight hours. At this time examination showed that the intestine close to the strings of gauze had become so dark in color and so evidently paralyzed that the intestine was opened and an artificial anus established. The life of the man had been saved, but only with the greatest difficulty. He was not quite prepared to agree with the reader of the paper that a person with appendicitis should be operated upon as soon as the diagnosis had been made, for the reason that he thought the patient ran less risk if operated upon in the interval, and that, if frequently visited and intelligently watched, many cases of appendicitis would subside. Many of these cases often appeared to be spontaneously subsiding when first seen, as shown by the history, together with the signs and symptoms. The "interval" operation could be done in such a way as to provide perfectly against post-operative hernia, and this he did not always feel he could do if the operation were done in the suppurative stage. He was quite willing to admit that the symptoms were not infrequently deceptive, and that some patients had died because operation had been delayed. As long as there was a certain amount of tenderness over the appendix he felt that the surgeon should stand ready to operate at any moment if the symptoms seemed to demand such a course.

Dr. LUCIUS W. HORTENKISS said that he admired Dr. Morris's position in the matter of operation following the diagnosis of acute appendicitis, for it seemed to him certainly logical. Personally, he did not have the courage of his convictions sufficiently to follow this course always. The trouble was that we did not know, in a given case, what course the disease would follow. The position taken by the reader of the paper, while radical, seemed to him thoroughly logical. With regard to the technics of operation, he said that he had himself discarded for a long time past the use of iodoform gauze, and more recently had entirely abandoned gauze packing, using instead the small drainage wicks of gauze encircled in gutta-percha tissue. He had always been of the opinion that cases of true general suppurative peritonitis—i. e., of peritonitis involving every possible

portion of the peritoneal sac—must almost necessarily be fatal. Patients with generalized peritonitis, however, did sometimes recover, but in the treatment it seemed to him that most surgeons would prefer to work through a moderately large incision, as he believed Dr. Morris himself did in this class of cases.

Dr. PARKER SYMS said that he thought Dr. Morris had been the first one to take the radical stand that when a diagnosis of appendicitis had been made, operation should be advised. He was of the opinion that this was the correct position in dealing with this subject. The most dangerous cases were the so-called fulminating ones—in other words, those in which the appendix broke down before the protecting adhesions had formed, and when the first distinct symptoms of the disease might be those which shortly preceded the fatal termination. At the very outset the symptoms might be the same as in an ordinary case of catarrhal appendicitis; the temperature might be almost normal, and the pain insignificant. Just before the occurrence of the rupture the pain might be so slight as to give one the impression that the patient was nearly well. There was a wide range of cases between these fulminating ones and the very mild ones, in which the progress was step by step, and it was easier to follow the course of the disease. In cases in which an abscess was rather slowly formed around the appendix there could be no question that during the most active stage of advancement the operation was more dangerous than a little later. During the twenty-four hours succeeding the perforation of the appendix into protecting adhesions the operation seemed to him a little more dangerous than during the second or third period of twenty-four hours, but it was impossible to say during the first twenty-four hours that some fatal complication might not arise before another period of twenty-four hours had passed by. It seemed to him, therefore, wise, in a case recognized to be a grave one, to advise operation unless there was some specially good reason for deferring operation. It was well to defer operation for a few hours after the patient had been transported some distance, as from his residence to a hospital. He could not agree with Dr. Morris in some of the points that he had made regarding the technics. The disease originated from infection of the peritoneal cavity by pus; the safety of the patient lay in the fact that the abscesses had been localized by adhesions. It therefore seemed rational to evacuate these abscesses very carefully, and in such a way that no pus should contaminate the uninvaded areas. His own practice in such cases was, after exposing the coils of intestine, to have the space between the abdominal wall and the intestine packed with sponges. In this way there was but little chance of leakage into the peritoneal cavity. He then slowly opened the abscesses, having ready a number of marine sponges to absorb the pus, drop by drop, as it escaped. The evacuation must, of course, be done slowly at first. If it was properly conducted, no pus would escape into the wound. He felt firmly convinced that the aim of the surgeon should be to avoid this discharge of pus into the peritoneal cavity; certainly his own results had been excellent, and he had always taken special care regarding this part of the technics. Where the pus was allowed to escape freely among the coils of intestine the surgeon was increasing one source of danger, while he was endeavoring to control the same danger by his operation. The use of hydrogen was useful, but should not be relied upon entirely. It had also been his rule to pack in the pus

cases. His plan was to place a well-folded piece of five-per-cent. iodoform gauze down into the seat of the abscess cavity around the appendix site. A loose packing was used around the margins where the intestine was not attached to the parietal peritoneum. In this way no healthy portion of intestine could come in contact with the contaminated portion. Many authors recommended the removal of the packing at the end of twenty-four or forty-eight hours, but he believed that it was very important that it should not be removed until the fifth day, and then only those portions which came away easily and freely. In some cases the adhesions might be sufficiently firm at the end of two or three days; in others, they would not be sufficiently strong for four or five days. As to the removal of the appendix where there was a circum-appendicular abscess, it seemed to him to depend entirely upon the situation of the abscess, or rather its accessibility. It had seemed to him unwise to tear up adhesions and run the risk of the escape of pus from a localized abscess into the general peritoneum. For this reason, in a certain proportion of cases, he made no prolonged attempt to remove the appendix after rupture had occurred. He believed that the surgeon was not warranted in feeling that he had ever cured a case of true general peritonitis. It might be possible occasionally for such a case to end in recovery, but such a termination should not be credited to any form of treatment; it was rather a resurrection from the dead.

Dr. FREDERICK HOLME WIGGIN congratulated Dr. Morris on his very successful results. In his own experience, he said, he had never yet been able to save a person with general septic peritonitis. He had tried in a number of instances the method advocated by Dr. Finney, of the Johns Hopkins Hospital—viz., taking out the abdominal contents and wiping off the coils—but this had not prevented the usual fatal termination. He would prefer in such cases to follow the technics described in the paper, using peroxide of hydrogen, followed by irrigation with saline solution. His experience regarding gauze in the abdominal cavity had corresponded exactly with that of Dr. Morris, and he had accordingly long since discarded it.

Dr. R. J. WILSON said that the reader of the paper had mentioned a class of cases characterized by a lymph liquefaction, and he would like to ask whether cultures had been made in these cases, and if so, whether he had found that this lymph liquefaction had always been due to one micro-organism. This might have an important bearing on the question of exact diagnosis, as well as on the post-operative treatment. For if the streptococcus was found in pure culture in such a case, the patient might derive considerable benefit from the use of anti-streptococcus serum, or at least give evidence as to its value.

Dr. JOHNSON explained that he did not make, even in these severe cases, an incision into the peritoneum more than three inches in length, although the skin incision might, in some instances, be twice as long.

Dr. MORRIS said, regarding removal of pus collections from the peritoneal cavity in cases of wide infection, that he had apparently been commonly misunderstood, he had had in mind the case of purulent peritonitis characterized by a quantity of septated, thin, greenish fecal matter, spread over various parts of the peritoneum in the form of collections. In such a case it was his practice to remove the chief toxin by suction of fluid, and trust to leucocytosis, which was usually present, to take

care of the septic lymph or pus still remaining on the peritoneal surface, instead of wiping or flushing it off. He used the inch-and-a-half incision in most of his "interval" cases, and many of the acute infective cases, but he often used an incision three inches in length in the severe suppurative cases. He cared nothing about rules regarding the length of incision, but had fixed certain lengths in order to attract the attention of surgeons who were making unnecessarily severe surgery of their appendix work. He had stood under fire for this, but his object had finally been accomplished. In the case of widespread septic infection, the incision he used was usually three inches long, although in several instances he had made it even longer. Regarding interval operations, he said that if patients all reached the interval there would be no occasion to operate early to save life. He had tried this plan at one time a good deal, but had met with some surprises in the form of pyelophlebitis and rupture of the appendix in apparently mild cases. He had then taken a firm stand, and had adopted the rule, against his own inclinations, that operation should be the rule as soon as the diagnosis had been made. The very painstaking practice of Dr. Syme was one which appealed to most surgeons, but he objected to it on the ground that he believed leucocytosis could do better than the surgeon in managing pus which had escaped. The leucocytosis was present, and the multinuclear leucocytes were thickly massed in the peritoneum in these septic cases. As a result of prolonged observation he had adopted the plan of paying no attention to this escape of pus, and did not see any peritonitis or septicæmia following this apparently careless practice. The position was a radical one, but was based on extensive experience, and could be relied upon if the after-treatment was proper. Of course, it would not do to give the patient morphine, but if hygroscopic salts were injected into the intestine and the great lymph sac was given an opportunity, with the help of the osmosis thus induced, to dispose of these toxins, the surgeon could safely neglect the escape of pus, and could save much precious time in operating. It was well from time to time, while operating, to inject peroxide of hydrogen, followed by salt solution, as each abscess cavity was opened. A number of surgeons in this city had told him that they were "almost persuaded" on this point, but so far they had feared to adopt the practice. Dr. Clark, of the Johns Hopkins Hospital, had shown by his statistics that he had been able to pursue, with safety, a still more radical method, which involved the closure of the abdominal cavity in cases in which almost every surgeon would feel it must be drained. Finney's method of evisceration was one which he was at present especially trying to combat, and he was very sorry to see that it was gaining ground in some places. This free manipulation of the intestine was something that a well man could hardly stand, then why adopt such a murderous and unnecessary method for a patient who was desperately ill? He had had many cultures made by several bacteriologists from his appendicitis cases, and had kept records of the results. According to his recollection, it might be stated, in a general way, that where the lymph had been liquefied, the colon bacillus had been almost always present in pure culture.

Surgical Histories in our Hospitals, with Presentation of a Series of History Blanks. Dr. A. B. JOHNSON presented a communication on this topic.

Dr. ALEXANDER LAMBERT said that the reader of

the paper deserved the thanks of the society for calling attention to the value of such data, and for making his hearers realize their lost opportunities in the past.

Dr. J. CLIFTON EDGAR said that the most valuable part of these forms seemed to him to be the suggestions contained in the printed blanks regarding the way in which the clinical histories should be recorded. For the last nine or ten years he had been in the habit, in the maternity hospitals, of putting in parentheses certain suggestions as to the data which he specially desired to have recorded. In a vast subject like surgery, of course, such a plan would not suffice, and the idea of Dr. Johnson of having all the suggestions on one sheet for each region seemed to him especially novel and important.

Dr. J. H. WOODWARD said that this scheme was worthy of much commendation, but inasmuch as both the internes and the attending surgeons of our hospitals were overworked, it would seem well to secure the appointment to each hospital division of a person whose sole duty it should be to take charge of the histories in that division.

Miscellany.

An Undefended Suit for Malpractice.—On April 12th there appeared in the newspapers the announcement that Dr. Thomas H. Manley, a well-known surgeon, had been sued by a woman for two thousand dollars for alleged malpractice in the resection of a joint of the thumb, and that no defense had been made. It appears that a complaint had been served on Dr. Manley early in February in connection with this case. This he answered himself by a communication, and he thought nothing further of it until he was startled by the above-mentioned announcement. A motion has now been made to reopen the case, and in due time a proper defense will be made in the courts. This case is of unusual interest to the medical profession, inasmuch as it was that of a charity patient and, further, that it shows the importance of always referring communications relative to alleged malpractice to a competent legal adviser.

Alcoholism in Children.—At a meeting of the New York Neurological Society held on April 4th Dr. George W. Jacoby presented a little boy, four years and a half old, exhibiting symptoms which in the adult would at once lead to a diagnosis of alcoholic paralysis. In spite of the tender age of the patient this case was indeed one of alcoholic paralysis. When the child was first seen, on February 20th, it was stated that he had been well up to four weeks previously, at which time he had had severe colic without vomiting or constipation. Then the left knee joint had become swollen. Eight days previously he had been noticed to be unsteady in walking. It was found that the boy had received from a half to a full tumblerful of beer daily ever since the age of six months. Examination revealed extensor paralysis of the hands and legs, with a reaction of degeneration in all the muscles. The extensors of the thighs were unaffected, and there was no sensory disturbance. The speaker quoted some recent statistics regarding the habitual use of alcohol in a large German city. The municipal authorities had undertaken an

investigation among the school children, and had found that, of a hundred children, sixteen drank no milk. Twenty-five per cent. of the children had never tasted brandy, but had habitually drunk beer or wine. Eight per cent. had received their daily portion of brandy, "to make them strong." He thought there was an almost equally large percentage of children among the German and Irish population here who were habitually given alcoholic drinks. This case, he said, emphasized the cumulative effect of small doses of a poison long continued.

Dr. William M. Leszynsky said that eight or nine years ago he had reported a typical case of multiple neuritis occurring in a child, about six years of age, who had been given beer and whisky by its parents, in order to make it strong. He agreed thoroughly with Dr. Jacoby regarding the prevalence of this vicious habit in this country.

Dr. Joseph Collins said that he had had two such cases under observation within the last two years. One of the patients, a child of seven years, was now passing through the second attack. This child had been in the habit of drinking beer. He had not completely recovered his muscular power when the second attack came on. The speaker had been impressed with a phenomenon presented by all the cases that he had seen, and it was present in the case just exhibited, namely, the remarkable pallor of the cutaneous surface as compared with the redness of the mucous membranes. In this connection, he remarked, it was interesting to note that Hughlings Jackson had recently recorded himself again in favor of treating chorea entirely by the use of port wine.

The president, Dr. Frederick Peterson, remarked that it was very unusual for an alcoholic neuritis to exist without sensory symptoms.

Dr. Jacoby said that there was intense tenderness over the nerve trunks in his case, but no general hyperæsthesia of the skin.

Specimens from a Case of Erythromelalgia.—At the same meeting Dr. B. Sachs and Dr. A. Wiener gave this demonstration. Dr. Sachs said that this disease had been carefully studied in the past six or seven years. The only autopsy on record was in a case that had been under the care of Auerbach, and it was associated with tabes. There were changes found in the upper lumbar and sacral roots, but it was not shown that the erythromelalgia was dependent upon central disease. Mitchell and Spiller had recently observed a case in which it had seemed to them that the nerves were more involved than the blood-vessels. The specimens now shown had been taken from a man, thirty-six years of age, who had first been seen in 1898. At that time, when the part was pendulous a few minutes, there was a violet color of the foot and ankle, associated with severe pain and tenderness. A few months later a gangrenous ulcer formed on the dorsum of the foot. There was marked atrophy of the anterior tibial group of muscles. Owing to the rapid spread of the gangrene, it had been considered necessary to amputate through the thigh. According to Weir Mitchell, there was no gangrene in cases of erythromelalgia, and the disease was asymmetrical, but in this case the appearance had been typical before the occurrence of gangrene, and, moreover, slight gangrene had been reported by others. Marked arterial changes were found in this case, particularly in the larger branches of the popliteal artery. This in itself

seemed to be a sufficient justification for Dr. Gerster's opinion that the amputation should be done above the knee. The symptoms seemed to be explained by obliterating endarteritis. The changes in the nerves were so slight that Dr. Sachs looked upon them as secondary. It was interesting to note in this connection that there were at the Montefiore Home several cases of cardiac disease and marked arterial sclerosis presenting the principal symptoms of erythromelalgia. There was an interesting analogy between erythromelalgia and Erb's description of intermittent claudication.

Dr. Wiener said that specimens of nerve, skin, muscle, and connective tissue had been given to him for examination, and in not a single one were the arteries normal. Only in the distal portions of the peripheral nerves could any distinct changes be found, and they were rather degenerative than inflammatory. In all the specimens a very prominent feature was the enormous quantity of connective tissue. He had not been able to find a single case on record in which arterial changes had not been found, whereas cases had been reported in which there had been no changes in the nerves.

Dr. Ira Van Gieson said that in this case the vessels were affected to a somewhat greater extent than in the Mitchell-Spiller cases. The specimens showed plainly the predominance of the arterial changes.

Dr. C. L. Dana said that this case differed essentially from the typical ones described by Weir Mitchell in the occurrence of gangrene, and hence it was possible that the histological appearances were not exactly those found in the classical cases of erythromelalgia. Two cases of erythromelalgia were cited in which the urine had contained sugar, and the patients had improved greatly under appropriate dietetic treatment. This seemed to suggest that there might be an underlying diabetic or gouty state leading to neuritis or disease of the blood-vessels.

Dr. William H. Thomson spoke of cases of pseudo-erythromelalgia occurring in exophthalmic goitre and in allied cases characterized by persistent tachycardia. He had seen at least ten, and felt sure that when severe they might be very readily confounded with true erythromelalgia.

Dr. Leszynsky remarked that two years ago he had seen a case of acromegaly in which erythromelalgia had attacked the upper extremities.

Dr. Stieglitz spoke of a case of typical erythromelalgia which he had seen about two years ago in a drug clerk. After a few months there had developed attacks of local asphyxia in the toes, associated with severe pain. Under rest in bed and the use of the iodides the improvement had been decided. Aside from the features mentioned there had been present all the classical symptoms described by Weir Mitchell; yet, if the case had been allowed to go on unchecked, he was confident, gangrene would have developed.

Dr. Sachs insisted that the case had been a typical erythromelalgia for several months, and that the gangrene had developed at a very late stage. The fact that it occurred in a man of thirty-five years, apparently healthy in every other way, was very interesting. The man had recovered very satisfactorily from the amputation, and the pain had entirely disappeared.

Temporary (Exhaustive) Paralysis in Epilepsy.—

At the same meeting Dr. L. Pierce Clark, who had prepared a paper on this subject, presented it only in ab-

stract, owing to the lateness of the hour. An analysis of the cases reported in his paper was as follows: Cases of local exhaustion with general seizures, six; cases of paralysis at the beginning and becoming to a certain extent permanent, two; cases of exhaustion paralysis in infantile cerebral palsy cases, five; cases of exhaustion paralysis associated independently with cerebral palsy cases, but on the opposite side to that of the organic lesion, one; cases of exhaustion manifest in aphasia only, two. His conclusions were that the theory of exhaustion paralysis had been conclusively proved by physiological experiment, and that exhaustion paralysis, generally limited to the parts participating in the spasm, was confined to those parts most convulsed in general seizures. There might be exceptions to this general rule. The transient paralyses might, after a time, become permanent hemiplegias. Temporary exhaustion paralysis was essentially exhaustion of cerebral centres, and the frequency or severity of the muscular spasm was not a fair index of the amount of exhaustion of these centres. A careful study of exhaustion phenomena suggested that epilepsy was clearly allied to paralytic states, due allowance being made for the fact that the epileptic brain did not possess the normal capacity. The great frequency of epilepsy as a symptom following the track of most cerebral lesions of a transient nature tended to substantiate the clinical hypothesis of the close association of epilepsy and paralysis. Minute disseminated patches of sclerosis in different areas of the epileptic brain had been repeatedly demonstrated by various observers, and this also helped the hypothesis very strikingly. In not a few instances he had produced apparent epileptic seizures by massage.

Dr. Dana said that the photographs presented in connection with this paper gave a more graphic representation of the epileptic convulsion than any others he had seen. They should prove very helpful to teachers. He thought that when neurologists were able to make a closer study of the clinical phenomena of epileptic seizures they would be in a better position to localize the disorder.

Dr. Sachs expressed the hope that the paper would be presented in full at a future meeting.

Dr. Ira Van Gieson said that the theories of epilepsy did not seem thoroughly satisfactory, and one of the advantages of a place like the Craig Colony was the opportunity afforded for close and prolonged study. He predicted that in these cases there would be found evidence of an abnormal expenditure of energy in the cortical motor cells. In one case which he had studied, that of a patient in the City Hospital, who had had sixty seizures in one day, there had existed some unmistakable evidences in the ganglion cells of the expenditure of energy. He thought the metaplasia granules were the hitherto unrecognized evidence of this expenditure. In inveterate cases of epilepsy these granules would be found in the interior of the nerve cells and elsewhere.

The president said he had seen two or three cases of hemiplegia coming on during epileptic attacks, and it had been permanent.

Dr. Clark said that he had seen about forty cases of exhaustion paralysis, and the duration of the paralysis had varied from forty seconds to two or three weeks.

A Bad Bite.—The *Bristol Medico-chirurgical Journal* for March tells us that the house surgeon of a London hospital was attending to the injuries of a woman

whose arm had been severely bitten. As he was examining the wound he said: "What sort of animal bit you? This is too small for a horse's bite, and too large for that of a dog." "Oh, sir," replied the patient, "it wasn't an animal. It was another lady."

A Synopsis of Medico-sanitary Legislation passed in Illinois, by the Forty-first General Assembly, which adjourned on April 14, 1899.—1. An act to establish a State colony for epileptics, the object of which is to secure humane, curative, and scientific treatment and care of epileptics.

2. An act to provide for the appointment of a State food commissioner and to define his duties and fix his compensation, and to prohibit and prevent adulteration, fraud, and deception in the manufacture and sale of articles of food. Under this act it will be the duty of the commissioner to enforce all laws that now exist or that may hereafter be enacted in the State regarding the production, manufacture, or sale of dairy products or the adulteration of any article of food, and, personally or by his assistants, to inspect any article of food made or offered for sale within the State which he may, through himself or his assistants, suspect or have reason to believe to be impure, unhealthful, adulterated, or counterfeited, and to prosecute or cause to be prosecuted any person or persons, firm, or firms, corporation, or corporations engaged in the manufacture or sale of any adulterated or counterfeited article or articles of food which are contrary to the laws of the State.

3. An act giving the State board of health supervision of all lodging houses in cities of one hundred thousand inhabitants or more. Under the provisions of this measure it will be unlawful for more than six persons to occupy the same room for sleeping purposes at the same time in any such lodging house, and no room in such lodging house shall be occupied for sleeping purposes which does not contain four hundred cubic feet or more of space for each one of the persons sleeping therein at the same time. Any person or persons violating any of the provisions of this section will be adjudged guilty of a misdemeanor and be liable to a penalty not exceeding one hundred dollars. Any landlord, keeper, manager, or clerk of any lodging house who willfully or knowingly aids, counsels, advises, or permits any person to do any act in this section constituted an offense will be deemed guilty of a misdemeanor and will be liable to a penalty not exceeding one hundred dollars and not less than twenty-five dollars.

4. An act to amend "an act concerning corporations," which provides that the attorney-general may file a bill in chancery, in the name of the people of the State, against any corporation authorized to confer degrees, diplomas, or other certificate or certificates of qualification in the science of medicine, pharmacy, or dentistry, which conducts a fraudulent business or abuses or misuses or violates the terms of its charter, in any court having jurisdiction of the corporation and subject matter of such bill, for an injunction to restrain said corporation from conducting its business fraudulently or abusing, misusing, or violating the terms of its charter, and also for the dissolution of said corporation, and thereupon it will be the duty of the court in which said bill is filed to grant such injunction and to hear and determine the same as in other cases in chancery. The enforcement of this law will summarily put an end to the operations of the "diploma mills" which have disgraced the State for many years.

5. An act to regulate the practice of medicine in the State and to repeal all previous laws. This measure, which if signed by the governor goes into effect July 1, 1899, provides for the examination and licensing of persons who desire to practise medicine and surgery in all their branches, for those who desire to practise midwifery, and for those who desire to practise any other system of treating human ailments who do not use medicines internally or externally and who do not practise operative surgery.

Applications from candidates who desire to practise medicine and surgery in all their branches shall be accompanied by proof that the applicant is a graduate of a medical college in good standing, as may be determined by the board, provided that graduates of legally chartered medical colleges in Illinois in good standing, as may be determined by the board, may be granted certificates without an examination.

Examinations may be made in whole or in part in writing by the board, and shall be of a character sufficiently strict to test the qualifications of the candidate as a practitioner. The examination of those who desire to practise medicine and surgery in all their branches shall embrace those general subjects and topics a knowledge of which is commonly and generally required of candidates for the degree of doctor of medicine by reputable medical colleges in the United States. The examination of those who desire to practise midwifery shall be of such a character as to determine the qualification of the applicant to practise midwifery. The examination of those who desire to practise any other system or science of treating human ailments shall be of a character sufficiently strict to test their qualifications as practitioners, provided that those who are authorized to practise other systems can not use medicine internally or externally, or perform surgical operations, and that only those who are authorized to practise medicine and surgery in all their branches shall call or advertise themselves as physicians, or doctors; provided, further, that those who are authorized to practise midwifery shall not attend other cases than those of labor.

The fees for examination and for a certificate shall be as follows: Ten dollars for examination in medicine and surgery and five dollars for a certificate if issued; five dollars for an examination in midwifery and three dollars for a certificate if issued; for all practitioners, ten dollars for an examination and five dollars for a certificate if issued.

The State board of health may refuse to issue the certificate provided for in this act to individuals who have been convicted of the practice of criminal abortion or who have by false or fraudulent representation obtained or sought to obtain practice in their profession, or by false or fraudulent representation of their profession have obtained or sought to obtain money or any other thing of value, or who advertise under names other than their own, or for any other unprofessional or dishonorable conduct, and the board may revoke such certificates for like causes.

Any person shall be regarded as practising medicine, within the meaning of this act, who shall treat or profess to treat or operate or prescribe for any physical ailment or any physical injury to or deformity of another. This section does not apply to any person who ministers to or treats the sick or suffering by mental or spiritual means.

The examination of those "who desire to practise any other system or science of treating human ailments,"

who are not permitted to call or advertise themselves as physicians, or doctors, or to use medicine or perform surgical operations, will probably be in the following branches: Anatomy, physiology, chemistry, histology, pathology, bacteriology, and hygiene.

A bill to regulate the practice of "osteopathy" in the State passed the senate, but died in the house. This bill provided that the State board of health should issue certificates of qualification to persons presenting diplomas from legally chartered "osteopathic" schools, said certificates to be conclusive as to the right of the lawful holders to practise "osteopathy" in the State. The bill provided, further, that the system, method, and science of treating diseases of the body commonly known as osteopathy was declared not to be the practice of medicine or surgery. It will be remembered that an "osteopathic" bill passed both branches of the legislature in 1897, but was vetoed by Governor Tanner.

The Small-pox Situation in New Orleans is rapidly improving. At present only thirty-eight patients with the disease remain in the hospital. The total number of cases up to the date of our correspondent's letter is one hundred and seventy-nine. Only seven white people have contracted the disease. The death-rate has been unusually low, only three having died. All the subjects of the disease in the city at present are confined in the small-pox hospital.

The Food, etc., of the Troops in the Philippines.—James Creelman, the war correspondent whose experience includes the Chinese-Japanese and Turko-Grecian wars, writes thus from Manila to the *New York Journal*: "All sorts of wild rumors about corruption in the customs departments and about excesses by our troops have been lying about in the English press of Asia. I have investigated these matters, with the assistance of experienced and impartial men, and I find the stories absolutely false. Whatever faults General Otis may have, he has certainly proved himself to be honest and painstaking and capable of preventing malfeasance or corruption on the part of his subordinates. The quartermaster's department, under Colonel Pope, and the commissary department, under Colonel Brainerd, are nearly perfect. The men are well clothed and well quartered, and I have eaten better food in the trenches than I got in the hotel at Manila. The beef fed to the soldiers in the firing line from the refrigerator ships is as good as one can find in the average New York restaurants. The discipline of the troops is equal to that of any army in the world. It is astonishing to find volunteer regiments made up of men accustomed to the free individual life of the Western States rivaling the regular army in unvarying obedience and order. The regular officers never weary of praising the volunteers for their courage and steadiness on the fighting line. I have seen a good many armies in the field, but I have never seen such a perfectly controlled, well nourished army as this."—*Army and Navy Journal*.

False "Aids" in Botany. In the department of Botanical Notes, *Science* for April 14th says:

"This is the time of the year when the country is flooded with circulars describing 'all sorts of aids' for use in teaching or studying botany. It must be that these worthless things are bought by ignorant teachers or school boards, for otherwise they would not be advertised so freely. We have before us one of the old-style *Pontederiac* sheets, published by E. R.

Good, of Tiffin, Ohio, which proves that in some portions of our country the botanical world is supposed to have remained absolutely at rest for the past twenty-five or thirty years. As a leaf from quite ancient history in botany one of these sheets is interesting, but as an aid in modern botany it is simply ridiculous.

"From J. M. Olecott, of Chicago, we have another reminder of the past in the form of a perforated sheet of paper called *A System of Plant Study*, which we are told is a sample of the sheets which make up a book 'containing space for mounting and fully describing fifty-one botanical specimens,' and in addition 'full directions for collecting, pressing, mounting, photographing, analyzing, and preserving plant forms and specimens.' Of course, no botanist will have anything to do with such trash, but for the non-botanical it may be well to say that this is *not* the way that botanists make herbaria and describe plants. The pupil who is so unfortunate as to use such an 'aid' will have to unlearn practically everything he learns from it.

"By all odds the worst thing which has come to our attention recently is the *Teacher's Botanical Aid*, sent out by the Western Publishing House, of Chicago, and consisting of twenty-eight charts, about two feet by three, on which are rough copies of many of the illustrations found in the older text-books of botany. The copying has been done by careless or incompetent hands, so that, in spite of the author's statement that they 'will prove a direct aid in teaching drawing,' we are compelled to say that they are not only inaccurate botanically, but quite shocking from the artistic standpoint. The author intends these charts to be used in nature study, so that we are to have our children's time taken up by 'reciting' from these drawings under the impression that they are studying nature. The teachers of nature study who know nature, and 'who have depended for years upon their own resources' (to quote the author's words), will not think of putting these charts between the pupil and nature, but we fear that the unprepared and uninformed may be induced to use them. If the charts were accurately drawn they would be of doubtful value in nature study, but with all their glaring inaccuracies they are worse than useless."

The Dispensary Bill.—The profession of New York State is to be congratulated on the successful result of the long struggle for the enactment of a law which may reasonably be expected to regulate the dispensary abuse, and confine these institutions to their legitimate field of activity—i.e., providing medical aid for the worthy poor. The battle before the legislature between might and right has been a long one, and several medical societies have done yeoman service for this cause, but conspicuous among them, and especially during the closing days of the present campaign, has been the New York State Medical Association, whose committee on legislation, through its chairman, Dr. E. Eliot Harris, has labored in season and out of season to secure the passage of this bill. The successful issue should be an object lesson to the medical profession as to the possibilities of harmonious and united action.

The True Catholicity of Medicine.—The *Western Medical Review* for April—which, by the way, pays us the compliment in the same issue of appropriating *verbatim*, without acknowledgment, the leading article on the Production of Sex at Will from our issue of March 18th—quotes from the *British Medical Journal* a pas-

sage from a story of M. Paul Bourget published in the *Revue des Deux Mondes* for January 15th. We do not remember to have seen anywhere so clearly expressed a statement of the splendid independence of medicine amid the confused warring and jangle of creeds, philosophies, politics.

"What has decided me to take up medicine, strange as it may seem to you, is the need of certitude. My personal tastes would have led me to something more abstract. I should have entered the *Ecole normale* to work at metaphysics had I not read Kant and also Taine's *Intelligence*. It seemed to me that the object of philosophical studies is too doubtful. My mind is, as it were, unhungry and athirst for something positive, indisputable. The natural sciences supply this. I therefore turned toward them; then I reflected. I don't know your state of mind in regard to moral convictions. As for me, my position is that of absolute agnosticism. I am of the opinion that we can not know of certain knowledge whether, to take the simplest formula, there is a God; or, if there is not, whether there is any good or evil, or not; merit or demerit, or not; another life, or not. Nevertheless, one must act. I at least feel the necessity of action, especially since I saw war. I have the impression that I should have on a ship in danger in a storm. It is a shame to take no part in the work, if one is able to do so. I recalled to myself the reasoning of Pascal—you remember, don't you?—about the bet. I said to myself, Which among the natural sciences is the branch which lends itself to a practical use such as can be applied in all hypotheses? It seemed to me that medicine, understood in a somewhat high sense, answered this requirement. In fact, examine one solution and the other. Suppose all the spiritualist theories, nay more, all the Christian theories, to be demonstrated. What is one's duty? To relieve the being who suffers. The doctor does that. Suppose all the opposite theories to be demonstrated, to what is morality reduced? To an instinct which must be recognized and satisfied like all instincts, and which consists in the need of associating ourselves with others, of helping our fellow men, and of being helped by them against Nature, which is our enemy. Who accomplishes this task better than the doctor? He is the altruist *par excellence*. He is right, whatever be the metaphysical postulate which we accept. And this is so true that since the day when I first registered myself as a student and entered the door of the hospital I have felt a kind of calm to which I was before a stranger. It has been borne in upon me that intellectually and morally I have—how shall I say?—had my feet on the ground, that I was walking on something solid. In short, I was no longer in doubt."

Sulphur Fumes and Grippe.—In our issue for March 18th we quoted from the *Georgia Journal of Medicine and Surgery* for February a paragraph recommending the use of fumes from burning sulphur in grippe. The *Southern Clinic* for April reproduces our paragraph and adds this editorial comment:

"Now we would not advise the promiscuous burning of sulphur by patients in their rooms unless there is an able-bodied man on hand to drag them out about the time asphyxiation, strangulation, etc., commences, which is likely to be the case with the average sulphur burner."

The exception seems to us well taken, at any rate so far as the qualifying adjective "promiscuous" is concerned.

Original Communications.

REPORT OF A CASE OF
REMOVAL OF THE GASSERIAN GANGLION
WITH THE SECOND AND THIRD DIVISIONS
OF THE FIFTH NERVE,
HARTLEY-KRAUSE OPERATION.*

By JOHN F. ERDMANN, M.D.,

CLINICAL PROFESSOR OF SURGERY
IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE,
ATTENDING SURGEON TO GOVERNOR AND ST. MARK'S HOSPITALS.

THERE are few sufferers from persistent neuralgia of the fifth nerve who sooner or later are not willing to undergo operation after operation for relief of this pain, and even finally subject themselves to the most serious operations, knowing full well that the outcome may be death.

It was one of this class of patients whom it was my fortune, through the kindness of Dr. McIntosh and Dr. Senn, of South Carolina, to see last August. No better history of the case can be given than a copy of portions of the letter Dr. McIntosh sent with the patient:

"Mr. D. P. is fifty-three years old, a farmer living in the country, and leading an active, hard-working, out-of-door life; strong constitution, good family history, no specific history, and is well in every way except his trigeminal neuralgia. For the past three or four years Mr. P. has been a terrible sufferer from this disease, involving, as it does, all three branches of the fifth nerve.

"During the three or four years he has had medicinal all the usual and unusual remedies—has tried electricity (the constant galvanic current) and at times on his own responsibility has used proprietary remedies very extensively, but nothing has given him anything but partial and temporary relief.

"Last December (1897) his suffering was the worst in the skin and muscles of the left side of his scalp and upper face around the left eye, and I cut down upon and excised portions of the supraorbital, supratrochlear, and infraorbital nerves. This gave him considerable temporary relief, lasting three or four months.

"Lately the chief suffering has apparently been with the lingual and ophthalmic branches and, to a certain extent, with the pharyngeal branches. The pain has been so great that for the past ten days he has been totally unable to eat any solid food, and even at times unable to talk. The slightest movement of the tongue would start up a spasm of pain which would shoot back and seem to centre in the left eyeball. He has also had a good deal of pain in the region of the distribution of the auriculo-temporal branch and also of the small occipital and great auricular branches of the cervical plexus. He sent for me in consultation last Sunday, begging me to do an excision of his left eye and cut these painful branches. I told him this would give him only temporary relief, and again urged him, as I had for two years, to have an excision of the Gasserian ganglion done. He finally consented to have this done, and I have referred him to you."

In a parting clause Dr. McIntosh states: "It is only proper to mention that the patient's right eye (the one not involved in this neuralgia) is somewhat defective, having been injured when he was a child. Finally, I have told the patient the possible dangers of the operation, and I think he is fully prepared to undergo them."

I saw the patient on August 4th, about 2 p.m., when, in addition to the foregoing history, these facts were obtained: He had just finished a very fatiguing journey of two days' duration, and, owing to his pain, was unable to obtain any sleep, except by the use of anodynes, and could not take any nourishment, except the very smallest quantity of fluids, as efforts at swallowing caused him agonizing spasms of pain in the left side of the neck, which would extend up the face and centre about the left eye. He did not care to speak for the same reasons. His physician, Dr. Senn, who accompanied him, said that this condition had prevailed for more than ten days, and that it was a usual thing for him to have such attacks, but not so intense. Owing to the agony of the patient, he was immediately prepared for operation for the following morning, Friday. During the shaving of the scalp tears were constantly running down his face, nevertheless he motioned to continue the job and finish it as quickly as possible. A thin green-soap poultice was applied, with orders to remove it and scrub the head and place on a bichloride dressing during that evening. The following morning chloroform was given before the dressing was removed, and it was then found that the scalp was covered with numerous pustules, evidently due to too assiduous attentions in antisepsis. The scalp was washed off and a dry sterile covering placed over it and the patient put in bed. Upon recovering from the anæsthetic his pain was not improved. It was found on the second day following—i. e., August 7th—that the pustules had dried entirely and the operation was then undertaken.

Dr. Louis McLane Tiffany, of Baltimore, says: "The anæsthetic agent in all my cases has been chloroform; the age of the patient, but especially the desire to avoid congestion of the face and head, so often seen with ether, has induced me to choose this anæsthetic." Acting upon the above suggestion, chloroform was given the patient, with a most happy result. No congestion of the face or meninges was observed.

The usual steps of the Hartley-Krause operation were followed throughout. Hemorrhage at the time of the raising of the flap was profuse—in fact, so sudden and profuse that one of the surgeons present suggested compressing the carotid; but the color being dark, I immediately packed the wound with gauze, pushing the tampon well in between the dura and base. Upon removing the tampon in about three or five minutes, hemorrhage no longer occurred. It was also observed that a small nick of the dura had occurred, a few drops of free and profuse flow of cerebro-spinal fluid. This, fortunately, was an accident of no moment, as it was our intention to nick the dura, thereby allowing just such an evacuation to take place, so as to give work to do in the exposed region. The degree of ease with which the brain and dura could be retracted after the evacuation of this fluid was surprising. No effort was made to suture the nick. As the dura was raised from the base, hemorrhage proved a delay in the time occupied, as it was very free and packing was necessary every few minutes. Still,

* Read before the Society of Alumni of Bellevue Hospital, February 1, 1899.

• See *Annals of Surgery*, Vol. XXV, p. 416.

it was thought that the operation could be done in one sitting, although the duration might be unusual (the actual time was an hour and three quarters). The exposure of the second and third branches was exceptionally easy, but difficulty was found in exposing the ganglion, owing to the rather firm adhesion of the dura to the petrous bone. The nerves were cut, the distal ends pushed through their respective foramina, while the proximal ends were seized with a forceps, so that traction could be made in the direction of the ganglion. The ganglion was finally exposed, and, in attempting to remove only the portion connected with the second and third divisions, all apparently was removed, and even considerable of the nerve trunk proximal to the ganglion.

In breaking off the bone flap it became detached from its periosteum and was removed. The muscle and periosteum were sutured with a deep row of catgut, the skin superficially, and a small drain was put in for thirty-six hours. For thirty-six hours a considerable amount of oozing of cerebro-spinal fluid took place. This had entirely ceased at the end of forty-eight hours. The patient, upon coming out of his anaesthesia, refused to remain in bed, but walked about his room and kept up a constant fire of questions and stories, saying no one could keep him quiet, as he had not talked on account of pain for some days; and remarked, "Now I am going to make up for it."

His temperature and pulse were interesting, to say the least, being normal upon the date of admission and previous to date of operation. Four hours after operation the temperature was 100.4° F.; pulse, 96. The patient said he had the same pain in his right side as he had in the left before operation; he manifested a mild delirium. Both were controlled with a single dose of hyosine and morphine.

August 8th.—End of first day. Temperature was 101.6° F.; pulse, 102. Patient appeared delirious; constantly roaming about the room and talking.

2 P. M.—Temperature, 102° F.; pulse, 104. Outside dressings changed; drain removed.

9th.—Temperature, 102.8° F.; pulse, 114. Restless all night.

10th.—Temperature, 100.8° F.; pulse, 86. Feels excellent.

11th.—Temperature, 99.8° to 101.4° F.

12th.—Temperature, 99.8° to 100.6° F. Few sutures removed; skin absolutely healthy. No discharge. No evidence of fluctuation.

13th.—Temperature normal. The patient requested to go home. The wound was absolutely healed, and, as his interests demanded his return at the earliest date, it was deemed safe to discharge him in the care of his physician, Dr. Senn.

The entire left half of his face was free from pain immediately after the operation, also the conjunctiva and cornea. Pain in his neck and post-cervical region had disappeared. He was able to take solid food on the third day and would have done so earlier had he been allowed.

No preliminary suturing of the eyelids was done, but great care was taken to keep the lids closed with a pad of gauze moistened with salt solution. The day he was allowed to return his left eye was sealed up with a watch glass. I am indebted to Dr. Senn and Dr. McIntosh for the history since the patient returned to his home.

It will be observed that the temperature for four days was of such a nature as to lead one in ordinary operation cases to suspect an infection. Had it not been

for the fact of seeing the statement by Tiffany in his last article in the *Annals of Surgery*, vol. xxiv, that "in some cases temperature is high at first, due evidently to basal disturbances involving the heat centres," I am certain that I would have opened the wound on the second or third day. As it was, it required all the courage I could command not to interfere, and, as the temperature began to drop on the fourth day, evidently the wiser course had been pursued.

29th.—Dr. Senn says: "His eye is all right. No taste in the left half of the tongue whatever. Sense of skin contact about the ear and in the flap region, otherwise no sense of pain or contact in the left face."

September 8th.—Dr. McIntosh writes: "The patient is looking much better, having gained from ten to fifteen pounds. Had some peculiar sensations in the face, which are all disappearing."

October 1st.—Word was received that his left eye had been enucleated for corneal ulceration. Dr. McIntosh says: "This would not have been necessary had the patient observed the instructions given him in reference to the care of his eye. But, owing to complete anaesthesia, dust, etc., was blown into the eye and trauma resulted; also he did not report to the doctor until he found his vision affected in the left eye. Otherwise the patient is in an excellent state of health, etc.; no pain, etc."

It will be observed that a period of seven weeks elapsed before corneal ulceration occurred, and it is also noticeable that, four weeks after the operation, while still observing the ordinary precautions about his eye, it was in a normal state.

In looking over the literature it has been observed that corneal ulcerations are usually due to foreign bodies coming in contact with the cornea, and for this reason temporary suture of the lids as a protective agency for a few days is advised. In my case such procedure was not deemed necessary, but a pad moistened with normal salt solution was made to retain apposition of the lids. In addition the eye was thoroughly cleansed every forty-eight hours. No evidence of inflammation or destruction of the conjunctiva or cornea was noticed, and, as stated above, a watch glass was sealed over the eye when the patient was discharged, by this means avoiding trauma from cinders, etc., on his long journey home.

The sense of taste is not lost in all cases, but was noted in this one immediately after the operation. Although with a little care the motor portion of the third division can usually be seen, no attempt was made at a dissection in this case, as the third portion seemed a solid mass, and it was feared that filaments of sensation would be left behind. Naturally, it is advisable to leave the motor filaments, especially if both sides are involved, and also in view of an operation being demanded at a later day on the opposite side.

The question of replacing the bone flap is not so important as would seem at first thought. It has been found necessary on several occasions to reopen the cranium, as in those cases in which but one root was removed, or when the second and third roots were removed and the ganglion. In cases in which the

bone had been replaced some difficulty was met with in the secondary operation, while in several others by Tiffany, in which the bone was not replaced, secondary operations were performed with ease. In Tiffany's cases in which bone had not been replaced it was found that the temporal fascia made an ample protection to the underlying tissues.

The prognosis in these cases sums itself into immediate and remote results. The immediate results are relief or death. Under the former, the question of a partial or complete recovery has to be considered. If the ganglion remains, or is but partially removed, the recurrence has been shown to be more than likely; while, if the entire second and third divisions and their respective portions of the ganglion are removed, complete recovery can be assured. Death as an immediate result has taken place in several ways: *Shock* attending the operation and due chiefly to loss of blood. *Hæmorrhage* being so profuse as to be impossible to overcome its evil effects, although with the methods of saline infusion this latter cause is now rare. Finally, sepsis, with concurring meningitis, due either to lack of cleanliness of the operative field or to the introduction of organisms through the agencies of the fingers, instruments, or dressings.

After the operation there may be *recurrence*, due to incomplete removal or inability to remove the ganglion, as cited in one instance, a case of Dr. Fowler's;* *destruction* of the eye, as cited in the case to-night, due to carelessness on the part of the attendant or patient; *motor paralysis* of the muscles of mastication, due to removal of the motor portion of the third division, this in itself being a serious complication only when both sides are involved; *brain abscess*, resulting from rough handling during the retraction of the brain from the field of operation.

Certainly this mortality rate is not so high but that this method of obtaining relief for so serious an affliction should be advised in all cases, barring the very old and feeble, in which the usual remedies, medicinal and mechanical, have failed, and particularly so if the method of pushing strychnine to its toxic effect, as advised by Dr. Dana, proves unsuccessful.

The rate of mortality has been variously estimated at from 8.7 to twenty-two per cent. The author's collection of seventy-six cases of operation by the Hartley-Krause method by various operators, both American and foreign, gives the following results: Deaths, fifteen; recoveries, sixty-one; mortality, nineteen per cent. plus.

149 WEST FORTY-FOURTH STREET.

An Electric Hot-air Oven.—Dr. R. W. Lovett (*British Medical and Surgical Journal*, April 20th) describes a form of oven heated by electricity for the hot-air treatment of joints. It is said to afford greater comfort than the gas oven.

GASTRODIAPHANY IN THE INFANT.*

By HENRY KOPLIK, M. D.,

ATTENDING PHYSICIAN, GOOD SAMARITAN DISPENSARY,
AND ADJUNCT ATTENDING MOUNT SINAI HOSPITAL (CHILDREN), NEW YORK.

GASTRODIAPHANY—that is, transillumination of the stomach in infants—has been hitherto but little employed as a diagnostic measure. True, we find some few attempts in the literature at gastrodiaphany, but they have been made with but little method and no distinct end in view. The instruments employed have been primitive and unsafe for the infant at least. The best work has, so far as the literature is at my disposal, been done by Finkelstein. This author comes to no definite conclusions. Personally, I have felt the need in certain exceptional sets of cases of a safe instrument with which I could make a modified physical examination of the stomach, determine its size, whether it is dilated or not, the situation and, if possible, the condition of the pylorus. Thus far I have been much encouraged, and think we have in gastrodiaphany of the infant's stomach a means of diagnosis which in the hands of the expert will lead to indispensable enlightenment in trying cases. We are favored in the infant by many things not present in the adult. The thinness of the abdominal walls allows of a much more distinct picture than would be possible in the adult. For this reason, and the much more important considerations of employing every known means at our disposal for a diagnosis, I was induced to spend much time and patience in the perfection of the instrument which I wish to describe.

The Instrument.—When I looked around for a model from which to evolve the instrument here presented, I studied the Einhorn instrument and also

that called the Heumeter instrument. I had at first constructed an instrument which followed the Einhorn model closely, but it was, of course, much smaller. The immediate objection to this instrument was, first, that it was, speaking of infants only, a very unsafe in-

* *Annals of Surgery*, vol. xxiv, Tiffany, Case 32

* Read before the Society of Alumni of Bellevue Hospital, February 1, 1899

strument to use. From this point of view I found that the Einhorn instrument, with its exposed glass bulb at the end subjected to pressure and manipulation in its introduction, might at some time break. The bulb

is smaller in diameter than the metallic portion (five millimetres), and fastened on the metallic portion or head in such a manner that any manipulation will not make tension on the electric wires which run through

Actual size of stomach of an infant six months old with symptoms of pyloric stenosis.

might even come off in the stomach. This would be a serious accident. Then, again, I found that the bulb became overheated; also that the making and breaking of the current could not be made quickly enough, and the whole instrument became quite warm. My instrument presents a very safe form of light, fully protected, like the cystoscope, with a metal cap which protects the glass-work fully and beyond the possibility of breakage. The light, by means of an instantaneous arrangement for making and breaking the current, can not become heated to any degree. It can be run like the cystoscope with an inexpensive dry-cell outfit. It can be introduced into infants of tenderest age.

Description of the Instrument.—The instrument which I have devised consists of a metallic head and a rubber catheterlike body. The metallic portion containing the light is exactly four centimetres long (an inch and a half) and six millimetres in diameter. Its size thus is that of the catheter ordinarily used to wash the stomach of the infant. The rubber flexible portion of the instrument is twenty-seven inches long, a lit-

tle smaller in diameter than the metallic portion (five millimetres), and fastened on the metallic portion or head in such a manner that any manipulation will not make tension on the electric wires which run through the rubber portion. The conducting wires are made quite long and run through a handle as in the Einhorn instrument, but differing in that the current is made by means of a spring instead of a sliding arrangement. Instantaneous opening and closure is thus possible and overheating can be avoided. The light is contained in the metallic end of the instrument, which is fenestrated in a manner similar to that of the barrel of a hypodermic syringe. The light which is contained in the metallic portion is a seven-volt light of four-candle power, and is protected by a glass hood inside of the fenestrated portion of the metallic head. The extreme tip of the instrument is rounded off. It will thus be seen that there is nothing about the instrument which ordinary handling can break.

I regard the instrument in its present form as a very useful and practical instrument whose introduction into the stomach does not subject the little patient to the slightest danger or to more inconvenience than the introduction of the tube for washing the stomach. I have found the instrument of use in clearing up the

following obscure set of cases. An infant is brought to the physician with the story that it vomits constantly; it has steadily emaciated. Every time it takes the breast or its bottle the mother says it not only vomits but seems sometimes to reject much more than is taken into the stomach at that feeding. The infant in a majority of cases is ill nourished; in two of my cases exceedingly atrophic. If the infant is bottle-fed it will develop that almost everything has been tried. Examination of the abdomen reveals a very queer state of things in some of these infants. We find coils of gut clearly outlined on the abdomen, and in two of my cases I found to the right side of the median line a constriction between two distended portions of abdominal contents, apparently gut. The peristalsis of the gut is very marked in these cases. These markings of the gut are quite large, and one of them being to the left and just underneath the ribs and the other to the right, separated by a constriction. I

stalsis of the stomach. This is scarcely so. It is increased peristalsis, but of the gut, including the large intestine. The gastrodiaphane in these cases reveals the stomach in an entirely different locality behind these coils. The constant vomiting in these cases is a cause of the increased activity of the gut. The gastrodiaphane in one of my cases showed distinctly a pylorus in the median line as a transverse thickened line, so that it may have been hypertrophied. It showed also this narrow part of the stomach beneath and behind the coils of gut which were forward to it and running transversely. Again, in these cases I found no dilatation of the stomach—that is, in the cases of continual vomiting coming under my care and examination. All of these points are exceedingly useful. The gastrodiaphane will reveal a stomach dilatation in a quicker and simpler way than measuring stomach capacity by means of a graduated funnel. This presupposes that you fill the stom-

Stomach of an infant five months old with symptoms of stenosis. Actual size. * Where the globe of light could be pushed along the greater curvature.

at first took these phenomena as indicating the increased peristalsis of the stomach. Indeed, if we look over the literature of so-called stenosis of the pylorus in infants, we will see this described as increased peri-

stalsis of the stomach. This is not only painful but very unsafe. Again, I have frequently found that a stomach would hold a hundred and fifty cubic centimetres and at another time fully twice the amount, depend-

ing upon the contraction of the stomach and abdominal muscles and the pressure used. I advise against this method. The gastroduaphane is a harmless method of at once ascertaining the general size of the stomach. In all the cases thus far examined I found the pylorus quite constantly in the midline in young infants, and in a few cases behind the liver. As a rule, however, it is found lower down, just beneath the border of the liver. The stomach lies horizontally, with the great curvature beneath the ribs on the left side, the picture unobstructed by the spleen normally.

There are two things which can be quite distinctly mapped out by this instrument; they are the pylorus and the greater curvature.

The greater curvature in very young infants will be found to lie quite transversely, and, the bulb of the instrument being introduced to the bottom of the stomach by careful manipulation, it can be passed along the greater curvature to the pylorus. The light is seen to clearly outline the greater curvature from the outside by the observer as a very bright spot traveling transversely across the abdomen and then upward, stopping at the pylorus. This occurs quite uniformly in the median line. Thus any adjacent illumination of gut is distinctly differentiated and the size of the stomach as shown by the depression of its greater curvature very distinctly outlined.

The instrument, therefore, gives us a means of finding out the exact size of the stomach, and also possibly the condition of the pylorus, whether thickened, broadened, or narrow. Whether the instrument will aid us in diagnosing growths or glands in the omentum or mesentery remains to be seen in the presence of a definite case. Such a case has not yet offered. The operation of gastroduaphany is carried out in a dark room or under an improvised dark canopy or tent.

Method of Using the Instrument and Marking out the Stomach.—The stomach of the infant is washed out, and, when the water returns clear from the catheter, we reintroduce about an ounce of water—the babe lying horizontally on its back—and proceed to the introduction of the instrument. It is introduced much in the same manner as the stomach tube, but in cases of a projecting epiglottis or seventh cervical vertebra it is necessary to guide the head of the instrument by the index finger of the left hand introduced into the mouth of the infant. Great gentleness should be used, as we are introducing a metallic instrument and are apt to scratch the parts if care is not exercised. Once introduced, we carry the instrument down to the great curvature. Electric contact is then made, and the examiner will find exactly the situation of the instrument. With an aniline pencil the stomach can be outlined, as seen in charts, to be recorded by means of tracing cloth laid over the abdomen later on. When electric contact is made, it should be but for short intervals—a few seconds—then broken and then made again. In this manner

the instrument does not become heated. The withdrawal of the instrument presents no difficulties. The instrument thus far has been employed by me as a diagnostic measure in very young infants, below the age of six months. Its limit of usefulness would extend to infants below the twelfth month. Beyond this age the little ones would become so unmanageable that the difficulties of introduction of the instrument and observation would be great. In children the terror of the little ones would warn us not to push matters unless we cared to use an anæsthetic. I doubt the justifiableness of such a procedure. Again, I have made it a point that this instrument should not be used except in extreme cases—cases which ordinarily fall into the hands of the pædiatrist and in which all ordinary means have been exhausted.

NOTE.—The canopy mentioned is improvised by covering the ordinary photographic tripod with an oilcloth, which will exclude light and furnish the necessary dark chamber.

66 EAST FIFTY-EIGHTH STREET.

THE TREATMENT OF SYPHILIS.

By BOLESŁAW LAPOWSKI, M.D.

(Concluded from page 564.)

THERE is one form of syphilis, the malignant stage, when mercury in any form is inadvisable. In such cases iodine preparations alone or with quinine are of great value. Iodine can not be regarded as an indispensable remedy in syphilis, as patients had been relieved from their syphilitic manifestations before iodine was in use. It does not keep off the earlier symptoms nor preclude relapses. But it is of great use in syphilis, and its value is well expressed by Keyes: "No means in the physician's hands place him so near the Deity as the iodide of potassium." The effect it produces is due to the stimulant action of iodine *in statu nascendi* upon the general functions of the tissues.

An organism in a normal condition has only a slight power to free iodine from its salt, but this power is increased in the presence of staphylococci and many other microbes (39); and herein lies the explanation of the indications for the use of iodine salts in syphilitic manifestations—namely, when the products have a tendency to fatty degeneration or to pus formation, as gummata, hypertrophied papules of the early period, or primary ulcers with a gummatus appearance. It is also advisable to give iodine in early syphilitic affections or organs not accessible to a direct examination, for in such cases it is impossible to determine whether the symptoms are due to changes characteristic of the early or late stages of syphilis. Of all the iodine salts potassium iodide is chiefly used; but recently it was suggested to replace it in some cases by iodide of rubidium which is more easily tolerated and less disagreeable to the taste, and by iodylacid (40), which, not so readily giving up iodine to the system, does not so often produce the un-

desirable effects of iodine as the other salts, a fact appreciated by patients who have to take iodine for a long period.

Iodine as administered for therapeutic purposes is not absorbed by the mucous membrane of the stomach, but by that of the intestines (41); consequently, the way of administration which will not postpone the evacuation of the stomach contents into the intestinal canal is the best. For this reason potassium iodide administered in a liquid form and much diluted with water, taken on an empty stomach, right before meals, will best answer our purpose, and by administering iodine in large doses (two to four daily) we will better avoid its undesirable effects than when given in small doses. The disagreeable taste can be corrected by a mint drop in the mouth or by some mint water.

The acute outbreaks of iodism usually appear on the mucous membrane of the respiratory organs, while the skin is commonly affected in cases of long-continued use of iodine, presenting various kinds of symptoms, as acne, purpura, erythema, and pemphigus. Iodine preparations in the early manifestations of syphilis are only indicated in special forms of the early stage, and during the existence of special symptoms, as headache, pains in the bones; while in the late stage of syphilis the administration of iodine is a classical rule of treatment. It is always advantageous, I may say imperative, not to limit ourselves to the use of iodine alone, but also to give the affected system the benefit of mercurial action. This is usually done by administering the so-called mixed treatment.

The combined administration of iodine and mercury is usually arranged in one of the following five different ways:

First, combining the two remedies and administering them simultaneously.

Second and third, giving them separately on the same day, or on alternate days; and

Fourth and fifth, giving a series (eight to ten) injections, and then, after a rest for eight or ten days, administering iodides, and *vice versa*.

Here is a point for consideration:

From clinical observations we have learned to avoid external applications of mercury to an exposed surface of mucous membrane, while iodine is being taken internally, because a toxic combination—bimiodide of mercury—will be formed at the place of contact of the two ingredients, and produce a caustic action upon the surface of the membrane. The same happens if iodine and mercury are used at the same time externally to different parts of the body (42). Is it not possible that a toxic combination of the two chemical elements is formed in the organism when iodine *in statu na. coli* happens to meet mercury? (43). Some clinicians express the opinion that within us this combination does not take place as it does on the surface of the skin.

But this is an opinion, and one not in accord with clinical observations. In view of this, can it not be asked, Are not some effects observed during the administration of the two drugs, usually ascribed either to the action of mercury or iodine, due to the toxic combination of the two drugs?

For this reason the safest way of administering and arranging the mixed treatment will be to administer iodine for a certain period (two to three weeks) and then, after an interval of five or six days, proceed with the mercury, as the iodine will be eliminated by the time the mercury comes in contact with the internal tissues (44).

In some cases the syphilitic manifestations would be greatly influenced by mercury and iodine but for the impaired excretory function of the kidneys.

In such cases we can not follow the usual method of treatment, and we must be guided by indications based upon the condition of this organ. The percentage of kidney affections in syphilitic patients is very considerable, but as, on the one hand, the syphilitic affections of the kidneys can not be symptomatically differentiated from kidney diseases due to other causes, and as, on the other hand, the kidneys may be attacked by syphilis during any of its stages, it is advisable in cases where we find albuminuria or cylindruria occurring simultaneously with an early syphilitic eruption to place the patient under the influence of iodine and abstain from introducing mercury into the system. Potassium iodide, hot-air cabinet baths, and special attention to the diet will suffice, until the improved condition of the urine indicates a more active treatment. When albuminuria or cylindruria is found in a late syphilitic patient, with or without syphilitic manifestations, outside of potassium iodide in combination with hot-air cabinet baths, mercury can also be used, when by exclusion of all other aetiological factors the cause of the affection of the kidney can be judiciously ascribed to the syphilitic virus. Especially are the eliminative functions of the kidney to be investigated in pregnant syphilitic women, and, should those organs be found impaired, mercury must not be used, as even the slightest form of mercurial intoxication, combined with the disarranged conditions of the stomach and intestines in pregnancy, will produce abortion. When the kidneys do not show any signs of impairment, a vigorous treatment—innjections—is advisable, as we have to influence with mercury not one but two human beings, and sometimes more. If malaria is associated with syphilis, quinine in combination with iodine will be of more service than mercury, especially where the specific disease occurs in a poor habit of body with unfavorable surroundings.

Mercury and iodine excepted, the main remedies by which the defensive powers of the system can best be brought into play, there are some auxiliary procedures by which the organism can be advantageously influenced in its life struggle against the syphilitic poison—namely

ly, mineral springs and hot and cold water. The beneficial results obtained at the springs are mostly due to the fact that, owing to the tonic and reconstituent action of the bath and the favorable climatic and hygienic surroundings, a more energetic use of mercury can be made. But the hot-air cabinet bath (45) is of special specific value. Since it has been experimentally demonstrated that toxins are removed by sweat (46), the assumption that syphilitic toxins are eliminated by the profuse perspiration to which the patient is exposed during his stay in the cabinet should not be disregarded. And this observation goes to demonstrate the correctness of some popular habits in countries where syphilis is treated by exposing the patients to a long period of sweating, either evoked by the heat of a stove, upon which the Russian remains the whole winter, or by the high temperature of sea sand, into which the native of Haiti burrows for several weeks (47), both of them increasing the production of sweat by drinking hot tea.

Even surgical interference may have to be resorted to in some obstinate cases of syphilis, where only a slight improvement can be obtained from administering mercury and iodine, especially in syphilitic lesions of bones, which are accessible to secondary infections, such as the nasal and frontal bones (48). Satisfactory results are reported from surgical operations even in syphilis of the brain (49, 50, 51), when the disease, to quote Hamlet, "desperate grown, by desperate appliances is relieved, or not at all."

But even the best preparation administered by the most suitable method will be of small benefit to the patient if he neglects, nay, even if he is indifferent to what best increases the defensive power of the system, hygiene and diet. Not to impress upon the patient the great importance of hygiene in the successful struggle against syphilis is more than a mistake on the part of the physician. Everything looking toward the maintenance of the patient's health on the highest attainable level is necessary in the treatment of syphilis. Especially must the patient be guarded against bodily and mental fatigue, the usual forerunners of late syphilis of the nervous system. Regarding diet, some precautions are necessary during active mercurial treatment. The digestive tract must not be irritated by food which is liable to produce diarrhoea, as grains or cereals (52), and a milk diet is especially desirable in the first months of the early manifestations of syphilis in order to help the kidneys to perform their double function—the elimination of the syphilitic toxins and of the absorbed mercury (53).

In the local treatment of accessible syphilitic manifestations asepis is a prime requisite. The avoidance of irritation, either by medicinal preparations or by mechanical means, is peremptory. It is advisable to keep the exposed ulcer covered by means of mercurial plaster in the case of a dry chancre, and to protect the sore, especially of the lips and tongue, from

becoming a source of transmission by powder or the white or ammoniated mercury ointment.

The local action of calomel is excellent in the earlier moist syphilitic manifestations. Great care is to be taken with infectious sores on the lips and tongue, as the danger from frequent transmission is great.

The nitrate of silver, when used, must be kept separate for each patient, as the handle of the caustic itself may transmit the disease; hence as many sticks as there are patients. Chromic acid in five-per-cent. or ten-per-cent. solution will answer excellently; but better still is a one-per-cent. solution of sublimate in ether and alcohol (hydr. bichlor. corr., 0.3; ether. sulph. alcohol, 15.0).

Here perhaps is the place to consider the treatment of mercurial stomatitis. Owing to its toxic action, chloride of potassium is to be employed sparingly or, better, not at all. For it we can substitute boiled water with or without borax, bicarbonate of sodium, etc. In severe cases of stomatitis the sovereign remedy is ten-per-cent. iodoform gauze stuffed in the pockets of the mouth.

Although the plan of treatment suggested by bacteriological progress did not come up to the expectations of physicians, yet the abortive treatment of syphilis was given great consideration and prominence as a result of laboratory investigations. But the hope that we could cut short or mitigate the course of the disease by exercising the ulcer at its earliest appearance was far from realized. The syphilitic poison is not entirely removed from the system by excision of the sore, even with its adjacent swollen glands, since the inaccessible glands are also involved in the process, as proved by autopsies on subjects with primary lesions.

Furthermore, microscopical examinations demonstrate not only that tissues near the ulcer are changed by the syphilis, but that the blood-vessels and perivascular lymph spaces are involved; and these two roots of a syphilitic chancre are affected at a considerable distance from the primary lesion (54). Even the blood itself is changed during the appearance of the primary sore, showing a diminution in the amount of hæmoglobin with a normal number of red blood-corpuscles (55, 56, 57). It is then not to be wondered at that there is on record not one successful attempt to abort syphilis by excising a classical ulcer. Thus, careful observation antagonizes any attempt to cut short the natural course of syphilis.

Not so with the other attempt to check the development of the syphilitic virus by early calling into action by means of mercury the natural defensive powers of the organism. Here it is claimed that logic and reason, if not observation, point to the administration of mercury just as soon as the poison has entered the system. It is assumed to be unreasonable, even laden with dangers for the patient's future well-being, to wait for early syphilitic manifestations in order to step in with the mercurial treatment. The action of a physician

who institutes the mercurial treatment only when the syphilitic eruptions appear would be more than irrational if the assertion be credited that the simple appearance of an ulcer means the presence of the syphilitic poison in the system, even when the ulcer is accompanied by all its accessories.

So long as we know from clinical observation that manifestations of an early syphilitic character may follow a mere scratch on the penis or an innocent-looking herpetic vesicle without any perceptible gland trouble, and, on the other hand, that a hard ulcer with a retinue of swollen multiple glands disappears without being followed by any syphilitic manifestations, it is wiser to wait for manifestations upon the skin and mucous membranes before making a positive diagnosis. Granting even the claim of some physicians, who, by virtue of their clinical experience, allege they can recognize a primary syphilitic ulcer without waiting for skin or mucous membrane manifestations, owing to that mysterious, undefinable something which is called clinical instinct, nevertheless the administration of mercury in this stage can not be rationally recommended until its action upon the syphilitic poison at this period of its development is proved to be, if not beneficial, at least harmless.

The benefits derived from the use of mercury are estimated by its power to prevent or diminish the most dreaded manifestations of late syphilis. Measured by this standard, the early treatment seems to be at best of no value, as shown by the fact that the percentage of late syphilis is not smaller than it was at the time when all primary ulcers, both hard and soft, were treated by mercury as soon as they appeared.

Furthermore, many patients, on whom most careful observations were made, had early manifestations of syphilis aggravated in their course and form, although they were put under the influence of mercury simultaneously with the appearance of the primary sore.

These clinical facts are supported by microscopical examinations of blood of patients to whom it was given from the time of the appearance of the primary sore, and it was found that both the amount of hæmoglobin and the number of red blood-corpuscles were diminished before the appearance of early manifestations; and the observers asked, Is it logical, is it rational, is it right, to render anæmic a living organism which has to sustain a struggle—a serious life-struggle—against one of the most persistent of infectious poisons? The answer is in the question (58).

But success in treatment does not so much depend upon the time when the administration of mercury is begun as upon its intelligent direction after its institution, and one of the most important moments in the course of treatment is to know when to stop it. Unfortunately, in the management of syphilis, to begin does not imply to end. The ideal end of treatment is to stop when the disease is cured.

The question then arises, Is syphilis curable, and, if so, what are the signs by which we can recognize that moment so devoutly anticipated by every victim of syphilis? It is assumed that syphilis may be cured *sponte sua*. Fournier met, in his private practice, two hundred and twenty-one persons who never used any treatment, who never partook either of mercury or iodine, and every one of the two hundred and twenty-one had different late manifestations of syphilis (59).

Now, if one practitioner can meet with such a number, where is the cure *sponte sua*?

But some hug the pretension that by a prudent use of mercury and iodine we can bring patients suffering with syphilis to a certain and complete cure, as syphilis is the most curable disease among all infectious constitutional diseases (60). In support of their pretensions they bring numerous observations of patients, once syphilitics, who feel well, marry, have healthy children, and die without having the slightest symptoms which could suggest the presence of a syphilitic diathesis.

The first three occurrences happen in persons who nevertheless develop late syphilitic manifestations in after life. The value of the last point will be best demonstrated by remembering that the importance of late syphilitic affections of some viscera, as lungs and heart, in causing death, was recognized by the medical profession only in recent years, and that we hardly know even at present any infallible symptoms by which we could differentiate syphilitic affections of the foregoing organs from other diseases of the same organs without an ocular post-mortem examination, supported by microscopical discoveries.

Even the fact of reinfection (so often mentioned as an infallible proof of the curability of syphilis) can not be so regarded, when we consider the statements of two of the most eminent living syphilographers, Hutchinson and Fournier. While the English syphilographer was so fortunate as to meet with more than one hundred and eight cases of reinfection (61), the French *savant* acknowledges that he did not even meet one undoubted case of a second attack of syphilis (62). In view of these two divergent statements we must admit something wrong in diagnosing reinfection; what one calls a second attack of syphilis, the other accepts for a relapse of the old disease, and so long as this difference in recognizing such an important factor in the establishment of the curability of syphilis exists, the present generation of physicians will be guided in what they hope to accomplish in their treatment of syphilitic patients by the opinion of Ricord, one of the greatest lights in this realm of medicine, who said that neither the dose, nor the preparation, nor the length of treatment gives us the assurance that the disease is completely, absolutely, and radically extinguished.

In view of this statement, the aim of the physician in instituting the treatment is primarily to prevent

the appearance of the late manifestations of syphilis, which usually involve the vital organs of the system in the destructive process. The physicians try to accomplish this desirable end by one of three methods.

Some—the so-called opportunists—administer mercury only when manifestations of the disease are present; some keep patients under the influence of mercury not only when the manifestations are present, but continue its administration for several years. Others give mercury not only when symptoms are present, but also when they are absent—when, as it were, the disease is latent—leaving a sufficient interval between the times when the drug was given for the system to have a chance of eliminating what mercury has been absorbed; thus preparing the tissues so they may respond to the stimulating action of the drug when it is again given.

Further, since they are unable to distinguish between a possible extinction of the disease and a latent condition of the syphilitic poison, some of them, acting logically, advise the use of mercury as long as such a doubt can possibly exist—i. e., for life; others, again, limit the number of years to two or six, trusting that they may accomplish the desired end in this short period, owing to the vigorous treatment they have prescribed.

Thus we see that the adherents of the three methods do not differ to any great extent for the first two years of treatment, as during this period of the natural course of syphilis several series of relapses usually take place, and the patient will have all the advantages of the drug under the care of either. The difference begins during the second year after the outbreak of the earliest syphilitic manifestations. While the opportunist waits for the appearance of syphilis in order to administer mercury, believing that the length of the intermissions in the treatment should correspond with the periods of intermission in the manifestations of the disease, the advocates of the other chronic, intermittent method would keep the same patient under the influence of mercury for years—both being prompted in their actions by the desire to keep away from the patient the danger of late syphilis.

The opportunist believes that the probable benefits the patient may derive in the future from the administration of mercury during the absence of symptoms are far fewer than the inevitable dangers associated with a prolonged use of the drug even during prolonged intervals.

The advocate of the chronic, intermittent method holds that the probable dangers to which the patient exposes himself by absorbing mercury for a prolonged intermittent period are insignificant, compared with the serious rôle late syphilis may play in the patient's life. That some of the dangers, as albuminuria, stomatitis, which may follow the administration of mercury, can be avoided by strict observation of the patient's condition is not questioned by the opportunists, but they

still hold that the prolonged and repeated stimulations of the cell by mercury have a deleterious effect upon that most delicate structure, and consequently upon its function, giving rise to nervous symptoms, which are usually seen in workers exposed to the prolonged action of the drug and, not seldom, in patients stimulated by mercury for a prolonged even intermittent period.

Furthermore, they state that the adherents of the chronic intermittent method have failed up to date to establish their claim that mercury by their method acts upon latent symptoms and prevents the appearance of late syphilis.

It is proved by numerous reports that the percentage of late syphilitic manifestations is not less—other conditions being equal—in countries where the chronic intermittent method is the chief one, than in countries where the opportunists have their sway. Nay, the percentage obtained by both methods is not smaller than the percentage in countries where mercury is employed very little or not at all (64).

The advocates of chronic, intermittent treatment always bring to the front, whenever the reasonableness of their methods is questioned, the fact that a father at one time syphilitic and treated by mercury immediately before his marriage, even without any symptoms being present, will engender a healthy progeny, while the same father not treated would in all probability bring into the world

"A curious frame of Nature's work,
A floweret crushed in the bud,
A nameless piece of babyhood."

This fact, a proof to the adherents of the chronic, intermittent method of the direct action of mercury upon the virus and of its utility in the latent stages where no symptoms are present, is met by the following statement of the opportunists:

First, that a father, even when he is not treated, may procreate during the flourishing stage of his early syphilis a healthy child; secondly, that a father with latent syphilis, whose child was born perfectly healthy, because of treatment previous to precreation, may in the next or a subsequent year have syphilitic progeny. This proves that neither does mercury act directly on the syphilitic virus, nor is it the only factor influencing the power to produce a latent syphilis.

The need of giving mercury to make sure we can prevent this hereditary transmission is all the greater since there are no precursory signs for us to recognize (such as in the heart and brain affections in late syphilis, when necessary precautions can be taken to prevent irreparable visceral damages), not even a shadow of a symptom to warn us, until we are at once confronted with the accomplished fact of the action of the syphilitic virus.

Every physician must for this reason take into consideration the possibility of hereditary transmission as

a kind of an invisible symptom, when under his care is a patient who is going to procreate offspring.

It is seen thus that a patient derives no more benefit from the chronic, intermittent method than from the symptomatic plan of treatment; and, moreover, is exposed to the influence of an inorganic element, alien, at best, to the organic matter of the body, if indeed it be not baleful.

28 WEST FIFTY-NINTH STREET.

THE PREVENTION OF HAY FEVER.

By EDWARD W. WRIGHT, M.D.,
BROOKLYN.

In recent years hay fever has become more amenable to treatment as a result of careful and thorough study of all the causes that produce it.

It has been decided by the best authorities, American and European, that hay fever is a total or partial loss of control of the small nerves which regulate the size of the blood-vessels in the nose (vasomotor paresis). This condition accounts for the profuse watery discharge, the paroxysms of sneezing, the occlusion of the nose, and all the other distressing derangements so well known to the sufferer.

If these small nerves by any means regain control of the blood-vessels relief is obtained at once.

Every artery in the human body is surrounded by

the tiny tendrils of a nerve. The nervous force carried along these branches adjusts the calibre of the vessel to the conditions required. In hay fever the nervous force carried by these small nerve ramifications is less than normal; therefore the blood-vessels are dilated and the interior tissues of the nose are engorged with blood.

The blood supply of the nose is peculiar. Ordinarily, the blood supply to the skin, mucous membranes, muscles, and organs is uniformly distributed; but in the nose there are clusters of blood-vessels (erectile vascular tissue).

Lying on the lower scroll bones in the interior of the nose, and covered by the mucous membrane, is a nest or congeries of blood-vessels. In other parts of the nose small clusters are found.

In hay fever the nerves controlling the calibre of the blood-vessels have partially or totally lost their power. Consequently, the vessels and the surrounding soft tissues become engorged with blood. This increase in size of the blood-vessels and the adjacent tissues presses upon and stretches the nerve endings of the sneezing area, and paroxysms of sneezing result. Through reflex action the pressure on hypersensitive areas by the engorged tissues excites the excessive sneezing. The osmosis of the serum from the dilated vessels produces the free watery discharge. In like manner can all the symptoms found in hay fever be explained.

Our inquiry in this article will be, "What causes this loss of nerve control of the blood-vessels?" and the discussion will pertain to the cooperation of the different causes.

There are three cardinal divisions of causes: (a) Exciting; (b) constitutional; (c) local.

Exciting Causes.—The exciting causes are "pollen," dust, smoke, and similar irritants. The popular reason for hay fever is the irritation of the mucous membrane of the nose produced by the "pollen" of flowers and grasses. It has been proved, however, that there are other irritants which are exciting causes. Neither "pollen" nor any of the excitants will produce hay fever unless the local and constitutional causes are present. During a residence in a locality where there are no exciting causes no hay fever will arise, because one of the cardinal causes is removed. Also, if one of the other two chief causes is absent, no hay fever will come, though the exciting causes are abundant.

There is a drug which, sprayed in solution in the nose, will cause contraction of the blood-vessels in *all* persons; but "pollen" or the other excitants falling on the mucous membrane of the nose will, in only a small minority of persons similarly exposed, cause dilatation of the blood-vessels. If the excitants were the *only* cause, they would produce hay fever in the majority; but they do not, because one or more of the other cardinal causes are absent.

To sojourn in a district where there are no exciting causes gives immunity only while residing there. That

the affliction may be permanently relieved, we must secure a condition that will resist the exciting power of "pollen," so that a person may be free from hay fever in any locality and pursue business and pleasure without fear or restriction.

Constitutional Causes.—The relation between the vascular system and the nervous system is intimate. In seeking for further causes of the impaired nerve control of the nasal blood-vessels we would naturally consider the nervous system.

Most of the sufferers from hay fever are persons of high intellectuality, having a nervous organization of great tension. They respond quickly to slight neurotic influences. Often the first attack occurs when the nervous system is below par. Perhaps social duties have been exhausting; or grief, or financial reverses, or severe illness, or worry incident to the wear and tear of life, or heavy business responsibilities have so overtaxed the nervous system that it is incapable of performing fully all its functional duties. Thus the way is prepared for a deranged nervous action upon the blood-vessels when the exciting causes arrive.

Frequently recurring headaches, neuralgias, and functional nervous disorders may so lower the nervous organization that the nerve supply of the blood-vessels is impaired.

To have the best resisting power when the time comes for the appearance of the exciting causes, the nervous system must be at par. That the general nervous system may be in the best possible condition, it is well to do everything to lessen the high tension resultant from continuous social obligation; to minimize the worries of business, and to restrict those conditions which demand too great an expenditure of nerve power.

Nerve tonics may be necessary to restore the loss of nerve tone, or gentle soothing medicine to lessen the strain incident to the overtaxation of the nerves. Perhaps some recreation in new fields, or relaxation from the strain of social or business life, would be effective.

Circulating in the current of blood, and also deposited in the tissues of the body, are found substances that have deleterious effects. These substances—viz., uric acid, xanthine, and hypoxanthine—are the products of imperfect digestion and assimilation. They are not readily soluble, and are with difficulty excreted from the system. When one or all are in excess in the system they have an irritating influence on the small nerves that control the size of the blood-vessels. These by-products are undoubtedly another factor in the series of causes which produce hay fever.

There are several medicines well adapted to the elimination of these excitants, and there are, also, ways of living conducive to their prevention.

Local Causes.—Within the nose are frequently found deviations from the normal, which form another link in this chain of causes. Not only is their presence a contributory cause in the onset of the disease, but dur-

ing an attack they aggravate the distress. These deviations and abnormal conditions have a marked influence on the blood current of the nose and form sensitive areas, the irritation of which affects, by reflex action, the small nerves controlling the diameter of the blood-vessels.

Polypi, large and small, spurs, minute and exaggerated, bony or cartilaginous projections from the septum, a swollen middle turbinated bone, a grayish enlargement of the posterior end of the inferior scroll bone, a thickened condition of the tissues on the lower edge of this bone, hypersensitive areas at some point of the interior of the nose, or a general catarrhal condition of the mucous membrane following the curves into the nooks and crannies of the interior nose, are the main points that must be thoroughly investigated. The relation of these variations from the normal standard to the cause of the trouble must be carefully considered.

By gently searing sensitive areas, by the removal of minute projections of bone or cartilage, by cauterization of hypertrophied tissue, by the removal of polypi, many persons have been cured. To attack indiscriminately every variation from the standard would be poor surgery; to overestimate the importance of a bony projection would be an error; but the relation of cause and effect must be studied carefully in each individual case. Having placed the interior of the nose in the best possible condition, we have prepared the way to give this local region the strongest resisting power against all exciting causes.

We can render the mucous membrane less sensitive, or non-sensitive, to "pollen" or other irritants, give it greater resisting power, and make it immune against the exciting causes by a method that may be termed massage treatment. This treatment came about in the following manner:

In reviewing the chemistry of hypoxanthine, the statement was found that it was present in the "pollen of flowers and grasses." By blowing powder of hypoxanthine into the noses of patients who had had hay fever, it was attempted to excite the symptoms of that condition; but it could only be said to be an irritant. Then the powder was used to render the mucous membrane accustomed to it. Knowing the good effects of tannic acid in eyelid affections, and the beneficial results of iodine in the pharynx, it was decided to use one or both of these in the nose, applying it with gentle friction over the whole mucous membrane of the nose, but more especially to the usual sensitive areas. When there was a thickened condition of mucous membrane and a hypertrophy of parts beneath, iodine, potassium iodide, and glycerin were used. When the mucous membrane was thin, sensitive, with no appearance of hypertrophy, tannic acid, carbolic acid, and glycerin were applied. These, in weak solutions, were thoroughly applied with gentle friction to all the nooks, crannies, and surfaces of the interior of the nose, but

more particularly over the usual sensitive areas, that part of the septum opposite the middle turbinated, and that part of the soft palate just behind the septum. Sometimes it was necessary to use a very weak solution of cocaine in fine spray before a thorough massage could be accomplished. The object of these applications and the friction by massage is to harden the mucous membrane, giving it greater resisting power, and thus an immunity against "pollen" and other excitants—just as cold sponging and friction with coarse towels to a sensitive skin enables the person to wear undergarments that formerly could not be tolerated.

For the treatment of an attack of hay fever two new drugs promise well—orthoform and suprarenal capsule. Orthoform will allay the supersensitiveness, the hyperæsthesia, and the paroxysmal sneezing. Its effects are in duration many times longer than cocaine, and it has no toxic action. When we wish to give the patient free breathing through the nose and lessen the serous discharge, the use of a solution of suprarenal capsule will accomplish the desired result without the disadvantages of cocaine.

Thus a happier and pleasanter summer should be promised the patients who come at the beginning of their annual distress.

To tide these persons well over a season is a break in the "habit," and prepares the way for effective preventive treatment before the time of the expected attack of the next season.

GOLD IN THE TREATMENT OF ANÆMIA AND MALNUTRITION.

By J. P. SHERIDAN, M.D.

A JUST equilibrium of the processes of tissue destruction and reconstruction is absolutely essential to vital force. Through the consumption of its own tissues the body generates heat and vital energy, and from water, air, and particularly food, the cells build up new tissues and store up fresh supplies of material to feed the never slumbering furnace in which this vital transformation is wrought. Truly, adequate nutrition may justly be said to be the prerequisite of physical perfection.

The word "anæmia" means, literally, bloodlessness, and our best authorities say it may be produced by a variety of causes. It will be the object of this paper, however, to point out the fact that after all it is due to malnutrition. The great source of blood supply is the stomach; for the quantity and quality of the blood in the body depend chiefly upon the ability of that portion of the economy to digest and assimilate food. Anything, therefore, which prevents the taking of sufficient food, or interferes with the digestion of food in-

troduced into the stomach, will produce bloodlessness. The degree of bloodlessness will depend upon the length of time and the degree of interference with the source of nutrition.

Among the early symptoms of anæmia we find such conditions as constipation, headaches, palpitation of the heart, exhaustion after the least exertion, lassitude, or, in the infant, a change in the color and frequency of the stools. The stools are either green when passed, or become so later on. Bacteria, according to Lesage, cause the change in color. The frequency of the stools is marked, the quantity is lessened, but the discharges are offensive and irritating. As further evidence of the faulty metabolism, we have other symptoms indicating auto-intoxication.

Blood analysis will show in both the adult and infant a diminution of red blood-corpuscles and an increase of leucocytes; diminished hæmoglobin. A large number of the practitioners of the day treat these cases expectantly—namely, with iron and digestive ferments and plenty of syrups; naturally, the condition becomes more distressing. Syrup of iodide of iron and the various æsthetic elixirs are simply convenient placebos—involving a waste of time. What these patients need is a tonic alterative and proper food.

It is through the cells that the tissues must be built up, and I have found the best preparation to be the liquor of bromide of gold, arsenic, and mercury—mercauro. Results, in the large majority of cases treated with this product, are simply astonishing. Children of six months of age who are anæmic and do not appropriate their nourishment can easily take two drops three times a day and fatten like little pigs. Mercauro is practically tasteless, can be dropped in the milk, and is without doubt a good tonic and reconstructive for the anæmia and malnutrition of infancy and childhood. Another class of cases in which this solution gives most gratifying results is that of slow convalescence after pneumonia, either catarrhal or lobar. I recall the case of a little girl of eight years of age whose parents were sorely distressed for fear that her great debility, which continued after a bad attack of catarrhal pneumonia, might lead to tuberculosis, as this disease was a family inheritance. This child was treated with mercauro and the dose rapidly increased to eight drops three times a day. In two months she was the picture of perfect health. It has been my definite experience that mercauro overcomes anæmia more promptly and more effectually than any form of iron or manganese does. My experience applies to the anæmia of malaria, of tuberculosis, of chlorosis, of childbearing, and of syphilis. Those of us whose practice is extensive among syphilitics have, I feel sure, an excellent preparation in mercauro. How often have we had to suspend all mercurial treatment on account of the fearful anæmia produced by innctions or the protiodide in the treatment of secondary symptoms! The old way was to put the

patient on iron, quinine, and strychnine, but, thanks to the practitioners at Hot Springs, Arkansas, it has been demonstrated conclusively that iron, quinine, and strychnine absolutely do no good except to satisfy the patient that he is swallowing something.

Now mercauro is used with the result that all manifestations of the disease disappear, and the patient, to all intents and purposes, is perfectly well.

A girl aged twenty years had run down from various causes. She came to consult me, being introduced by a lady who had been a patient of mine.

A prominent gynecologist in this city had treated her for over six months. She had a profuse leucorrhœa, with the usual pain in the back. She had paid her doctor sixty dollars, and again at another time forty dollars, and told me she had taken plenty of iron pills and iron mixtures. I treated her with arsenauro. The result at the end of two months is gratifying, though not a surprise to me. She has no leucorrhœa—in fact, is perfectly well. Her only medication was arsenauro administered in fifteen-drop doses in half a goblet of water after each meal.

In cases of too frequent menstruation arsenauro has brought about regularity and cured dysmenorrhœa; it seems to restrain congestion of the sexual organs and should be considered in chronic diseases of menstruation. It has a deservedly high reputation in certain disorders of the reproductive organs of women. In chronic vaginal leucorrhœa, with general weakness and relaxation, arsenauro is of special value. Good results may be looked for in cases of chronic uterine inflammation with marked tendency to relapses. The best effects are obtained when the full physiological action becomes manifest.

POSITION IN SLEEP.

A PRINCIPLE IN NEUROLOGICAL THERAPY.

By WILLIAM BROWNING, M. D.,

BROOKLYN.

DESPITE the proportion of our lives spent in slumber, sleep symptoms contribute but an insignificant part to our clinical data. If such exist, it is common remark that they have almost entirely eluded investigation, nor have physiological studies so far yielded much for the physician. As most vital processes are at an ebb in sleep, we need expect no large mass of independent manifestations, yet there must be some of importance. The matter of dreams has so involved the whole subject of sleep in mystic speculations that we forget to apply simple observation just as to any other matter of living. The processes of life go on during sleep under the same physical laws as at other times. Our medical examination in the waking state takes very little account of the subject's thought, barring the single field of insanity, and in the sleeper it does not matter to us medically what the person dreams. If we can ignore all this, except, perhaps, the mere fact of dreams occurring or

not, and give attention to the actual manifestations of the sleeper, a valuable accession to the clinical side of medicine may be the result.

While there are a number of sleep matters that call for more study and recognition, I wish to direct attention to one that has specially interested me in its relation to nervous diseases.

Certain general considerations may serve to introduce the real subject of this paper. If, e. g., a person is fainting, we do not lift the head, much less get the sufferer upright, but insist on a fully prone position and keep the head low. Again, if we have to resuscitate a patient from anæsthesia, the same plan is followed—we lower the head as much as possible. If a person is prostrated by hæmorrhage, we utilize gravity as an aid to the depleted vessels in sending the needed supply to the brain. Or, when a very weak patient is suddenly lifted, if only to the sitting posture, we know but too well the risk of fainting or even death. Hence it is a well-recognized fact, at least in conditions of general weakness, that the brain circulation is greatly affected by the position of the body and especially of the head. The same principle has long been applied in neurology as part of the so-called rest cure.

These illustrations from the waking state are close parallels to certain sleep conditions. If a person when sleeping prefers to rest with the head unusually low, it is a natural indication that the circulatory and nutritive conditions of the brain are below par.

At any rate, if we look through the wards of a hospital during sleeping hours, or if we observe and question our patients carefully on this matter, we soon find a great diversity of habit regarding the favorite position in sleep.* This applies to adults; in children it is naturally much less apparent.

We have no very exact standard for measurement. But for practical purposes the following classification may suffice:

I. The medium class—persons who sleep with the head on an ordinary or thin pillow and bolster. This may be termed normal and represents the average sleeper. A few persons voluntarily change their custom in this regard and seem to mind it little. All this class can be dropped from further consideration.

II. Those who sleep with the head higher than this standard (bolster plus thick pillow, or plus two pillows, or plus a doubled-up pillow, on an arm, etc.). In some this occurs chiefly when they have been mentally engaged just before retiring. It may be further specified that not infrequently such individuals begin with the head high but gradually slide down as

* To this subject in certain special cases the writer has repeatedly called attention—first, perhaps, in describing a form of morning headache (*Brooklyn Medical Journal*, 1894). Further study, now covering a dozen years or more in all, has shown that the principle applies much more widely. It represents an objective fact, and one that we can usually get at.

the night progresses, and end in the morning with the head medium or even low.

Such persons can not well tolerate any elevation of the feet in sleeping. And this shows also that the position of the head is but a part of the general attitude of the body.

In this category are found cases of excitement, mental overactivity, mania; also a proportion of neurasthenics, epileptics, and nondescripts; besides, of course, many persons who present no special nervous disturbance.

Separate from this class are the various diseases and conditions—such as valvular disease, asthma, fever, advanced dropsy, and perhaps abdominal encroachment—that for special reasons induce their subjects to rest with the head high, irrespective of the principle here presented. Such cases have to be carefully distinguished, and to that extent this class is inexact. For instance, in a recent case where there was grave exhaustion in an asthmatic, the patient slept at medium height, an average between two opposing factors.

III. Those whose habit it is to sleep with the head lower than the usual average. Some of these sleep with the body perfectly flat—neither pillow nor bolster. Of about equal significance is the custom, followed by an occasional individual, of sleeping on the belly, the face turned to one side.* This last habit is oftener resorted to for only a portion of the sleeping hours. Possibly those who sleep with the arms thrown up over the head also belong here.

This (III) class of persons show with greater or less frequency a number of allied characteristics. They are less apt to be given to dreaming. Their sleep is usually profound; in fact, they crave an extra amount. They incline to waken drowsy, tired, and exhausted, and the sounder the sleep the more lethargic are they on awakening. Breakfast has no charms, and their appetite only comes for later meals. If inclined to headache, this is present, and often most severe, on waking, and the condition termed "waking numbness" is oftenest encountered here. Coffee, breakfast, exercise, and perhaps a cold morning rub get them finally roused and in possession of their powers.

Such persons want their feet in sleep on a level with the rest of the body, or even higher; and with them cold feet are not the great impediment to sleep that they are when present in Class II.

Here we find nearly all cases of mental and nervous depression, sufferers from simple melancholia, anemias, and most chlorotics, the special headache cases, those who have been heavily depleted, convalescents from long illness, so-called hypertonic paralytics, many neurasthenics and hysterics, some epileptics, etc.

* A gifted colleague sleeps on his belly, but with the forehead resting on one arm. He alleges that he thus imitates primitive man, since our wandering ancestors must usually have lacked pillows, and so have eked out a head rest with the arm.

Of course, between these three groups many mixed forms (perhaps a majority even of the neuroses cases) are encountered, not falling entirely in either.

In earlier medical days much was said of sthenic *versus* asthenic disorders. Modern pathology has largely done away with such distinctions in the general run of diseases. But in these nerve cases something suggestive of this old view can be made out.

Is this again simply an attempt to rehabilitate the old conception of cerebral anemia or hyperemia? Possibly it amounts to that; but the matter is approached in a different way, and in any case with a basis of actual facts. The practical bearing of these observations is the same whether the proffered explanation is correct or not.

The question may arise whether this sleep condition, however real, is or is not a true index of waking states. Apparently not always; but if we are able to follow such cases for a series of years much will become evident in support of the view that we have here a trusty index of underlying conditions.

And similarly it may be queried whether this is not a habit innate or family affair, with as little clinical importance as, say, color blindness. But such supposition is negatived by the fact that a patient's custom in this respect may change, and also by the wide difference often of the members of one family.

It is, of course, true that people in fair health may exhibit any of these peculiarities. Even in them it shows tendencies, and when occurring in the sick this has a practical bearing.

In such cases as show aberration from the normal in this respect, an indication or criterion is afforded to help us in selecting our remedies. It does not represent a disease, but a rule for determining the general brain condition underlying and doubtless in part causing the special form of disease from which the patient is suffering.

Let us see how it works. The third type (head low) is the more important because naturally the more frequent in the sick. Here the indications are for remedies that either essentially or casually are excitants and tonics. Hence *nux vomica* and its derivatives, *digitalis*, *strophanthus*, and other cardiac tonics, the *valerianates*, *viburnum*, increase of body fluids, alcoholic stimulants, iron, arsenic, and blood builders, overfeeding, rest, come within the range of our choice. On the other hand, we shall find little good here from depressants, whether hypnotic or otherwise.

All this is reversed in the second type of cases (those with head high). Here the field for selection includes, on the contrary, the numerous more or less depleting and depressing remedies, such as *aconitine*, *atropine*, *hyosine*, chloral, bromides, *sulphonal*, *phlebotomy*, warm baths and sweat cures, diaphoretic and expectorant agents, hard work, etc. But all excitants, stimulants, and tonics are contraindicated.

The bearing of this principle on the more important general hygienic regimen of the patient must be clear without further specification.

There are other drugs and agents frequently employed in neurological work that do not fall distinctly in either group, and that consequently may be resorted to independently of this rule. It will also sometimes occur that other and more imperative indications force us to ignore this plan, or more often to combine so as to offset the untoward effect of some desirable drug. In the numerous cases where this principle applies we can readily avail ourselves of it, and where it does not it can be disregarded. I have found it useful in many cases, and feel that it is so simple and trustworthy that it may be worth a trial by others.

Therapeutical Notes.

Powders for Ovarian Neuralgia.—Martin's formula is given as follows in the *Riforma medica* for March 25th:

R Extract of belladonna 3 grains;
Extract of stramonium $4\frac{1}{2}$ "
Lactophenine 90 "

M. Divide into twenty powders. Two or three to be taken daily.

Carron-oil Injections in Gonorrhœa.—W. E. Wamsley (*Brooklyn Medical Journal*, xiii, p. 182; *Merk's Archives*, March), of Brooklyn, at the suggestion of a patient, has tried linimentum calcis as an injection in gonorrhœa and gleet with unusually good results. The patient had used it for a burn and it occurred to him that it might be good in gonorrhœa. The doctor at first paid no attention to the suggestion, but later gave it a trial. He has since used it in twenty-seven cases of acute specific urethritis after a three-days' treatment with the compound copaiba mixture of the *National Formulary*, using it four times a day, and in every case a cure was effected in three or four days. In nine cases of gleet a complete cure was accomplished in from seven to nine days with the carron-oil injections only. The author warns against the danger of this emulsion becoming rancid if kept long, and advises that it be used only when freshly prepared.

Antineuralgic Powders.—The *Riforma medica* for March 25th gives the following formula:

R Quinine hydrobromide 15 grains;
Extract of nux vomica 3 "
Phenacaine, { each 6 "
Eulguine, {
Bayer's powder, {

M. Divide into six powders. Two to be taken daily, before meals.

Pepsin in Burns of the Third Degree. O. Waterman (*Therapeutische Monatshefte*, xii, p. 30; *Merk's Archives*, March), of New York, gives the history of a case of a machinist who received a burn of the third degree caused by some boiling pea soup which was spilled over his left forearm. This was at first treated with

carron oil and next day with iodoform gauze. At the end of three or four days the wound was covered with a dirty whitish purulent secretion with raised edge. Some places were curetted. Pepsin was then sprinkled over the arm and the whole surrounded by a gauze bandage. At the end of four days this was removed and the wound surface was studded over with healthy granulations, and here and there new patches of epidermis had commenced in this short time to develop. The wound was then again cleaned with antiseptics and another sprinkling of pepsin applied. At the end of about twelve or thirteen days the whole arm was healed and there was no scar tissue. It is also to be noted that the patient was anæmic and was suffering from *tabes dorsalis*.

An Elixir of Terpene for Bronchitis.—The *Riforma medica* for March 27th attributes the following formula to Crinon:

R Terpene, { each 10 parts;
Tincture of vanilla, {
Glycerin, {
Alcohol, { each 150 "
Syrup of honey 125 "

M. S.: From two to four soup-spoonfuls to be taken in the course of twenty-four hours.

Chlorethyl Freezing Mixture in Hæmophilia.—Davies (*Brooklyn Medical Journal*, xiii, p. 182; *Merk's Archives*, March), in the case of a patient who was a known "bleeder," immediately on the extraction of a tooth sprayed the cavity with chlorethyl freezing mixture. The blood that first entered the cavity froze into a hard mass, effectually plugging it and preventing further hemorrhage. This procedure he has frequently repeated successfully.

The External Use of Phenacaine in Rheumatism.—The *Revista de Ciencias medicas de Barcelona* for March 25th ascribes the following formula to Taylor:

R Phenacaine 75 grains;
Lanolin 300 "
Olive oil q. s.

M. For an ointment.

Or—

R Phenacaine 75 grains;
Rectified alcohol, { of each 1,500 "
Hot water, {

Compresses may be soaked in this solution and applied hot.

For Spasm of the Glottis.—Friedrichs is credited by the *Revista de Anatomia patológica y Clínica* for February 1st and 15th with the following:

R Extract of belladonna 44 grains;
Anisated solution of ammonia, 375 "
Distilled water 225 "

M.

From ten to twenty drops every three hours in spasm of the glottis.

Compound Wine of Creosote for Tuberculosis.—The *Revue médicale* for April 12th credits the following prescription to Fraenkel:

R Creosote 195 grains;
Tincture of gentian 450 "
Alcohol 3,750 "
Sherry..... enough to make 1 quart

M. Two or three tablespoonfuls to be taken daily in beginning pulmonary tuberculosis when the temperature does not exceed 101.3 F.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 6, 1899.

THE ULTIMATE DISPOSAL OF THE CASE-BOOK.

THE *British Medical Journal* has recently made some noteworthy comments on a matter that seems to us of great importance, that of the disposition that should finally be made of clinical records. Our contemporary's article, which appeared in its issue for April 8th, hinged on an odd incident the account of which had been published in *Truth*. The story was that twenty-one manuscript volumes of notes of cases treated by the late Dr. Alfred Meadows at the Soho Square Hospital for Women had been sold in a "lot" at public auction, and that a gentleman who had been present at the sale, thinking this an improper transaction, had taken the trouble to remonstrate with the hospital authorities, but to no purpose. *Truth's* comment on the matter was: "Setting aside all sentimental considerations, there are necessarily many facts in such books which would afford an opening for the most iniquitous practices if they got into unscrupulous hands." The *British Medical Journal* practically coincides in this, but thinks the danger of real harm occurring is very small, beyond the rendering of certain persons uneasy. Clinical notes, it argues, are usually made in highly technical terms and with great use of abbreviations, so that they would not be readily intelligible to blackmailers; moreover, persons of the class who seek hospital treatment change their place of abode frequently, so that it would put a mischief-maker to some trouble to find them. This is true, no doubt, but unscrupulous persons are not lazy as a rule, and we fear they would have little difficulty in inducing some medical acquaintance to explain technical expressions and abbreviations.

The article closes as follows: "The books of a women's hospital would be less worth investigating than those of almost any other, for an illicit pregnancy is almost the only lever for a blackmailer in such patients, and that is a thing that can hardly be concealed. It is conceivable that a book full of histories of the other sex, in which inquiries as to syphilis had been regularly made, might be very dangerous to the peace of the patients if used by an unscrupulous person. Those who take such notes of private patients are well aware of this. The unscrupulous person searching hospital

case-books might not find his knowledge so profitable as he hoped, and might, as we have hinted, find unexpected consequences, but he nevertheless might be troublesome. Therefore, we repeat, it is the bounden duty of those who manage hospitals to see that notes of cases are either kept in safe custody or destroyed."

It may be that among hospital patients an illicit pregnancy can hardly be concealed, but we doubt if the difficulty of its concealment is very great in the case of private patients as a rule; indeed, we are sure it is not. This leads us to remark that it is not hospital records alone that should be jealously guarded or else destroyed, but those of private practice as well. Perhaps, as the *British Medical Journal* intimates, greater care is taken to make the records of private cases obscure than is observed in noting down the points in hospital cases; but no amount of caution in that direction, short of making the notes in a language known only to the writer, can, it seems to us, make it sure that those records can do no harm if they get into the hands of designing persons. It is to be presumed that every careful practitioner keeps at least skeleton histories of certain of his cases, and it is our conviction that he should keep them carefully secreted so long as he continues in practice, that he should destroy them if at any time he retires from practice, and that on his death they should be destroyed at once without examination. We may add that what is an individual's duty in this respect is also the duty of a hospital. We can not suppose that the late Dr. Meadows would have considered himself at liberty to sell the records of his hospital practice, and we can not see that the hospital had a moral right to do so after his death.

THE PRESENT STATUS OF THE VAGINAL PESSARY.

WHEN a topic seems to have been practically neglected for a considerable length of time, it is well to have it investigated anew, even if, as is the case with the pessary, more than enough has been written about it in bygone years. In the April number of the *Scottish Medical and Surgical Journal* Dr. J. W. Ballantyne furnishes us with an excellent review of the subject of the use of vaginal pessaries in the treatment of prolapse and faulty posture of the uterus—we prefer not to term this last-mentioned abnormality displacement, although there is sometimes an ectopic element in it.

It is evident from the answers to Dr. Ballantyne's inquiries of instrument-makers that pessaries have not fallen into disuse; indeed, for the past twenty years there has been a steady increase in the number sold, but also a steady decrease in the number of varieties asked for, so that the ring and the Hodge or some modifica-

tion of it, with an occasional vaginal stem supported by means of an abdominal belt, are practically the only forms in common use. Those who use the Hodge pessary show a decided tendency to revert to the Albert Smith modification after trying various forms, and those who employ the ring prefer the simple rubber instrument containing watch-spring. Intra-uterine stems are hardly ever asked for.

Without following Dr. Ballantyne in his further treatment of the subject, let us inquire as to how far this state of things is satisfactory, and first as to the continued extensive employment of pessaries. Is the use of a pessary preferable as a general rule to an operation? We believe it is, provided the right kind of pessary is chosen, and provided it is properly managed. We may say at once that we look with scant favor on the ring pessary, particularly one of soft rubber inclosing watch-spring. The action of the spring is apt to be injurious, and soft rubber soon becomes foul in the vagina. The so-called eup pessary we look upon also as highly objectionable, especially when it is so constructed that the vaginal stem simply wobbles on a perineal band. Nevertheless, we think that a properly fashioned vaginal stem, one with a bow like that of the Hodge pessary, so supported by elastic cords passing down from a pelvic belt that the direction in which it presses is under control, and that direction is the right one, is the best of all pessaries. However, a great deal of trouble frequently attends the fitting of it, and the patient has to be carefully instructed in its management. For those reasons the Hodge instrument in its various forms is likely to remain the favorite. In these remarks we have reference only to backward versions of the uterus and to its descent. As for anteversion, the cases are rare that call for treatment, and we think there are better appliances than pessaries for treating those rare instances.

THE VICARIOUS PERFORMANCE OF FUNCTION.

This is an exceedingly interesting subject, but one concerning which our positive knowledge is very limited. We know, of course, in a general way of the reciprocal relations of the skin and the kidneys, but that is not saying much. How largely the matter is still shrouded in uncertainty was well exemplified by a case recently reported to the Paris Medico-surgical Society by M. Pecker (*Presse médicale*, April 1st). It was that of a man, fifty-eight years old, who had had scarlet fever when he was nineteen and sciatitis at the age of forty. For eighteen years he had been troubled with winter cough and respiratory oppression, but one

year diarrhœa supervened and his oppression was at an end.

The man was of alcoholic heredity and given to the use of alcohol himself. His liver appeared to be somewhat atrophied. There was a network of enlarged subcutaneous veins well marked on the right flank, but there was no ascites and the urine contained neither albumin nor sugar. The diagnosis was that of atrophic cirrhosis of the liver. He was treated with potassium iodide, benzonaphthol, tannin, and bismuth salicylate, with the result that his intestinal evacuations became less liquid and less burning.

In October, 1898, after a short railway journey, he felt sensations of cold in his feet and in the loins, also atrocious pains in the region of the left kidney, radiating along the ureter and to the testicle. The pain was intermittent and accompanied with vomiting. At night he had chills, with chattering of the teeth. The kidney was enlarged. The amount of urine voided in twenty-four hours was from six to nine ounces, and it contained traces of albumin. The temperature ranged from 100.4° to 101.6° F. The diagnosis at that time was hydronephrosis, but it was changed to hepatic cirrhosis with renal congestion. In spite of rational treatment, the urine did not increase in quantity, ascites occurred, calling for two tapplings, and finally the man died.

M. Pecker thought the case showed how life could be maintained so long as the organs supplemented each other adequately. The patient bore his cirrhosis as long as the kidney assisted the liver; when the kidney in turn failed, the system gave up the struggle. It was undeniable, he thought, that the diarrhœa had been compensatory; indeed, the man had been thankful for it, for it had caused his pulmonary oppression to disappear, and then the kidney trouble had come on as the result of chilling.

M. Gautrelet suggested that the diarrhœa might have been due to heightened arterial tension, but M. Pecker had always found the tension below normal. M. Berthod thought that a false sense of security was engendered by the idea of compensatory function; one organ, he said, might, indeed, take the place of another temporarily, but not for a very long time, for it became exhausted from the excessive work put upon it. M. Verchère called attention to the uncertainty as to what organ it would be that would take the place of another; when an organ was diseased, he said, all the others that were sound strove to assist it. From all this it will be seen how largely the speculative point of view was taken by those who joined in the discussion, and how little ground there was for any other course.

THE TRANSPLANTATION OF A HUMAN OVARY.

DR. JAMES H. GLASS, in the *Medical News* for April 29th, records a very interesting case. A young woman who had had a double oophorectomy performed some two years previously applied for relief from the train of symptoms, lapse of sexual instinct, mental depression, insomnia, giddiness, palpitations, heat flushes, pelvic pains *et hoc genus omne*, which are not uncommon sequelæ of that operation. General treatment proving of no avail, on May 11, 1898, ventrofixation was performed. A second patient, aged seventeen years, married, having suffered serious injury during parturition, which had resulted in such deformity that future child-bearing would inevitably entail Cæsarean section, it was determined to sterilize her by removal of the tubes and ovaries. On May 14th both patients were, with their own consent, anesthetized together, with the view of transplanting the healthy ovary about to be removed from the one woman into the peritoneal cavity of the other. The healthy ovary, immediately on removal, was placed in gauze kept moist with warm normal salt solution. When the first operation was completed, the vagina in the other patient and the connective tissue down to the cervix were incised. The latter was then stripped up to the peritoneum with the finger, and this membrane carefully raised from its attachments to a point approximating the normal position of the ovary. Oozing was controlled by compresses of hot saline solution, the ovary anchored in position by closing, with two tiers of fine catgut, the canal through which it had been introduced, and the vagina lightly packed with silver gauze. The recovery was uninterrupted. After six days a condition of sexual erethism lasting for several days and accompanied by erotic dreams had occurred. After sixteen days menstruation began and lasted two days. It was then absent until December, when it again appeared and was normal in every way. Eight months after the transplantation the patient had regained her equilibrium, and was apparently quite well and healthy. The value of this observation appears to be considerable; for while much of the patient's relief may possibly be attributable to the ventrofixation, the return of the sexual instinct, the recurrence of the menses, and the improved metabolism would appear to be undoubtedly due to the transplantation of the ovary.

CARBOLIC-ACID GANGRENE.

THE danger of gangrene as the result of carbolic-acid applications is again brought to our notice in the *Centralblatt für Gynäkologie* for April 22d, which cites a case of Frankenburg's published in the *Münchener medizinische Wochenschrift* of unmentioned date. A robust peasant girl, twenty years old, ran against the hub of a cart wheel and wounded her thigh superficially. In an apothecary's shop a three-per-cent. solution of carbolic acid was applied, and gutta serena was laid over all. The dressing was kept on for six days, and then the girl was brought to a clinic, where a patch of gangrene as large as the palm of one's hand was found on the inner side of the thigh. When the eschar came away, there appeared a wedge-shaped vacancy exposing the muscles, and at the end of three weeks healing was not complete.

In the same number of the *Centralblatt* there is also an abstract of an article of Czerny's on the subject, published in the same Munich journal about two years ago

(and noticed by us at the time), in which it was laid down that it was not so much the strength of the solution employed as the length of time it was kept applied that led to gangrene. Manifestly this distinction should be borne in mind, even if we do not go so far, as Frankenburg and Leusser do, as to declare that carbolic acid should no longer be used as a dressing.

A CURIOUS CASE OF STRANGULATION OF THE PENIS.

THERE seems to be no end to the pranks played by fools with the genitals. Dr. Floras (*Deutsche medizinische Wochenschrift*, 1898, No. 28; *Monatshefte für praktische Dermatologie*, April 15, 1899) relates the case of a railway official, fifty-five years old, who, having been "dared" by a companion, wormed his flaccid penis through a thick iron screw-nut having an aperture a centimetre and a half (rather more than half an inch) in diameter, forcing the thing as far as the suspensory ligament; but the organ at once became so swollen that he could not withdraw it, although he made efforts to do so for several days and was aided by a sapient doctor who prescribed a diuretic. When the author was called to the man, the penis "hung down like a monstrously inflated sausage," and was gangrenous in places. Two locksmiths were sent for, and are said to have shown wonderful skill in relieving the man of his burden, though how they did it is not stated in the *Monatshefte's* abstract.

THE RESULT OF GRAFTING WHITE SKIN ON A NEGRO.

CERTAIN investigations of Karg's are mentioned in an editorial article in the April number of the *Southern Medical Journal* as leading to the supposition that a piece of the skin of a white person, grafted upon a black, would gradually become black in the course of time. This, however, says the writer, did not happen in a case of Dr. Stuart McGuire's. A negro's leg had been amputated, and sloughing occurred in the flaps. Grafts from a white man's leg that had just been amputated were employed after Thiersch's method, and more than a year later the transplanted skin was found as white as ever.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

THE association's meetings are always important. The one held in Washington this week was no exception. The programme was a good one, representing eminent practitioners of various sections of the country. An excellent feature connected with the meeting was the previous distribution of printed abstracts of the papers to be read. We are indebted to the secretary for a copy of these abstracts, a number of which we have been able to make use of in this issue.

AN AMERICAN SURGEON'S HONORS FROM THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IT is with great pleasure we record the fact that in April the Royal College of Surgeons of England conferred upon Dr. Frederic S. Dennis, of New York, the rare distinction of the honorary fellowship of the college. The fellowship of the College of Surgeons, one of the, if not the, highest surgical distinctions of Great Britain, has for many years past been obtainable only

after a most rigid examination, though formerly it was an honor conferred by election upon selected members, as the fellowship of the College of Physicians still is. When the change was made, however, the right was reserved of granting two honorary fellowships annually, *honoris causa*, upon selected members of the college of twenty years' standing. This is, we understand, the first time that the honorary fellowship has been conferred upon an American surgeon, though there are many such who are members of the college. Mr. Thomas Frederick Chavasse, a prominent and brilliant surgeon of Birmingham, England, is the other recipient of the honor.

THE "DAVENPORT HEALER."

SOMEbody has been good enough to send us a copy of a publication having the semblance of a newspaper, but devoted to setting forth the healing powers of a certain "Dr. Palmer." This individual not only cures everything in the shape of disease, but takes pupils. Evidently he does not labor long with his pupils, for he says: "Those who can't learn to do what Dr. Palmer is doing in 3 months better not try." In another place he says the student "must use his brains, if he has any." His publication is called the *Chiropractic*, and that apparently is the name of his freakish "system."

THE REVIVAL OF THE PESSARY.

INDICATIONS that the pessary treatment of uterine retroversion is again coming into vogue continue to be found in current literature. We hope that those who take up the use of the instrument will employ it with as much carefulness and attention to detail as are displayed in an excellent article on the subject by Dr. William Mercer Sprigg, of Washington, published in the April number of the *Peoria Medical Journal*. Dr. Sprigg properly insists on the frequent necessity of remodeling the Hodge instrument and its modifications as they are found in the shops, and he cites Fritsch as declaring it "easier to perform a laparotomy than to apply a well-fitting pessary."

ERYTHEMA AS A SEQUEL OF INFLUENZA.

Truly the manifestations of influenza are protean. At a recent meeting of the Paris Hospital Medical Society (*Indépendance médicale*, April 19th) M. Antony reported a case of scarlatiniform erythema occurring during convalescence from influenzal pneumonia, also one of erythema nodosum supervening in the course of bronchopneumonia due to influenza. There was no possibility in either case, he said, that the eruption was caused by any drug. Eruptions occurring in connection with influenza, he remarked, were not rare, but they were generally among the earliest symptoms.

AUTOPLASTY AFTER AMPUTATION OF THE BREAST.

The wound left after latter-day operations for cancer of the breast is sometimes enormous. Certain surgeons have resorted to the device of sliding the other breast with its integument into the chasm. Franke (*Zeitschrift für Chirurgie*, 1899; *Tribune médicale*, April 12th) seems to have improved upon this procedure, especially for cases in which the breast is large. After detaching the healthy breast from the underlying parts,

he excises it, together with its nipple, leaving a flap of integument only, with a central opening (left by the removal of the nipple) through which a drainage tube is passed.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 29, 1899:

DISEASES.	Week ending Apr. 22		Week ending Apr. 29.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	15	7	12	8
Scarlet fever.....	217	16	226	17
Cerebro-spinal meningitis....	0	11	0	16
Measles.....	355	16	306	12
Diphtheria.....	180	26	205	32
Croup.....	13	7	8	2
Tuberculosis.....	191	141	170	178
Small-pox.....	2	1	1	0
Chicken-pox.....	26	0	30	0

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Surgery, on Tuesday evening, the 2d inst., Dr. Marshall Clinton, United States Volunteers, read a paper entitled *The Impressions of a Medical Man in Cuba*.

The Maryland Medical Journal.—In the issue of this journal for April 29th Dr. E. F. Cordell gives a very interesting sketch of the medical and surgical faculty of Maryland from 1799 to 1899, which is illustrated with many reproductions of interesting pictures, etc.

A British View of the Campaign in the Philippines.—*The Lancet* for April 22d says: "The news from the Philippines is no doubt disconcerting, for it shows that the task which the Americans set themselves to accomplish is likely to be much harder and longer than was anticipated. But the pendulum of public opinion swings easily from the side of elation to that of gloom, especially where political sentiment is divided and political capital may be made out of war news. The obstacles and difficulties which the Americans are now facing are such as this and other countries have had to encounter before now and have in the end overcome. Campaigns in tropical countries, where the enervating effects of climate and climatic disease have to be met and where the nature of the country, with every inch of which its inhabitants are familiar, lends itself to ambushes and irregular and defensive warfare, are always difficult undertakings. But eventual success depends, after all, upon the determination and fortitude of the more powerful belligerent, and if the American nation, having once set themselves to the task, have made up their minds not to look back until it is done, then we can not doubt that it will eventually be accomplished."

Death of Sir William Roberts, M. D.—By the death of Sir William Roberts, England loses a distinguished physician. He was the first professor of medicine of the Victoria University when that institution was founded in Manchester from the Owens College of that city. He was a member of the senate of the University of London, and the representative of that university upon the general medical council. He contributed largely to medical literature, especially in relation to diseases of

the kidneys and the digestive organs. The deceased physician enjoyed more than an ordinary share of affectionate respect and popularity.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general for the week ending April 29, 1899:

Small-pox—United States.

Tallahassee County, Ala.	Apr. 14	Prevalent.
Los Angeles, Cal.	Apr. 15-22	6 cases.
Washington, D. C.	Apr. 27	1 case.
Savannah, Ga.	Apr. 17	2 cases.
Origin, Montgomery, Ala.		
New Albany, Ind.	Apr. 15-22	2 cases.
Shreveport, La.	Apr. 15-22	3 "
New Orleans, La.	Apr. 15-22	9 "
Boston, Mass.	Apr. 17-28	6 "
Minneapolis, Minn.	Apr. 9-15	1 case.
St. Paul, Minn.	Apr. 9-15	1 "
Buffalo, N. Y.	Apr. 20	1 "
Elmira, N. Y.	Apr. 15-22	1 "
Allegheny County, Pa.	Mar. 30-Apr. 12	4 cases.
Cambria County, Pa.	Mar. 30-Apr. 12	1 case.
Blair County, Pa.	Mar. 30-Apr. 12	22 cases.
Fayette County, Pa.	Mar. 30-Apr. 12	48 "
Somerset County, Pa.	Mar. 30-Apr. 12	20 "
Washington County, Pa.	Mar. 30-Apr. 12	1 case.
Providence, R. I.	Apr. 21	2 cases.
Galveston, Texas.	Apr. 1-15	10 "
Laredo, Texas.	Apr. 1-8	17 "
Newport News, Va.	Apr. 14-19	9 "
Norfolk, Va.	Apr. 13-26	41 "
Portsmouth, Va.	Apr. 13	10 "

Small-pox—Foreign.

Ghent, Belgium	Apr. 1-8	1 death.
Bahia, Brazil	Mar. 18-Apr. 8	8 cases, 1 "
Rio de Janeiro, Brazil	Mar. 3-10	1 case, 7 deaths.
Hongkong, China	Mar. 3-11	3 cases, 1 death.
London, England	Mar. 25-Apr. 8	2 "
Athens, Greece	Mar. 25-Apr. 8	62 " 32 deaths.
Bombay, India	Mar. 14-21	10 "
Calcutta, India	Mar. 4-18	8 "
Seoul, Korea	Mar. 11	Many cases and deaths.
Mexico, Mexico	Apr. 9-16	10 cases, 4 deaths.
Moscow, Russia	Mar. 25-Apr. 1	20 " 3 "
Odessa, Russia	Apr. 1-8	2 " 1 death.
St. Petersburg, Russia	Mar. 25-Apr. 1	16 " 3 deaths.
Warsaw, Russia	Mar. 18-Apr. 1	5 "
Constantinople, Turkey	Mar. 20-Apr. 10	22 " 1 death.
Smyrna, Turkey	Mar. 12-26	1 death.
Montevideo, Uruguay	Mar. 11-18	1 case.

Yellow Fever.

Bahia, Brazil	Mar. 18-Apr. 1	13 cases, 7 deaths.
Rio de Janeiro, Brazil	Mar. 3-10	91 " 58 "
Vera Cruz, Mexico	Apr. 13-20	4 "

Cholera.

Bombay, India	Mar. 14-21	7 deaths.
---------------	------------	-----------

Plague.

Tamsui, Formosa	Feb. 22-Mar. 8	63 deaths.
Bombay, India	Mar. 4-21	1,128 "
	officially reported.	Probably 1,960 "
Calcutta, India	Mar. 3-18	188 "

The St. Louis Medical Society.—At the last meeting, on Saturday, April 29th, Dr. J. B. Ross read a paper entitled *Antitoxine, Therapeutically Useless and Biologically Faulty*.

The State Civil-Service Examinations.—We would call the attention of our younger readers to the notice given in our advertising columns of competitive examinations to be held soon of candidates for appointments in the New York State hospitals.

Changes of Address.—Dr. James R. English, to No. 239 West Fifty-second Street, New York; Dr. W. J.

Mersereau, to No. 366 Lexington Avenue, New York; Dr. D. F. Monash, from Des Moines, Iowa, to Chicago, Illinois; Dr. William Hallock Park, to No. 315 West Seventy-sixth Street, New York; Dr. H. B. Poinsett, to No. 144 West One Hundred and Fourth Street, New York; Dr. Winslow W. Skinner (formerly of New York), from Ajaccio, Corsica, to No. 2 Piazza degli antinori, Florence, Italy; Dr. Max A. Zipser, to No. 52 St. Mark's Place, New York.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 22 to April 29, 1899:*

BRADFELD, GEORGE M., Acting Assistant Surgeon, will proceed to Governor's Island and report to the commanding general, Department of the East.

GREENLEAF, CHARLES F., Colonel and Assistant Surgeon-General, will proceed to Savannah to superintend the sanitation of the military camps near that city.

MEYERS, SIDNEY J., Acting Assistant Surgeon, will proceed to Louisville and report to the surgeon-general.

MUNSON, EDWARD L., Captain and Assistant Surgeon, is detailed as a member of the board of officers at Washington to examine persons designated for appointment as paymasters, *vice* REED, WALTER, Major and Surgeon, relieved.

PORTER, ALEXANDER S., First Lieutenant and Assistant Surgeon, will report at San Francisco for examination.

A board of officers, to consist of **FORWOOD, WILLIAM H.**, Colonel and Assistant Surgeon-General; **EVERTS, EDWARD**, Captain and Assistant Surgeon; and **RAYMOND, THOMAS U.**, Captain and Assistant Surgeon, is appointed to meet at San Francisco for the examination of officers of the medical department for promotion.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending April 29, 1899:*

BARBER, G. H., Passed Assistant Surgeon. Detached from the Naval Academy and ordered to the *Monongahela*.

HOLCOMB, R. C., Assistant Surgeon. Detached from the Naval Academy and ordered to the *Monongahela*.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending April 27, 1899:*

BAILLACHE, PRESTON H., Surgeon. Granted leave of absence for thirty days on account of sickness. April 21, 1899.

WHEELER, W. A., Surgeon. Granted leave of absence for twenty-seven days from June 4, 1899. April 21, 1899.

BANKS, C. E., Surgeon. To proceed to Vineyard Haven, Massachusetts, New York, N. Y., and Baltimore, Maryland, as inspector. April 27, 1899.

PETRUS, W. J., Passed Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., on May 16, 1899, for examination to determine fitness for promotion. April 27, 1899.

MAGRUDER, G. M., Passed Assistant Surgeon. To report to chairman of board of examiners at Washing-

ton, D. C., on May 16, 1899, for examination to determine fitness for promotion. April 27, 1899.

KINYOUN, J. J., Passed Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., on May 16, 1899, for examination to determine fitness for promotion. April 27, 1899. Relieved from duty as director of the Hygienic Laboratory, Washington, D. C., and directed to proceed, not later than June 1, 1899, to the San Francisco, California, Quarantine Station and assume command. April 27, 1899.

WEITENBAKER, C. P., Passed Assistant Surgeon. To report to the Governor of Virginia for special temporary duty. April 21, 1899.

PERRY, J. C., Passed Assistant Surgeon. To assume temporary command of the service at Port Townsend, Washington, during the absence of Passed Assistant Surgeon C. H. GARDNER. April 24, 1899.

ROSENAU, M. J., Passed Assistant Surgeon. Upon being relieved from duty at Santiago, Cuba, to proceed to Washington, D. C., and assume charge of the Hygienic Laboratory as director. April 27, 1899.

EAGER, J. M., Passed Assistant Surgeon. To proceed to Evansville, Indiana, and Cincinnati, Ohio, as inspector, and to Louisville, Kentucky, as inspector of unserviceable property. April 22, 1899.

BARKER, H. B., Assistant Surgeon. To proceed to Santiago, Cuba, and report to Passed Assistant Surgeon M. J. ROSENAU for duty. April 24, 1899.

FOSTER, M. H., Assistant Surgeon. To proceed to the Brunswick, Georgia, Quarantine Station for special temporary duty. April 27, 1899.

LUMSDEN, L. L., Assistant Surgeon. Relieved from duty as sanitary inspector on the United States transport *Logan* and directed to report to the medical officer in charge of the Savannah Quarantine Station for temporary duty. April 22, 1899. To report at Washington, D. C., en route for Seattle, Washington. April 25, 1899.

RAMUS, CARL, Assistant Surgeon. To proceed to Norfolk and Portsmouth, Virginia, for special temporary duty. April 26, 1899.

Board Convened.

Board convened to meet at Washington, D. C., Tuesday, May 16, 1899, at 10 o'clock a. m., for the examination of passed assistant surgeons to determine their fitness for promotion to the grade of surgeon. Detail for the board: Surgeon CHARLES E. BANKS, chairman; Surgeon J. H. WHITE, and Surgeon P. M. CARLINGTON, recorder.

Resignation.

WHEELER, W. A., Surgeon. Resignation accepted, by direction of the President, as tendered, to take effect June 30, 1899. April 20, 1899.

Society Meetings for the Coming Week:

MONDAY, May 8th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, May 9th: Washington State Medical Society (first day—Tacoma); Nebraska State Medical Society (first day—Lincoln); American Climatological Association (first day—New York); New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, New York, Medical Association; Rome, New York, Medical Society; Medical Society of the County of Rensselaer, New York (annual); Newark (private) and Trenton, New Jersey, Medical Associations; Clinical Society of the Elizabeth, New Jersey, General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, May 10th: Ohio State Medical Society (first day—Springfield); Washington State Medical Society (second day); Nebraska State Medical Society (second day); American Climatological Association (second day); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Pittsfield, Massachusetts, Medical Association (private); Philadelphia County Medical Society.

THURSDAY, May 11th: Ohio State Medical Society (second day); Nebraska State Medical Society (third day); American Climatological Association (third day); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, New York (annual); South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, May 12th: Ohio State Medical Society (third day); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, New York.

SATURDAY, May 13th: Obstetrical Society of Boston (private).

Births, Marriages, and Deaths.

Married.

BAKER—HAYES.—In Brooklyn, on Wednesday, April 26th, Dr. Frank Russell Baker and Miss Louise Rawson Hayes.

COOPER—LEWIS.—In New Orleans, on Wednesday, April 26th, Dr. Webster Herbert Cooper and Miss Nellie Hyams Lewis.

DUNBAR—BISLAND.—In New Orleans, on Wednesday, April 26th, Dr. Joseph Dunbar and Miss Sadie Bisland.

FERGUSON—GRAY.—In New York, on Saturday, April 29th, Dr. J. Burr Ferguson and Miss Pauline Gray.

HICKS—HAMILTON.—In Brooklyn, on Wednesday, April 26th, Dr. John Ravenswood Hicks, of Warrenton, Virginia, and Miss Grace Hamilton.

MAGEE—PARKER.—In Portsmouth, Virginia, on Tuesday, April 25th, Dr. M. d'Arcy Magee, of Washington, D. C., and Miss Margaret E. Parker.

MATTHEWS—MATTHEWS.—In Brooklyn, on Wednesday, April 26th, Mr. John Ames Matthews and Miss Grace Edna Matthews, daughter of Dr. Henry C. Matthews.

PRICE—MOTT.—In New York, on Wednesday, April 26th, Dr. Jacob C. Price, of Branchville, New Jersey, and Mrs. Alice Westbrook Mott.

WILLIAMS—KING.—In Allegheny, Pennsylvania, on Wednesday, April 26th, Mr. Otis L. Williams and Miss Nina Bakewell King, daughter of Dr. Cyrus Black King, of Allegheny.

Died.

GORTON.—In Providence, Rhode Island, on Monday, May 1st, Dr. William Arthur Gorton.

KISSANE.—In Brooklyn, on Wednesday, April 26th, Dr. William E. Kissane.

RAKESTRAW.—In Hicksville, Ohio, on Tuesday, April 25th, Dr. B. M. Rakestraw, in the eighty-first year of his age.

SMITH.—In Bronxville, New York, on Tuesday, May 2d, Mary A. Smith, wife of Dr. David E. Smith, in the sixty-sixth year of her age.

was mistaken; for no sooner had A. S. taken three doses of five grains each than a severe coryza and an intolerable facial neuralgia made him miserable. The pain was especially excruciating in both superior maxillæ.

The lad, not in the least attributing his suffering to the mischievous iodide, came to his brother with his tale of woe. He intended to have some teeth extracted to relieve the agonizing pain in the maxillæ. Upon inquiry it turned out that he had never had a toothache before—in fact, that his teeth were perfectly sound. His brother, the physician, was struck by the similarity of the symptoms to his own at the time of his taking the iodide, and was convinced that they were all due to the iodide. A cocaine spray was resorted to, and with the aid of bromide of sodium and phenacetine A. S. was soon relieved of the unpleasant manifestations of iodism.

It seems to me that the case of these two brothers, manifesting such severe symptoms of iodism after a small dose, is a remarkable one, and would justify one in calling it a family idiosyncrasy of intolerance to iodides.

KATHERINA EOSEROFF-MARYSON, M. D.

THE PERIOD OF INCUBATION OF MEASLES.

April 15, 1899.

To the Editor of the New York Medical Journal:

SIR: In the *Journal* for April 8, 1899, under the heading of Pith of Current Literature, it is related that Dr. James C. Wilson, in a lecture, told of an adult with typhoid fever being placed in an ambulance with a person having measles. On the thirteenth day thereafter symptoms of measles developed in him and the rash appeared on the eighteenth day. The doctor therefore concludes that the incubation period ascribed to measles should be lengthened because in this case the exact date of exposure was known. Now, it is not in a spirit of criticism that I write, but simply to state the facts in an experiment of my own.

Fifteen years ago, in 1884, previous to having studied medicine in a college, I was teaching in the far South. There was in my room an enrollment of eighty and there was an average attendance of sixty-four boys and girls of the average age of seven years. The month was February and the day was chilly, so that the doors were closed. There were six windows, and all of them were open about two inches at the top. At 10.15 A. M. a pupil entered, saying he had come for his books, as his little sister had the measles. By way of parenthesis, let me say here that I was always fond of scientific experiments from my earliest childhood and have often exposed my life in my eagerness for facts. It is not strange, then, that some thoughts went through my mind with the rapidity of lightning. "A good time to test the contagiousness of measles. . . . It's against the rules to let this boy remain in school for the day, but—fifteen minutes—nothing can be said. This boy is well, had the measles himself several years ago. Wonder if he has the contagion in his clothing! Sixty-four children, seven years old—not many have had measles. Am I doing right? Mild climate—measles light always, no danger—I'll try it." Then I said to the boy: "I want to see you a moment at recess. Take your seat till then. It's only fifteen minutes." His desk was exactly in the centre of the room. It could not have been better situated for the experiment. At the end of the fifteen minutes all the children were turned out and made to engage in vigorous exercise in a large playground for the time of recess—fifteen minutes. To make sure that

Letters to the Editor.

A FAMILY IDIOSYNCRASY [FOR IODINE.

95 STANTON STREET, NEW YORK, *April 14, 1899.*

To the Editor of the New York Medical Journal:

SIR: Kindly permit me to report in your valuable *Journal* the following case of extraordinary susceptibility to iodides in two brothers:

H. S., a physician, thirty-five years old, suffering from aortic regurgitation, was advised by his physician to take iodide of potassium, five grains, three times daily. He took the first dose on January 28, 1899, toward evening. Soon after he experienced the onset of an acute coryza. The following morning he took another dose, whereupon his coryza became aggravated. His eyes were suffused and his nose was red and swollen, the mucous membrane being very irritable and discharging profusely. He became somewhat suspicious of the iodide, but, considering the small size of the dose, ventured upon another one in the afternoon. His coryza was now something fearful to behold, and in addition he complained of an intolerable neuralgia of all the branches of the facial nerve. He described the pain as stabbing, tearing, and unbearable, as driving him mad and making him think of committing suicide to obtain relief. He was now convinced that the iodide was at the bottom of the trouble. A two-per-cent. cocaine solution injected into the nostrils gave immediate relief in that quarter; another injection and a dose of phenacetine caused his neuralgia to be lessened in severity, and in a few hours he was as well as ever.

A few weeks later his brother, A. S., twenty-two years old, a drug-store clerk, had some small boils on the nape of the neck. Some one suggested to him to take iodide of potassium. He asked his brother, the physician, for an opinion, and the latter told him to try it, as it would surely do no harm. But in this the doctor

the boy did not come into immediate contact with any one, I sent him immediately home and watched him till he was out of sight.

It was not without some little anxiety that I called the roll every morning after that, but all was serene till the eighth day thereafter, when twenty empty seats greeted my eye. Several more children dropped out each succeeding day till the fourteenth, when there were but twenty-two little ones to answer the roll call. It is needless to say that these had all had the measles before. My own child was among the number out. On the sixth day of absence I took pains to send a messenger with a note to the home of each child, inquiring the cause of absence. The invariable answer was, measles. As the reply came, a little *m* was written in the column for the first day of absence, and forty-two such letters appeared. I have that record book till now, with the names and ages of the children. In a month's time all had returned safe and sound. There were no deaths and no sequelae. The usual time of absence was two weeks.

Now, what was learned by this wholesale experiment? 1. *The extreme contagiousness of the disease.* The child who gave the contagion did not have the disease himself. He had simply come from a home where it existed. He had walked a mile in the open air to get to the school. He came in immediate contact with no one child. He remained in the room but fifteen minutes. The room was ample in size for the number of children and had six windows, all open a little at the top. At the end of the fifteen minutes every child, without exception, was made to exercise for a time in the open air. In spite of all this, every one not immune by previous attack took the disease.

2. *The degree of susceptibility* was shown also, for it was not those who sat nearest the infected child that were first to leave. The empty seats were scattered all over the room.

3. *The period of incubation* was shown to be from eight to fourteen days, according to the degree of susceptibility. It may be argued that all did not contract the disease from this exposure. To this I will reply that there was not an epidemic of the measles at the time, that twenty children came down with the disease on the same day—the eighth—after the exposure, and that in six days thereafter there were forty-two children absent with the same disease. All this would point to the schoolroom and the single exposure as the cause of every attack.

I have just one question to ask of the doctor. Does he think it best to use the case of an adult in making estimates and formulating facts concerning a disease which is essentially a children's disease? The adult is not so susceptible as the child, and, besides, in the case noted the patient had another acute disease, which would tend to make him still less susceptible. Is that not the case?

SARA NEWCOMB MERRICK, M. D.

TYPHOID FEVER AS A CAUSE OF EPILEPSY.

CHAS. COLONY, SOMER, N. Y., April 13, 1899.

To the Editor of the New York Medical Journal:

SIR: In an editorial note in the *Journal* for April 15th I noticed that M. Dide, in the *Revue de médecine* for February, considers that typhoid fever plays a very prominent part in the etiology of epilepsy. From personal experience in the examination of several hundred epileptics in America, I have seen but one case where

typhoid could have been urged as a causative agent in the slightest degree; in this case there was a marked neurotic predisposition. I am quite certain that in the experience of my fellow epileptologists in America typhoid fever acts less frequently as a cause of epilepsy than almost any other infectious disease or fever.

It is comparatively common to see many varied forms of mental disturbance, such as mania and melancholia, follow typhoid. Taking this into account, the rarity of typhoid in the etiology of epilepsy is quite phenomenal.

L. PIERCE CLARK, M. D.

THE CITY BOARD OF HEALTH AND THE SALE OF ANTITOXINE.

NEW YORK, April 24, 1899.

To the Editor of the New York Medical Journal:

SIR: I have taken a deep interest in the question of the municipal sales of the laboratory products of the department of health, as any taxpayer must who takes the trouble to look at all closely into the details of the expenditure of public moneys. My interest has been heightened by the communications of five hundred medical men in the city and fifteen hundred in the State who have signified to me their support of the measures recently before the legislature seeking to remove the objectionable provisions of the charter under which this municipal commercialism is permitted. This shows clearly what is the sentiment of the medical profession at large and when free from the personal solicitation of the very few to whose interest the continuance of the present system is important.

In the discussion there has been no desire to bring any adverse criticism on the department of health as a department, for it is recognized that the health commissioners are doing their best under very trying conditions. At no period of the discussion was any effort made to impugn the quality of the antitoxine made by the department of health. The only thing which could bear that construction was an offhand statement of Commissioner Cosby before the assembly committee on affairs of cities. A great deal more prominence has been given to this statement made in the heat of debate than it really warrants. Dr. Cosby was intent on meeting a question which seemed to tend in the direction of proving that the selling branch of the department had adopted such trade methods of competition as cutting rates in Chicago. Rather than permit that impression to go unchallenged, Dr. Cosby, taking up a transaction with which he could not be wholly familiar, as it had taken place under a previous administration, unguardedly made some statements which might be taken as implying that the antitoxine was inferior in quality. His own explanation of his remarks is the very natural one that he is not accustomed to so speaking, and said things which he never intended to say.

Since the defeat of the bill in the legislature Colonel Murphy, the president of the department, has accorded a hearing on the subject to a deputation of physicians and others interested in the matter. He was very cordial in his reception and displayed abundant desire to correct anything which should bring the department under the criticism of the medical profession. The objections to the present system were presented to his careful consideration, and his many questions showed that he was trying to get at the bottom of the topic. Several of the deputation addressed him at more or less length, and thus was presented a wide range of opin-

ion, not only of the medical profession and professional journalism, but of important business organizations. It was not expected that Colonel Murphy would render his decision then and there, for his only purpose in the meeting was to accumulate a mass of forceful opinion which should aid him in coming to a settlement of the matter in his own mind. But he did express his thanks to those who had called on him, and he assured them that what they had said would have due weight with him, and that his determination would be announced at as early a date as was compatible with full study of the best procedure. In conclusion, he dismissed his callers with the assurance that when his decision was reached they would not find it disappointing to them.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XVII.

RIGHT TO COMPENSATION; FAILURE TO BENEFIT PATIENT
NO NECESSARY BAR TO RECOVERY OF COMPENSATION.

(Continued from page 612.)

Illustrations.—Whether or not a physician has complied with the requirements of the law in a given case is a question of fact to be determined by the jury by the aid of expert evidence. In a recent Illinois case the evidence showed that the patient was thrown from his buggy and his left shoulder joint dislocated by the fall. On the following day he called upon the doctor, who, the evidence tends to show, properly reduced the dislocation. In three or four days he called again, according to the physician's instructions, and the shoulder appeared to be doing well. The patient was not again seen by the physician for about forty-five days, when the shoulder was found to be in an ankylosed condition, and unable to be moved. On the following day the patient returned to the doctor's office by appointment; the doctor administered anesthetics to him and proceeded to break up the adhesions, but in doing so ruptured the axillary artery. The next day the physician and patient went to Chicago, where an eminent surgeon performed a surgical operation on him. He cut down upon the blood-vessel, cleaned out the cavity, which was filled with blood clot, sought out the bleeding vessel, tied it, sewed up the wound, and dressed it. He testified that the head of the humerus was in the socket where it belonged. The patient never fully recovered from the injury, and, as the evidence tends to show, his arm is stiff and the humerus out of place.

The physician brought suit to recover his fee, and the patient contested it on the ground that the dislocation was never in the first instance reduced, and that caused the ankylosis and the necessity of breaking up the adhesions from which the subsequent trouble resulted. The patient also contended that if the shoulder had been properly reduced in the first instance, and ankylosis had set in, it was not proper practice to break up the adhesions; that he would have got proper motion in the lapse of time without it. The doc-

tor introduced the evidence of several of the most eminent physicians of Chicago, who gave their opinion that the treatment of the patient's wound was good practice at every step. Upon the advisability of breaking up the adhesions, one physician testified as an expert witness as follows: "Patients don't always get the benefits that we hope they will get in cases where the shoulder has been dislocated, but that advice was such as a surgeon in good practice would give under the circumstances."

The evidence also tended to show that the surgical operation necessitated by the rupture of the axillary artery was the probable cause of the shoulder becoming again dislocated.

The jury concluded from the evidence that the physician had treated the patient's shoulder in a reasonably skillful manner according to the practice of surgeons, and accordingly gave him a verdict. The appellate court sustained the verdict, and, in commenting on the case, said: "A physician is not an insurer of the success of his treatment, and is entitled to pay for his services whether he succeeds in curing his patient or not, provided he uses the skill of an ordinarily skillful physician."*

In a Tennessee case of some years ago an amputation was performed with a large butcher knife and a carpenter's sash saw as the surgical instruments. The operation, however, appeared to have been well performed, and the patient, under a proper treatment, soon recovered. The representative of the patient contested the collection of the physician's fee upon several grounds. The court held that the operation seemed to have been performed with a reasonable degree of skill, and accordingly sustained the verdict of the jury giving the physician his fee. The supreme court, in commenting on the case, said: "It certainly requires some degree of skill in anatomy and surgery to perform an operation of the kind, and the success that attended it, though not conclusive, is a circumstance from which the skill may be inferred. The instruments employed, drawn from other vocations, not the most congenial for the special occasion, were certainly unusual and extraordinary for such a purpose. But we are not to infer from this circumstance alone that the surgeons had not sufficient art and skill in the use of them. Besides, it is possible that the delay necessary to procure proper instruments might have been fatal to the patient."†

It does not necessarily follow that a physician has failed in performing his legal duty to his patient, and is therefore not entitled to compensation, because he has mistaken the nature of his disease and treated him for an ailment from which he is not suffering. In a recent case brought in New Jersey by a physician to recover a fee, the defendant interposed the defense that the physician had prescribed and administered remedies for a disease which he had not. The trial justice instructed the jury that this insistence of the defendant, even if true, would not prevent a recovery; that the question was whether the physician exercised proper care and skill as a physician; that if the jury should conclude that the doctor was mistaken in the nature of the defendant's disease, they must go still further, and say that a want of care and skill was exhibited. If no want of care or skill appeared, he was entitled to a fair compensation, although he fell into a mistake. This is undoubtedly a correct statement of the law, and in

* *Yunker vs. Marshall*, 65 Ill. App., 667.

† *Alder vs. Buckley*, 1 Swan (Tenn.), 69.

applying it to a given case it remains for the jury to determine whether or not, as a matter of fact, the physician has failed in bringing the proper amount of knowledge to the case or did not exercise a reasonable and ordinary degree of skill and care.*

Effect of Incompetency or Neglect upon Right to Recover.—Whether a physician's failure to possess the proper degree of learning and skill, or neglect to use proper care in their exercise, does *ipso facto* preclude him from all right to compensation is a question upon which there is a direct conflict of authority.

The courts of New York hold that such failure on the part of the physician does defeat all right to compensation; and as a corollary to this proposition they hold that a judgment obtained in a suit for the value of services in a given case conclusively establishes the propriety of the physician's treatment in that case, and that an action for malpractice can not afterward be based upon the same case.† The supreme court of Maine expresses itself in harmony with the New York courts and this proposition when it says: "The same facts which would authorize a recovery for malpractice would constitute a defense in a suit for professional services."‡

In a later case, in Wisconsin, the court repudiated this doctrine, and held that the physician's claim for fees and the patient's claim for damages resulting from malpractice were two separate and distinct claims.⁴ The doctrine laid down by the supreme court of Wisconsin has been approved and followed by a recent case in Iowa. The court in that case says: "It does not necessarily follow that because a physician or surgeon may be guilty of negligence, which causes some inconsequential or inconsiderable injury, he is to be deprived of all compensation for his services on account thereof. Whether he shall lose the value of his services depends upon the amount of damages suffered by reason of his neglect to perform his duty. No penalty beyond the amount of the actual damages sustained is to be visited upon him because of his negligence or want of skill."||

The latter doctrine is thought to be the better law, and the Iowa and Wisconsin cases will probably be followed as precedents by the courts of those States which are not already committed to the contrary doctrine.

(To be continued.)

Pith of Current Literature.

New (Platinum) Method of Obtaining a Black Reaction in Certain Tissue Elements of the Central Nervous System.—Dr. W. Ford Robertson (*Scottish Medical and Surgical Journal*, January) describes the following method of staining nerve tissues, which, judging from the beautiful plates that accompany his article, must be highly effective. He says that he has made a number of experiments on tissues hardened in a ten-per-cent. solution of formalin (which is a forty-per-cent.

solution of formaldehyde in water) in solutions of platinum, palladium, and silver. The salt of platinum that he has employed is the bichloride. He finds that the reaction obtained varies in certain respects in accordance with the proportion of formalin that is added to the platinum solution. Provisionally, he recommends that the fluid employed should be made by the addition of five per cent. of formalin to a one-per-cent. solution of platinum bichloride. A piece of tissue is placed in about twenty times its volume of this fluid. The bottle should be corked, but not tightly, as it is necessary that air should not be entirely excluded. In from one to three months the piece of tissue begins to blacken. It must, however, be allowed to remain in the fluid for several weeks longer, during which time the process of blackening proceeds so long as any platinum chloride remains. It seems important that throughout this stage the bottle should be somewhat tightly corked in order to prevent too rapid formation of platinum black, and its consequent precipitation in the fluid. If the platinum chloride appears to be exhausted before the tissue is sufficiently blackened, more may be added. When ready for examination the piece of tissue is placed in dextrin solution for several hours, and then cut into thin sections with the aid of the freezing microtome. These are dehydrated, cleared, and mounted in balsam in the usual way. He has, so far, seen no injury of the preparations from the use of a cover glass. The deposit which forms is evidently what is known as "platinum black," a substance which consists either of metallic platinum or of an oxide of this metal. The chemical change in the platinum bichloride seems to be dependent upon the presence in the solution of a certain quantity of formic acid, which is slowly produced by oxidation of the formaldehyde. As he has indicated, the black reaction does not occur in a uniform manner throughout the tissues, but selects first certain special elements. The histological picture produced is one which is entirely different from that obtained by Golgi's sublimate and silver methods and their modifications.

Owing to the long time that is required for the carrying out of the method, the amount of material that he has been able to examine by it up to the present is not very large, and chiefly for this reason he has found it impossible as yet to come to a definite conclusion upon many of the difficult questions suggested by the appearances that the preparations present. But the new view of the structure of the central nervous system that the method is capable of furnishing has seemed to him so full of interest, and in certain respects so important, that he has thought it desirable to publish a short account of the matter without further delay.

The chief structural features, he says, revealed by this method may be grouped under four headings—viz.: (1) The presence of fibres in the walls of the intracerebral and medullary vessels; (2) the primitive fibrils of the protoplasm of the nerve cell; (3) the presence of certain granules in the nucleus of the nerve cell; and (4) the existence of special cell elements in the brain. There are also other minor structural features brought out, upon which, however, he does not propose to touch at present.

Laparotomy for Perforating Ulcer of the Stomach.—M. Hildebrandt (*Tribune med. abt.*, April 12th) recently communicated to the Medical Society of Kiel the case of a man, forty-four years of age, suddenly seized with violent abdominal pains and an association of symp-

* Ell vs. Willour, 49 N. J. L., 685.

⁴ Rosseau vs. Hyers, 52 Wis., 651.

|| Whitwell vs. Hill, 66 N. W. Rep., 894.

toms pointing to a perforating ulcer of the stomach. Medical treatment caused temporary alleviation, but subsequent augmentation ensued and peritonitis supervened. On opening the abdominal cavity, notwithstanding the patient's desperate condition, agglutinated coils of intestine were seen. There was a serofibrinous exudation and also a purulent effusion in the pelvis. On raising the liver the perforation was found at the lesser curvature near the pylorus. Three stitches were inserted. The abdominal cavity was cleaned and packed with sterilized gauze for drainage, two silk sutures being inserted in the abdominal wall. The temperature remained high for ten days and then fell to normal, and the patient was discharged from the hospital two months later.

Largine in the Treatment of Gonorrhœa.—Dr. L. Fürst (*Lassar's dermatologische Zeitschrift*, iv; *Presse médicale*, March 25th) describes largine as a grayish powder easily soluble in water, forming a clear solution which is feebly alkaline and quite stable if kept in colored bottles. It is a silver compound closely allied to protargol. It has all the medicinal properties of protargol and is a more energetic antiseptic. With a 1-to-4,000 solution, Pezzoli, Kornfeld, and Aufrecht have destroyed virulent cultures of the gonococcus in ten minutes. Fürst has employed largine with complete success in the treatment of eleven women affected with endometritis, cervical metritis, inflammation of the vulva, or inflammation of the urethra and bladder. In every case the gonorrhœal nature of the trouble had been demonstrated microscopically. Largine in aqueous solution is employed as an irrigant. It is well to begin with a weak solution, 1 to 200, and increase the strength gradually.

The Early Diagnosis of Epithelioma of the Penis.—Mr. Jonathan Hutchinson, F.R.C.S. (*Lancet*, April 22d), in a clinical lecture recently delivered at the London Hospital, said: "When cancer of the penis is left to itself it kills either by hæmorrhage or by infection of lymphatic glands in the groin. The all-important point is to recognize the cases before the lymphatic glands have become adherent to the vessels, and not to mistake them for cases of primary chancres or tertiary growths, or for warty growths. A careful microscopic examination of the discharge ought to settle this point, and if any doubt still remains, then you should slit up the prepuce. If you carefully do these things it may make a difference of many years of life to your patient."

Gelatin Injections in Hemorrhages.—At a recent meeting of the Lancian Society of the Hospitals of Rome (*Riforma medica*, March 28th) Dr. U. Arcangeli reported that he had used this treatment with complete success in two cases of purpura hæmorrhagica. He described the technics as most simple. The gelatin employed was of the variety known to bacteriologists as "gold-marked" [*marca d'oro*]. The solution was sterilized over a water bath, and had to be warmed at the time of its employment, the preparation being solid at ordinary temperatures. The injections were thrown into the subcutaneous tissue of the abdominal wall. This treatment, the speaker thought, could be employed with confidence in scurvy, purpura, hæmoptysis, the intestinal hæmorrhage of typhoid fever, hæmatemesis, the epistaxis and other hæmorrhages of malarial cachexia, and the hæmorrhages of pernicious anaemia. It was contraindicated by actual endocarditis and by alterations of the cerebral arteries.

The Composition of Chartreuse.—The *Revue médicale* for April 19th, citing the *France médicale*, gives a summary of the facts from an article by the Vicomte d'Avenel in the *Revue des deux mondes* relating to the composition of chartreuse. More than forty plants enter into its composition. The principal one is balm (*Melissa officinalis*), of which from two hundred and fifty to five hundred grammes are present in a hundred litres; hyssop in flower, peppermint, Alpine génepi (*Artemisia glacialis*), the seeds and roots of angelica, of each from a hundred and twenty-five to two hundred and fifty grammes; then in smaller quantities, varying from fifteen to thirty grammes, arnica flowers, thyme, balsamite, the buds of the poplar balsam (*Populus balsamea*), Chinese cinnamon, mace, coriander, aloes, cardamoms, etc. Moreover, each hundred litres contains an alcoholate in which are present with "majolaine," clove pinks, and lavender, four kinds of pepper (long, Jamaica, cubeb, and culinary), pine resin, treacle, hyacinth, balsam of nutmeg, kneaded together in Malaga wine. A hundred litres of the liqueur contain about twenty-six hundred grammes of this mixture, and the cost of preparation scarcely exceeds eight francs (about \$1.60). The quality and age of the alcohol used in the manufacture are the principal feature. The medicinal properties of chartreuse as a stomachic, antidyseptic, and carminative are well known, but truly it is a "bird-shot" prescription. Its popularity, however, doubtless depends on its palatableness rather than on its medicinal properties.

Gelsemium in Grippe.—According to the *Medical Monograph* for April, Dr. Barry, of Mexico, suggests the administration in grippe of five-drop doses of tincture of gelsemium every hour till the physiological effect is reached, which should be maintained for twenty-four hours. [The physiological effects of gelsemium being of a paralytic character, we imagine that considerable caution is requisite in the use of this prescription, which we are not told that the author has actually used.]

Birth of Fœtus per Vias Naturales in a Case of Extra-uterine Pregnancy.—Malinowski (*Medizinskoje Obolsrenyoe*, 1898; *Obstetries*, April, 1899) reports this case as occurring in a woman, aged thirty-eight years, a multipara. During labor abdominal palpation revealed one tumor, corresponding to the uterus, with a second smaller one, attached to the former and on the right side. Pains becoming inefficient, forceps were applied, but were unsuccessful. Craniotomy was then performed and child removed, but the smaller tumor did not disappear. The operator's hand was then introduced into the empty uterus, and thence to the right Fallopian tube, where the placenta was found and removed. The woman made a good recovery.

Experiments on the Prophylactic Value of Cinchona Preparations issued in Indian Jails.—Captain W. J. Buchanan, I. M. S. (*Journal of Tropical Medicine*, March), thus formulates the conclusions derived from an investigation of jail practice in India:

"It will appear . . . that the opinion of the fifty-one medical officers in India who replied to my queries is on the whole favorable to the prophylactic issue of quinine or cinchonidine. That the results are not more marked is due to many considerations—viz., a somewhat changing population (in small jails with short-term prisoners at least) and local considerations of climate and season. It is also more than probable that the results would have been better marked if

quinine had been given in place of cinchonidine. In India this prophylactic has been tried against the æstivo-autumnal fevers; it has been very little tried in cases of spring fevers; indeed, in my experience the fevers we get in the plains of northern India in the dry hot months are not malarial but due to exposure, heat, sun, etc. I have certainly found the hæmatozoa much less frequently in the spring months than in the rainy season, from August to the end of October. Personally the result of my three years' experience of this prophylactic on a large scale (not less than twelve hundred prisoners daily) is to make me enthusiastically in favor of it, and I believe the more thoroughly it is carried out the greater will be the benefit to the persons taking it. In the ensuing season I shall try the effects of still larger doses."

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of February 1, 1899.

The President, Dr. S. ALEXANDER, in the Chair.

Ligation of the Subclavian Artery.—Dr. JOHN F. ERDMANN presented a patient in whom he had successfully ligated the third portion of the subclavian artery for aneurysmal varix following a gunshot wound.

Report of a Case of Removal of the Gasserian Ganglion, with the Second and Third Divisions of the Fifth Nerve; Hartley-Krause Operation.—Dr. ERDMANN reported the case. (See page 621.)

Dr. JOSEPH COLLINS said that the paper was of more than usual interest, in view of the very satisfactory results that had attended an operation concerning the advisability of which there was by no means a feeling of unanimity in the profession. The impotency of drugs in the successful treatment of true tic douloureux was a painful reflection on therapeutics. We heard of tic douloureux being treated successfully by this drug and by that, but those who had the modern conception of the disease knew that the cases reported cured were symptomatic trifacial neuralgia and not genuine tic douloureux. The latter was not only a degenerative nervous disease, but occasionally a nervous disease of degeneracy. The treatment that was demanded for its relief must be more searching than mere relief of the pain. The entire organism must be fortified, the nutritive fluids stimulated to do their work, and, at the same time, the local parts the seat of the disease subjected to the application of measures which would help to maintain local nutrition. These ends could best be attained, according to his experience, by adopting the plan of treatment suggested some years ago by Dr. Dana, which consisted in the administration of strychnine, hypodermically, in doses of from one sixteenth to one fortieth of a grain, and iodide of potassium, in doses of from seven to twenty grains, depending upon the changes in the blood vessels, while the patient was made to remain in bed and put through a modified rest cure. This plan of treatment, the speaker said, had served him satisfactorily when all other plans of medication had failed. That it was not infallible for tic douloureux might be readily inferred.

Latterly he had been in the habit of combining the strychnine with small doses of morphine, and with, it seemed to him, more satisfactory results than when the strychnine alone was given. He did not believe that the strychnine had any specific effect. It contributed to restoration of neural equilibrium, and acted as an efficient helper to the alteratives, tonics, and nutritional measures that were simultaneously adopted. Every case of inveterate tic douloureux should be subjected to this plan of treatment, and thoroughly, before the question of undertaking such a hazardous operation as extirpation of the Gasserian ganglion was discussed. One might not infer, from listening to the paper of the evening, that this was an operation fraught with great peril to him who decided to accept it in the hope that it might either assuage his suffering or result in death; but, as a matter of fact, it was not at all unlikely that the mortality was from thirty to forty per cent., although the most reliable statistics made it only about twenty-two per cent. Before undertaking an operation that was attended with such mortality as this for the relief of a disease that did not lead to death, save by the hand of the sufferer, the surgeon should have convinced himself that every other way of treating it with any degree of success had failed. He should not delude himself that he was justified in performing it because the patient, after having been apprised of its danger, had willingly consented. Sufferers from tic douloureux would consent to almost anything on account of the absolute unendurableness of the pain. But the surgeon owed a duty to himself as well as to the patient, and this duty required that every other means of treating the disease should be exhausted before it was subjected to operation. It was encouraging to find that those who had most experience with the operation were maintaining that the mortality rate was in definite relationship to the technics, and as the latter was improved the mortality rate would be lowered. From his limited experience in having these patients operated on, it had seemed to him that it was advisable at the present time to have the operation done in two sittings. The fact that destruction of the cornea occurred so late seemed to be against the existence of special trophic nerves.

Dr. QUIMBY said he could not let Dr. Collins make such logical statements and then close with such an illogical one as that there could be no trophic nerve in the Gasserian ganglion. No conclusion could be logically drawn from a single case.

The President said he would like to ask Dr. Collins the result of the large doses of strychnine. He had not operated in these cases, but had noticed cases treated with medicines with but little beneficial results.

Dr. COLLINS said he had seen two cases treated with morphine and strychnine last autumn, both in old persons, and there had been no return of the trouble. He had seen a woman treated in the same manner with recovery. She had afterward sustained the shock of the loss of her husband, and had not relapsed.

The administration of strychnine alone was not to be advised, for there were none of the cases that did not show arteriosclerosis. He fully believed that this treatment would be found the most advisable. In response to Dr. Quimby he wished to say that he still held there was no trophic nerve in the Gasserian ganglion, but did not hold that there were no sympathetic nerves.

The President asked Dr. Collins how much of the favorable results was attributable to the strychnine and how much to the morphine.

Dr. COLLINS said that in the first published cases no morphine had been given. He thought the beneficial action was due to the strychnine in its regenerative effect upon the nerves. Iodide of potassium perhaps acted in the same way. He thought that the morphine only tended to assuage the pain, to carry the patient on for a time. One sixth of a grain was as much as was administered. He thought the good effects were due to the rest, the strychnine, and the alleviating of the pain with the morphine.

Dr. PARKER SYMS asked Dr. Erdmann if he thought the destruction of the cornea after the man returned to his home had been due to trauma.

Dr. ERDMANN said the man had returned to his home, was about attending to his business on the farm, and had reported to his physician, after six or seven weeks had elapsed, that his sight was becoming defective on the side of the operation. In all probability the ulceration was due to some injury by dust.

In regard to the mortality, it seemed to vary with the method of operation. The early statistics embraced operations by different methods, while those he had given were those of the Hartley-Krause method only.

(To be concluded.)

Book Notices.

General Physiology: An Outline of the Science of Life.

By MAX VERWORN, M. D., Ph. D., A. O. Professor of Physiology in the Medical Faculty of the University of Jena. Translated from the Second German Edition and edited by FREDERIC S. LEE, Ph. D., Adjunct Professor of Physiology in Columbia University. With Two Hundred and Eighty-five Illustrations. New York: The Macmillan Company, 1899. Pp. xvi-615. [Price, \$4.]

THIS work is a translation of the second German edition, and is described on the title-page as "an outline of the science of life." The book has been very generally read in the German scientific world, and it may be read to advantage by any one seeking scientific information regarding the phenomena of life. Its general purpose is to trace back to the individual cells the source of activities in life. Thus, the respiration and the circulation of the blood are not elementary phenomena, but are the consequence of the contraction of the respiratory muscles or of the heart muscles. In these muscles the activity is due to the power which the muscle cells possess of changing their form, of becoming shorter and thicker. This power is not derived from nothing, but from energy developed through chemical changes within the cells in strict accordance with the universal law of the conservation of energy.

The book defines an organic individual as "a unitary mass of living substance which under definite external vital conditions is capable of self-preservation." These individuals are represented as consisting of five orders of increasing complexity: 1. Single cells, unicellular organisms. 2. Tissues, consisting of cells, like certain algae. 3. Organs, consisting of tissues, like the hydra. 4. Persons, made up of organs, like man. 5. Communities made up of persons, like communities of ants and bees. Through such a scheme the possibility of development along the lines of evolution is made clear.

Biological relations between different kinds of cells and living things are constantly kept in view throughout the book.

The general historical review and the chapter on suspended animation will be found interesting. The theories of development are fully discussed. The book contains two hundred and eighty-five excellent illustrations.

Some of the repetition of the original German has been eliminated in this translation, although some, perhaps necessarily, has been retained. In spite of the fact that the book would be stronger if it could be more condensed, it remains a very instructive treatise upon general physiology, considered from a standpoint not usually so fully emphasized. In this more novel treatment lie its charm and value, and medical and scientific men generally may well be grateful to Dr. Lee for his excellent translation.

Elementary Physiology. By BENJAMIN MOORE, M. A., Professor of Physiology in the Medical Department of Yale University, etc. With One Hundred and Twenty-five Illustrations. New York, London, and Bombay: Longmans, Green, & Co., 1899. Pp. vi-295.

PROFESSOR MOORE'S book, while emphasizing perhaps too strongly the anatomical details of the subject, is still an excellent one for its purpose. Though it has been written with as little of the usual technical language as possible, technical names are used throughout. It is thus of value to the junior student, and at the same time not too cumbersome for the reader whose interest is only a general one. The figures with which the text is fully illustrated are well chosen and clear, and in every case remarkably well reproduced.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Volume I. March, 1899. Surgery of the Head, Neck, and Chest—Diseases of Children—Pathology—Infectious Diseases, including Croupous Pneumonia—Laryngology and Rhinology—Otolaryngology. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. viii-17 to 490.

WE are told in the preface of this volume that "there are at the present time numerous 'annuals,' or 'year-books,' published with the object of recording in condensed form the greater part of the medical literature of the year, but in nearly all of them the process of 'boiling down' has been practised without first sifting the useful from the useless." This statement is in a measure true, but the inference from what follows is to the intent that the volume before us will be a departure from the practice its editor criticises. We are of the opinion that the material contained in this volume has been well selected and ably made use of, but not more so, we think, than is the case in more than one of the excellent annuals now upon the market. In fact, with the exception of certain peculiar advantages of arrangement, it is difficult to see wherein lies the implied superiority of this work as compared with others of the "annual" class. We do not mean to be carping, for indeed we think the work an able and an excellent one; it is only to the assumption of non-apparent and exceptional superiority to which we take exception.

The volume is devoted to the more recent advances and discoveries in the surgery of the head, neck, and chest; the diseases of childhood; pathology; infectious diseases; and laryngology, rhinology, and otology. It is well written and by men whose right to authoritative utterance is unquestioned; it is well edited, and it is exceedingly well published. The division of the work into volumes of convenient size is much to its advantage.

Manual of Clinical Chemistry. By ELIAS H. BARTLEY, B.S., M.D., Ph.G., Professor of Chemistry and Toxicology in the Long Island College Hospital, etc. Thirty-three Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. vi-9 to 150. [Price, \$1.]

THE announcement appearing in the preface of this book that "in this small volume will be found the essentials of chemical diagnosis, or a description of all those chemical processes most useful to the practising physician," is sufficient to describe the scope of the work. It is composed in greater part of the final chapters of the *Text-book of Medical and Pharmaceutical Chemistry* by the same author, and of that work we have already expressed a favorable opinion. To these chapters some material has been added which chiefly concerns food examination and uranalysis. The convenience of having a small volume dealing aptly with chemical diagnosis is self-evident.

Glaucoma: its Symptoms, Varieties, Pathology, and Treatment. By ALEXANDER W. STIRLING, M.D., C.M. (Edin.), D.P.H. (Lond.), Late House Surgeon, Royal Westminster Ophthalmic Hospital, etc. With Illustrations from Microphotographs. St. Louis: Jones H. Parker, 1899. Pp. viii-177.

THIS is a monograph based upon the author's lectures before the students of the Post-graduate Medical School. They have been published serially in the *Annals of Ophthalmology*, and are here reproduced in one volume. The book is a very complete *résumé* of the subject up to the present time. It is divided into fifteen chapters and nearly half of them are devoted to a consideration of the aetiology of the disease. All the theories which have been held as to the causation of glaucoma are fully considered, but it may be thought that too much space has been given to views which have long since been exploded. Three chapters are devoted to a description of the varieties of glaucoma, and three more to treatment. In the latter much stress is laid on the necessity of tearing the iris from its peripheral insertion rather than making an iridectomy by cutting the iris with the scissors. There is a good index and there is an excellent list of biographical references.

A Practical Handbook on the Muscular Anomalies of the Eye. By HOWARD F. HANSELL, A.M., M.D., Clinical Professor of Ophthalmology, Jefferson Medical College, etc., and WENDELL KERR, M.D., Instructor in Ophthalmology, Philadelphia Polytechnic and College for Graduates in Medicine, etc. Twenty-eight Illustrations and One Plate. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. 9 to 187. [Price, \$1.50.]

THIS is a book intended for beginners in ophthalmic work. It is divided into four parts. The first, or an

introductory, part treats of the anatomy and physiology of the external muscles of the eye. The second part is devoted to a consideration of the paralyses of the various ocular muscles, their aetiology, symptomatology, and treatment. The third and most important part takes up the functional anomalies or the various forms of heterophoria, their general diagnosis, the different tests for detecting their presence, and a general consideration of musculo-dynamics. The fourth part is devoted to a description of the operations on the muscles. In the operation for advancement the authors advocate making a conjunctival flap over the course of the muscle, followed by a similar flap of the subconjunctival tissue and capsule of Tenon, so as to give a roomy field for operation, the flap being turned upward and held out of the way by an assistant. The method of introducing the sutures for the purpose of advancement may fairly be the subject of criticism.

There is an excellent index.

Annual and Analytical Cyclopædia of Practical Medicine. By CHARLES E. DE M. SAJOURS, M.D., and One Hundred Associate Editors, Assisted by Corresponding Editors, Collaborators, and Correspondents. Illustrated with Chromolithographs, Engravings, and Maps. Volume III. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. vii-600.

THE third volume of this great work carries the vocabulary from Dislocations to Infantile Myxœdema. It is clear that the members of Dr. Sajours' editorial staff continue in their devotion to the undertaking in a degree seldom exemplified in so large and comprehensive a literary work. But it is equally clear that Dr. Sajours himself preserves his initial enthusiasm and masterly supervision. This cyclopædia, we have no hesitation in saying, is one of the most indispensable of medical reference books.

Diet in Illness and Convalescence. By ALICE WORTHINGTON WINTHROP. Profusely Illustrated. New York and London: Harper & Brothers, 1899. Pp. vii-3 to 287.

THE plan on which this book has been prepared is most excellent, for it endeavors first to present the rationale of diet and, in the second place, to give practical instruction in cookery. As a cook-book adapted to the requirements of invalidism too much can not be said in its favor; as a medical or a semi-medical treatise it is very inferior.

The composition of food elements and the physiology of feeding are first very briefly stated, and then digestion is described. Digestion naturally leads up to artificial digestion, the subject that is next discussed. Several chapters that are devoted to the various beverages and foods that are in common use come next, and then there is a brief chapter upon diet for infants. The semi-medical portion of the book is concluded by a description of the diets appropriate in various states of disease. Now, these first chapters, indeed, contain much that is proper and useful, and they are well written, but they are unfortunate in that they are often in error. It is, indeed, a difficult task to decide the mysteries of physiology and of pathology to the uninitiated, and one that requires the skill not only of a teacher, but of an expert. It is unfortunate that the first portion of the

book could not have been omitted, for of the second only praise can be expressed. In it there are given most useful and excellent directions for preparing and serving the food of invalids, and recipes to a very great number are presented. A feature that is useful, too, is the illustration of this part of the book. Indeed, for those who either directly or indirectly are called upon to cater to the sick these chapters can not but be of much assistance, and how important a branch of medicine it is properly to select and prepare and serve the food is perhaps not always appreciated.

BOOKS, ETC., RECEIVED.

Annual and Analytical Cyclopedia of Practical Medicine. By Charles E. de M. Sajous, M.D., and One Hundred Associate Editors; assisted by Corresponding Editors, Collaborators, and Correspondents. Illustrated with Chromolithographs, Engravings, and Maps. Volume III. Dislocations to Infantile Myxœdema. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. vii-600.

Chemistry: General, Medical, and Pharmaceutical, including the Chemistry of the United States Pharmacopœia. A Manual on the Science of Chemistry, and its Application in Medicine and Pharmacy. By John Attfield, F.R.S., Ph.D. of the University of Tübingen, F.I.C., F.C.S., for Thirty-four Years Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, etc. Sixteenth Edition. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. xxii-17 to 780.

Clinical Lectures delivered before the Students of the Imperial Moscow University. By G. A. Zacharin, M.D., Late Professor (Emeritus) of Clinical Medicine and Director of the Therapeutical Faculty Clinic of the Imperial Moscow University, etc. Translated from the Fifth Russian Edition by Alexander Rovinsky, M.D., Member of the Massachusetts Medical Society. Boston: Damrell & Upham, 1899. Pp. xvi-187.

A Manual of Organic Materia Medica. Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the Use of Students, Druggists, Pharmacists, and Physicians. By John M. Maisch, Ph.D., Phar. D., Late Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. Seventh Edition. Revised by Henry C. C. Maisch, Ph.D., Ph.D., Professor of Materia Medica and Botany in the Medicoburgical College of Philadelphia, Department of Pharmacy. With Two Hundred and Eighty-five Illustrations. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. vi-17 to 523.

The Philosophy of Memory and Other Essays. Consisting of Articles on the Philosophy of Emphasis: The Functions of the Fluid Wedge; the Birth of a Planet; the Laws of Riverflow. By D. T. Smith, M.D., Lecturer on Medical Jurisprudence in the University of Louisville. Louisville: John P. Morton & Company, 1899. Pp. 9 to 263.

The Principles of Bacteriology: A Practical Manual for Students and Physicians. By A. C. Abbott, M.D., Professor of Hygiene and Director of the Laboratory of Hygiene, University of Pennsylvania. Fifth Edition, enlarged and thoroughly revised. With One Hundred and Nine Illustrations, of which Twenty-six are Colored. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. xi 17 to 590.

The International Medical Annual and Practitioner's Index: A Work of Reference for Medical Prac-

tioners. By Various Contributors. Seventeenth Year. New York: E. B. Treat & Co., 1899. Pp. 758.

Syphilis. Von Dr. Isidor Neumann, o. ö. Professor der Dermatologie und Syphilis an der Universität Wien. Zweite Auflage. Mit 60 Abbildungen. Wien: Alfred Hölder, 1899. Pp. xv-852.

Die Krankheiten der Mundhöhle, des Rachens und des Kehlkopfes. Mit Einschluss der Untersuchungs- und Behandlungsmethoden. Für praktische Aerzte und Studierende. Von Dr. Albert Rosenberg, in Berlin. Zweite neu durchgesehene und erweiterte Auflage. Mit 180 Abbildungen im Text. Berlin: S. Karger, 1899. Pp. x-2 to 412.

Die multiple Fettgewebnecrose. Klinische und experimentelle Studien. Von Dr. Arthur Katz und Dr. Ferdinand Winkler, Assistenten an der allgemeinen Poliklinik in Wien. Mit 15 Abbildungen. Mit einem Vorwort von Dr. Leopold Oser. Berlin: S. Karger, 1899. Pp. 139.

The One Hundred and Ninth Annual Report of the Board of Trustees of the New York Dispensary. For the Year 1898.

Third Annual Report of the State Board of Medical Registration and Examination of Ohio. 1898.

Gallstones and Abscess of Liver. By W. Louis Hartman, M.D., of Syracuse, N.Y. [Reprinted from the *Hahemannian Monthly*.]

A Case of Abnormally High Temperature subsequent to an Attack of Tertian Ague. By S. Grainger, M.D. [Reprinted from the *Canadian Journal of Medicine and Surgery*.]

Some Observations on the Traumatic Neuroses in Relation to Litigation. By Samuel Ayres, M.D., of Pittsburgh. [Reprinted from the *Pennsylvania Medical Journal*.]

Surgery of the Kidney: Being a Study of a Series of Cases in which Methods of Diagnosis and Treatment are Illustrated. By Bayard Holmes, M.D., of Chicago. [Reprinted from the *Journal of the American Medical Association*.]

Growing Children: Their Clothes—and Deformity. By E. Noble Smith, F.R.C.S. Edin., L.R.C.P. Lond., etc.

Vitality: An Appeal, an Apology, and a Challenge. By Lionel S. Beale, of London. [Reprinted from the *Lancet*.]

Some Unlooked-for Occurrences in the Practice of Medicine. By Robert E. Coughlin, M.D., of Brooklyn. [Reprinted from the *Brooklyn Medical Journal*.]

The Bearing of the Neurotrophic Function on Cutaneous Conditions. By Samuel Wolfe, M.D., of Philadelphia. [Reprinted from the *Philadelphia Medical Journal*.]

Remedial Measures Proposed for Pennsylvania. By Samuel Wolfe, M.D. [Reprinted from the *Transactions of the Twenty-fifth National Conference of Charities and Correction*.]

A New Hearing Device. By Emil Amberg, M.D., of Detroit. [Reprinted from the *Physician and Surgeon*.]

The Serum Treatment of Streptococcal Infection. A Report of Five Cases. By E. W. Saunders, M.D., of St. Louis. [Reprinted from the *American Journal of Obstetrics*.]

Zur Histologie der Milchdrüse. Von Anton Slicker, Dr. med. [Sonderabdruck aus dem *Archiv für mikroskopische Anatomie und Entwicklungsgeschichte*.]

Practical Materia Medica for Nurses. With an Appendix containing Poisons and their Antidotes, with

Poison Emergencies; Mineral Waters; Weights and Measures; Dose List; and a Glossary of the Terms used in Materia Medica and Therapeutics. By Emily A. M. Stoney, Late Superintendent of the Training School for Nurses, Carney Hospital, South Boston, Massachusetts, etc. Philadelphia: W. B. Saunders, 1899. Pp. 5 to 306. [Price, \$1.50.]

The Anatomy of the Central Nervous System of Man and of Vertebrates in General. By Professor Ludwig Edinger, M. D., Frankfurt-on-the-Main. Translated from the Fifth German Edition by Winfield S. Hall, Ph. D., M. D., Professor of Physiology in the Northwestern University Medical School, Chicago. Assisted by Philo Leon Holland, M. D., Instructor in Clinical Neurology in the Northwestern University Medical School, Chicago; and Edward P. Carlton, B.S., Demonstrator of Histologic Neurology in the Northwestern University Medical School, Chicago. Illustrated with Two Hundred and Fifty-eight Engravings. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. xi-446.

An Epitome of the History of Medicine. By Roswell Park, A. M., M. D., Professor of Surgery in the Medical Department of the University of Buffalo, etc. Based upon a Course of Lectures delivered in the University of Buffalo. Second Edition. Illustrated with Portraits and other Engravings. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. xiv-370.

Urinary Analysis and Diagnosis by Microscopical and Chemical Examination. By Louis Heitzmann, M. D. With One Hundred and Eight Original Illustrations. New York: William Wood & Company, 1899. Pp. xvii-253.

Atlas of the External Diseases of the Eye; including a Brief Treatise on the Pathology and Treatment. By Professor Dr. O. Haab, of Zürich. Authorized Translation from the German. Edited by G. E. de Schweinitz, A. M., M. D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, etc. With Seventy-six Colored Plates and Six Engravings. Philadelphia: W. B. Saunders, 1899. Pp. 7 to 228.

A Characteristic Materia Medica presented in Reverse Order. By Nicholas Bray, M. D. Dubuque, Iowa: Telegraph Job Print, 1897. Pp. 10 to 705.

Annuaire des eaux minérales, stations climatiques et sanatoria de la France et de l'étranger. Suivi d'une nomenclature des établissements hydrothérapiques. Par le Docteur G. Morice, vice-président de la Société d'hydrologie médicale de Paris, etc. Quarante et unième année, 1899. Paris: Librairie Maloine. Pp. 5 to 287.

Veröffentlichungen aus dem Gebiete des Militär-Sanitätswesens. Herausgegeben von der Medizinal-Abtheilung des königlich preussischen Kriegsministeriums. Heft 13. Kriegschirurgen und Feldärzte des 17. und 18. Jahrhunderts. Von Professor Dr. Albert Köhler, Oberstabsarzt I. Cl. Mit 13 Portraits, 5 Abbildungen, und 2 Plänen. Berlin: August Hirschwald, 1899. Pp. x-269.

Beiträge zur Augenheilkunde in Gemeinschaft mit Professor Dr. E. Fuchs, in Wien; Professor Dr. O. Haab, in Zürich; Professor Dr. A. Vossius, in Gießen. Herausgegeben von Professor Dr. R. Deutschnann, in Hamburg. Heft 31-40. Hamburg und Leipzig: Leopold Voss, 1899.

Anthropological Investigations on One Thousand White and Colored Children of Both Sexes; the inmates of the New York Juvenile Asylum; with Addi-

tional Notes on One Hundred Colored Children of the New York Colored Orphan Asylum. By Dr. Ales Hrdlicka.

Annual Reports of the Bureau of Health of the City of Denver. For the Years 1897 and 1898.

Transactions of the Berks County Medical Society. For the Year ending December 31, 1898.

The Bête Noire of the Vocalist. By Edwin Pynchon, M. D., of Chicago. [Reprinted from the *Alkaloidal Clinic*.]

The Absolute and Permanent Cure of Tonsillitis. By Edwin Pynchon, M. D. [Reprinted from the *Alkaloidal Clinic*.]

A Lecture on the Causes and Treatment of Harelip. By Francis J. Shepherd, M. D., of Montreal. [Reprinted from the *Montreal Medical Journal*.]

On So-called Functional Heart Murmurs. By Maude E. Abbott, M. D., of Montreal. [Reprinted from the *Montreal Medical Journal*.]

A Series of Nine Abdominal Pan-hysterectomies performed in One Year for Uterine Fibromyoma. By F. A. L. Lockhart, M. B., of Montreal. [Reprinted from the *Montreal Medical Journal*.]

Chirurgische Krankheiten an Kopf, Hals und Brust. Bearbeitet von Professor Dr. A. Köhler. [Separat-Abdruck aus *Virchow's Jahresbericht der gesammten Medicin*.]

Miscellany.

The Society of the Alumni of the Sloane Maternity Hospital.—At the annual dinner, held in the New York Athletic Club on April 28th, the following officers were elected: President, Dr. George L. Broadhead; vice-presidents, Dr. A. Ernest Gallant and Dr. Eugene Coleman Savidge; recording secretary, Dr. James D. Voorhes;

corresponding secretary, Dr. Frank R. Oastler; treasurer, Dr. Edwin Sternberger; pathologist, Dr. James Ewing; members of the council, Dr. James J. Philips, Dr. William S. Stone, and Dr. Edward W. Peet.

American Climatological Association.—The sixteenth annual meeting will be held in New York on Tuesday, Wednesday, and Thursday, May 9th, 10th, and 11th, under the presidency of Dr. Beverley Robinson. The programme contains the following titles: Address by the president: The Ideal Physician—his Character and Attainments; The Treatment of Consumption by Air and Light in Colorado: Air as a Cure; Ranching; Tent Life compared with House Life; Effect of Light, by Dr. Charles Fox Gardiner, of Colorado Springs; Suggestions concerning Early Diagnosis in Pulmonary Tuberculosis, by Dr. Sherman G. Bouney, of Denver; Notes on the Tuberculin Test, by Dr. E. O. Otis, of Boston; Subsequent Histories of "Arrested Cases" of Phthisis treated at the Sharon Sanitarium, by Dr. Vincent Y. Bowditch, of Boston; Röntgen-ray Examinations in Lucipent Pulmonary Tuberculosis, by Dr. Francis H. Williams, of Boston; The Intermediate Altitude for the Consumptive, by Dr. B. P. Anderson, of Colorado Springs; The Contagiousness of Phthisis Pulmonalis, by Dr. E. L. Shurly, of Detroit; Why Fumigation of Apartments occupied by Tuberculous Patients at Health Resorts should be under Municipal Control, by Dr. Charles F. McGahan, of Aiken, South Carolina; The Climate of the East Coast of Florida, by Dr. Frank Fremont Smith, of Palm Beach, Florida; Climate in Relation to Renal Disease, by Dr. J. B. Walker, of Philadelphia; Climate as it Affects the Skin and its Diseases, by Dr. L. D. Bulkley; Hygienics of the Skin, by Dr. L. D. Judd, of Philadelphia; Hydrotherapy in the Treatment of Insomnia, by Dr. Irwin H. Hance, of Lakewood, N. J.; The Climatology of Nudity, by Dr. W. D. Robinson, of Philadelphia; Recent Inquiries concerning the Blood Changes Induced by Altitude, by Dr. S. E. Solly, of Colorado Springs; Altitude and Heart Disease, with a Report of Cases, by Dr. Robert H. Babcock, of Chicago; Functional Cardiac Murmurs, by Dr. A. Jacobi, of New York; The Prognosis in Chronic Valvular Affections of the Heart, by Dr. N. S. Davis, Jr., of Chicago; The Treatment of the Cardiac Asthenia of Pneumonia, by Dr. H. L. Elsner, of Syracuse, N. Y.; Remarks based on a Further Experience with Calomel in Diphtheria, by Dr. L. D. Judd, of Philadelphia; Esophageal Suction as a Cause of a Simulated Heart Murmur, by Dr. Roland G. Curtin, of Philadelphia; A Note on Exercises Suitable for Children with Heart Troubles, by Dr. John Madison Taylor, of Philadelphia; Embolism, by Dr. William M. Gibson, of Utica, N. Y.; Empyema from a Surgical Standpoint, by Dr. John C. Munro, of Boston; Traumatic Rupture of the Heart without Penetration of the Chest Wall, by Dr. Richard C. Newton, of Montclair, N. J.; Bicycling in its Relation to Heart Disease, by Dr. A. C. Getchell, of Worcester, Massachusetts; The Effect of Violent and Prolonged Muscular Exercise upon the Heart, by Dr. Harold Williams, of Boston; The Relation of Local Meteorologic Conditions to the Influenza Epidemic in Philadelphia in the Winter of 1898-'99, by Dr. Howard S. Anders, of Philadelphia; and The Cold Wave of February, 1899, by Dr. Guy Hinsdale, of Philadelphia.

Idiopathic Dilatation of the Colon.—At the fourteenth annual meeting of the Association of American

Physicians, held in Washington this week, Dr. J. P. Crozer Griffith, of Philadelphia, presented a paper in which he said that dilatation of the colon might depend upon several causes. First, there might be an acquired dilatation, oftentimes the result of chronic constipation. Second, there might be a congenital dilatation dependent upon some form of stenosis. Third, there might be a congenital idiopathic dilatation—*i. e.*, not dependent upon any discoverable organic cause. Since there was considerable difference among writers regarding the selection of reported cases of idiopathic dilatation, the author had reviewed all the public cases so far as they were known to him, and he gave a synopsis of them in brief, putting in this list, however, only those which it seemed reasonable to regard as belonging to the category of congenital idiopathic dilatation. In a secondary list he mentioned briefly other cases which ought to be excluded, and gave the reasons for this exclusion. He reported in detail a case which had come under his own observation. Analyzing the symptoms of this case and of the cases of the first list mentioned, he reviewed the symptomatology, diagnosis, and treatment of the disease.

Dr. R. H. Fitz, of Boston, presented a paper on the relation of idiopathic dilatation of the colon to phantom tumor, and reported a series of cases for the purpose of suggesting the organic relation of certain cases of phantom tumors and of advocating resection of the sigmoid flexure as a desirable method of treatment of such tumors.

The Immediate and Remote Effects of Athletics on the Heart.—This was the subject of a paper read at the same meeting by Dr. Alfred Stengel, of Philadelphia. Athletics, he said, habitually caused some dilatation of the cardiac chambers at the time of indulgence in a trying sport. The degree of dilatation was more marked in the young and inexperienced than in those who were well trained. Occasionally, acute dilatation, sufficient to cause marked symptoms, was observed. Under these circumstances, a trained athlete might recover compensation within a few days. The effect of continued indulgence in severe sports was the development of some cardiac hypertrophy, and persons who had thus enlarged their hearts frequently suffered symptoms of overcompensation, at least during some years after they had ceased to follow athletics.

Kernig's Sign in Meningitis.—At the same meeting Dr. J. B. Herrick, of Chicago, read a paper in which he said that personal observations showed the sign to be so commonly present in meningitis that, though occasionally absent in this disease and occasionally found in other affections, it was a valuable diagnostic aid.

A Case of Periodic Family Paralysis.—At the same meeting Dr. John K. Mitchell, of Philadelphia, presented a study of the case of a boy of eighteen who had, at frequent but varying intervals, an attack of paralysis. He went to bed well but woke in the morning helpless, paralyzed from head to foot, with total abolition of skin, muscle, and tendon reflexes, loss of faradaic and galvanic contractility, unchanged sensibility, and unimpaired mind and speech. The attacks were hereditary in his mother's family, in which five cases were known. One of these had been seen by the author and the others were described. Careful studies of the electrical conditions and of the urine, the faeces, and the blood, with

attempts to determine their toxic effects, were given. The conclusion was that more than one kind of toxic material was produced, with selective actions on the skin nerves and on the spinal centres. The author added that only three other undoubted cases of like kind had been recorded in America and about sixteen in Europe.

A Case of Fatal Epistaxis, with a Study of the Blood, was the title of a paper presented at the same meeting by Dr. George Dock, of Ann Arbor. The patient was admitted into a hospital for epistaxis which had existed for six weeks. Local examination failed to reveal the cause of the hemorrhage. Notwithstanding treatment with plugging, etc., copious and repeated hemorrhages occurred in the hospital. The patient having been referred to the medical clinic for examination of the blood, conditions were found which did not explain the severe epistaxis, though the changes in the blood, if primary, might have accounted for hemorrhages, such as occurred later, in the retina, etc. There was a great diminution in the number of red blood-corpuscles, ultimately reaching 360,000 in a cubic millimetre. Nucleated red corpuscles were present in large numbers, and included all nucleated kinds, varying in proportion at different times. There was also moderate leucocytosis, and there were great alterations in the proportion to the various forms of the leucocytes. Post-mortem, a small endothelioma of the nasal septum was found, which had caused hemorrhages from both sides. Microscopic metastatic foci were found in various internal organs. Changes in the bone marrow were not marked.

Thyroid Extract in the Treatment of a Cerebral Case.—At the same meeting Dr. Starling Loving, of Columbus, related the case of a student, eighteen years old, of healthy parentage, whose history, with the exception of an attack of typhoid fever in his fifteenth year, had been uneventful. His habits were correct. In 1896, without assignable cause, he began to suffer from constant headache with severe exacerbations. Within six months he found his vision affected, soon to such an extent as obliged him to suspend his studies, and, later, to interfere materially with movement from place to place. Examination by competent oculists disclosed no lesion in either eye, though the vision was about equally affected in both. At a consultation between the oculists, a neurologist, and a surgeon, it was decided that the patient was suffering from an intracranial neoplasm, the nature and precise situation of which were not defined. There was a suspicion of its being of syphilitic origin. The lad was treated with mercurials and iodide of potassium with no beneficial result. After a rest of some weeks treatment was resumed, but it was futile. Tonics were used, but they did no good. Thyroid extract was prescribed, and its use was continued with a few short intermissions for several months. Improvement soon became manifest. The patient had now so far recovered as to be able to read and write with ease and comfort.

Perforation of the Stomach by a Foreign Body in an Infant Seven Weeks Old.—At the same meeting Dr. T. M. Rotch, of Boston, related the case of a male infant seven weeks old who was attacked suddenly with abdominal pain and vomiting. Symptoms of peritonitis developed and on the fourth day from the onset of the attack laparotomy was performed and the abdominal cavity irrigated. Three days later the infant died. The post-mortem examination showed a minute perforation of the stomach in which was found a small thread.

The Ohio State Medical Society.—The fifty-fourth annual meeting will be held in Springfield, on Wednesday, Thursday, and Friday, May 10th, 11th, and 12th, under the presidency of Dr. N. R. Coleman, of Columbus. In addition to the president's address, the programme contains the following papers: The Differential Diagnosis of Small-pox, by Dr. William Thomas Corlett, of Cleveland; Appendicitis, by Dr. Hugh F. Lorimer, of Fair Haven; How to Deal with the Appendix in Pus Cases, by Dr. William Hamilton, of Columbus; Why does the Surgeon Fail to find the Appendix? by Dr. N. Stone Scott, of Cleveland; When should the Physician Call in the Surgeon in Appendicitis, by Dr. Allen H. Vance, of Springfield; Surgical Appendicitis, by Dr. B. M. Ricketts, of Cincinnati; Fifty-seven Consecutive Abdominal Sections without a Death, with Clinical and Pathological Reports, by Dr. Hunter Robb, of Cleveland; Something about Phagocytes, by Dr. D. N. Kinsman, of Columbus; The Diagnostic Value of the Wint-lich Tracheal Sound, by Dr. C. F. Hoover, of Cleveland; Malingering in Ophthalmological and Aural Examinations, by Dr. W. H. Snyder, of Toledo; Gastric Disorders producing Constipation and Diarrhea, by Dr. John P. Sawyer, of Cleveland; Milk as a Carrier of Infection, by Dr. C. O. Probst, of Columbus; Some Medical Considerations concerning the Sale of the Drug Alcohol, by Dr. R. T. Trimble, of New Vienna; Shall the Manufacturers of Drugs do our Prescribing? by Dr. Daniel Milikin, of Hamilton; What should be the Attitude of the Profession toward Christian Science and other Fads? by Dr. John C. Oliver, of Cincinnati; The Prevention of Infection in and after Labor, by Dr. William H. Taylor, of Cincinnati; The New Economic Position of Woman in its Relation to Health and Vigor, by Dr. Mary J. Finley, of Mansfield; The Advisability of Operating in Private Homes, by Dr. Albert F. McVety, of Toledo; Vertigo, by Dr. Philip Zenner, of Cincinnati; The Regular and Periodic Disinfection of Railway Passenger Coaches and Street Cars, by Dr. Frank Warner, of Columbus; Medical Jurisprudence, with Needed Legislation, by Dr. David O. Brine, of Urbana; Observations on the Surgery of the Neck, based on Clinical and Experimental Evidence, by Dr. G. W. Crile, of Cleveland; The Relations of the General Practitioner and the Specialist, by Dr. P. J. Kline, of Portsmouth; Traumatic Cataract, by Dr. C. F. Clark, of Columbus; The Modern Advances in Therapeutics, by Dr. John V. Shoemaker, of Philadelphia; The Medical and Surgical Lessons of the Late War, by Dr. P. S. Comer, of Cincinnati; How the General Practitioner can Aid in the Advancement of Psychiatry, by Dr. E. G. Carpenter, of Columbus; Indications for the Normal Salt Solution, by Dr. E. W. Mitchell, of Cincinnati; How our Neighbors Practise Medicine, by Dr. John F. Fauster, of Paulding; The Symptomatic Treatment of Consumption, by Dr. B. F. Lybe, of Cincinnati; Digitals and the Heart, by Dr. G. M. Waters, of Columbus; The Laryngeal Manifestations of Typhoid Fever, by Dr. L. R. Lockard, Jr., of Toledo; Erythromelalgia, by Dr. William A. Dickey, of Toledo; The Ocular and Orbital Manifestations of Lesions of the Frontal Sinus, by Dr. Robert Sattler, of Cincinnati; Excessive Myopia: When may we Operate and what we may Expect, by Dr. Andrew Timberman, of Columbus; Some Practical Points in the Diseases of Women, by Dr. William M. Humiston, of Cleveland; Some Unusual Cases of Sarcoma of the Kidney, with a Point in Differential Diagnosis, by Dr. J. F. Baldwin, of Columbus; Essentials for Wound

Healing, by Dr. Charles Graefe, of Sandusky; The Practical Application of the X Rays in Surgery, by Dr. William J. Taylor, of Cincinnati; Cases of Obstruction Radically Treated, by Dr. Thomas C. Martin, of Cleveland; The Methods of Making and Closing Abdominal Incisions, by Dr. C. N. Smith, of Toledo; The Treatment of Fractures of the Patella, by Dr. W. J. Means, of Columbus; Edema and Elephantiasis of the External Genitalia following Removal of the Inguinal Glands, by Dr. C. A. Hamann, of Cleveland; and The Iris in the Operation of Cataract Extraction, by Dr. J. E. Brown, of Columbus.

An American Physician in Florence.—Dr. Winslow W. Skinner, formerly of New York and for several years a member of the staff of the *New York Medical Journal*, informs us that he is now the only American physician practising in Florence, Italy. An American who practised there for many years has disposed of his practice to a British physician and left Florence.

The German Medical Society of the City of New York.—At the next regular meeting, to be held in the Academy of Medicine's building on Monday evening, May 8th, Dr. Julius Wolff will show two patients with congenital unilateral paralysis of the abductors, with retractile and protrusive movements of the eye; Dr. J. W. Gleitsmann will show a person who has been cured of primary tuberculous disease of the pharynx and larynx by eighteen months' treatment; and Dr. Henry J. Wolff will read a paper entitled Experiences in Appendicitis.

The Late Dr. W. W. Van Arsedale.—The following memorial notice was adopted by the New York County Medical Association at its stated meeting on April 17th, and ordered to be published in the medical journals:

Resolved, That in the death of Dr. W. W. Van Arsedale the New York County Medical Association has lost one of its most accomplished members. In addition to a thorough academic education, Dr. Van Arsedale passed successfully through the long course of study required at the University of Leipzig, in Germany, from which institution he graduated with honors, and afterward served the required term of service in the great hospital of that city as pupil of, and assistant to, the distinguished Professor Thiersch. Returning to his native country, he located in New York city, became connected as an assistant to the chair of surgery in the New York Polyclinic Medical School and Hospital in the early days of its organization, and served with such faithfulness and proficiency that he gradually rose to the professorship of surgery, which position he filled with entire satisfaction and held at the time of his lamented death. He was also assistant surgeon to the New York Cancer Hospital. For four years before his death he had been assistant visiting surgeon to Mount Sinai Hospital, where his conscientious and thoroughly scientific work was fully appreciated, and where his loss will be keenly felt.

Dr. Van Arsedale was twice elected chairman of the Section in General Surgery in the New York Academy of Medicine, and was an earnest working member of the New York Surgical Society. He contributed many valuable papers upon scientific subjects to the various medical journals, and was justly considered one of the clearest writers of his day upon surgical topics.

[Signed.] JOHN A. WYETH, M. D., *Chairman*,
FRANCIS J. QUINLAN, M. D.,
A. ERNEST GALLANT, M. D.,
Committee.

Lithiated Johannis Water.—The *Medical Press and Circular* for March 15th remarks that a desideratum of lithia waters is that they should contain a definite and adequate proportion of a salt of lithium, and this it has found in lithiated Johannis, to each small bottle of which a grain of lithium bicarbonate has been added.

Genealogy.

The catarrhine ape,
As proved by his shape,
Is the source from which we sprang,
And however we may stick
At this antenatal trick,
We sprang from an orang-outang.

We may manifest rage
At the thought of the age,
And even ignore this feature;
But the anthropoid monkey
Is no greater flunky
Than many a human creature.

S. S. B.

Bequest to the Royal College of Physicians of London.—According to *Science* for April 21st, the will of the late Sir William Jenner bequeaths £10,000 to the Royal College of Physicians of London.

The New York Academy of Medicine.—At a stated meeting, on Thursday evening, the 4th inst., the following papers were presented for discussion: Anæmia as observed in Gynecological Practice, with Some Practical Suggestions as to Diagnosis and Treatment, by Dr. W. Gill Wylie; and The Present Status of our Knowledge of Chlorosis, by Dr. Thomas S. Southworth. Dr. W. H. Katzenbach, Dr. F. P. Kinnicutt, Dr. M. Manges, Dr. J. Ewing, and others took part in the discussion.

At the next meeting of the Section in Surgery, on Monday evening, the 8th inst., Dr. J. E. Kelly will read a paper entitled An Original Method of Closing a Biliary Fistula after Cholecystectomy, and Dr. Charles N. Dowd will present two patients with tuberculous epiphysitis without involvement of the joint.

At the next meeting of the Section in Genito-urinary Diseases, on Tuesday evening, the 9th inst., Dr. Ramon Guitéras will read a paper on Bottini's Operation for Prostatic Hypertrophy, with a Report of Cases. Cases will be reported, and new instruments and specimens will be exhibited.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 11th inst., the following papers will be read: The Frequency of Otitis in the Exanthemata and the Indication for Early Interference, by Dr. Charles H. May; Mastoid Complications in Otitis of the Exanthemata, by Dr. Edward B. Dench; and Otitis of the Exanthemata from the Standpoint of the Pædiatrician and General Practitioner, by Dr. J. Henry Fruit-night. Patients will be presented and new instruments will be exhibited.

The Medical Review.—The *Medical Review* of St. Louis has changed hands, having been purchased by Dr. Heman W. Loeb of that city, who, as editor, will continue its publication.

A Consolidation of Kansas City Journals.—The *Kansas City Medical Index* and the *Kansas City Lancet* have been consolidated. Dr. John Panton is the editor of the journal thus formed.

Original Communications.

PHOCOMELUS OF THE HUMERUS
IN EPILEPSY
AS A STIGMA OF DEGENERATION.

WITH REPORT OF TWO CASES.*

By L. PIERCE CLARK, M.D.

FIRST ASSISTANT PHYSICIAN, CRAIG COLONY, MONTEALE, N. Y.
MEMBER OF THE NEW YORK NEUROLOGICAL SOCIETY;
FELLOW OF THE NEW YORK ACADEMY OF MEDICINE;
MEMBER OF THE NEW YORK PATHOLOGICAL SOCIETY, ETC.

As a prefatory remark, before speaking of the special title of this paper, I wish to say that if the frequency and number of stigmata found in any disease are a sign of its degree of degeneracy, then we find epilepsy taking front rank with idiocy and imbecility. It is certainly a much more degenerative disease than the ordinary insanities. In an examination of over four hundred cases of epilepsy for various stigmata at the Craig Colony, I was struck with the remarkable frequency of asymmetry of hard and soft parts. Slight asymmetries are very frequently found in the normal state, therefore only the most marked conditions were counted as stigmata.

As to what defect in development stigmata may be dependent upon, and as to what relative value should be given them, singly or collectively, from a clinical point of view, does not immediately concern us in this paper. Such questions still remain in the domain of conjecture or hypothesis.

Remarks on Defects of the Humerus as a Degeneration Stigma in Epilepsy.—Information on this point ought to be found in one or more of half a dozen independent lines of research. These are general anatomy, anthropology, abnormalities, monstrosities, degeneration stigma, and, finally, epilepsy proper.

Under the head of anatomy we find a good deal on what is termed asymmetry within normal limits, and statements are made to the effect that half or three quarters of an inch difference in the length of the two humeri may occur simply as a natural variation. That is to say, the right humerus is naturally a very little longer than the left—probably from right-handedness—and the limit of this variation might reach the exceptional extent of half or three fourths of an inch. Hence a variation of this sort would not necessarily be a stigma if found in an epileptic. In the case of Raymond and Janet the shortening of the humerus was only one centimetre.

The writer has had some misgivings about the title of this paper. He uses the term phocomelus, a shortening of the extremity, from its derivation, not in its application to monstrosities, as we may have no right to say that a defect of several inches of the humerus should be classed as a phocomelus; the fact being that in liter-

ature phocomelus is a pure "monstrosity," while defect of the humerus is only an "abnormality." The two have entirely different literature and affinities. Monsters seldom live, and hence the literature of monstrosities is principally made up of autopsies. On the other hand, abnormalities are usually described in the living, and probably there are as many adults as children represented. In looking over monstrosities in literature, the number of individual varieties is so great that I see no trace of any attempt to study any one variety in connection with any outside subject like epilepsy. Phocomelus seems to receive rather less attention than many other varieties—ectromelus, for example, polydactylia and syndactylia, etc.—which seem fairly common. Virchow has recently written on phocomelus, but the work is not at hand.

With regard to the consideration of monstrosities as a whole in relation to epilepsy, the only reference I have been able to find is Zuccarelli, who makes no mention of the conditions.

The literature of abnormalities is very large, and the classification of "abnormalities of the extremities" in the *Index Medicus* contains many titles; but it is very obvious that the humerus has far fewer abnormalities than some of the other long bones, and the few instances I have been able to find make no mention of epilepsy or of outside matters in general.

The literature of degeneration stigmata is of recent date, and the Italian school seems to have done most of the work here, but the large work of Tonnino on *Epilepsy and Degeneration* is the only monographic treatment of the subject. We have no mention of shortening or defect of the long bones discussed in this book.

The literature of practical anthropology, or rather anthropometry, is considerable, and appears to have received an impetus from the Bertillon method of identification, and to be favored specially by the French. Thus Bourneville has measured his epileptics carefully for twenty years, long before degeneration stigmata were recognized by the profession as a whole. In spite of Bourneville's frequent allusions to asymmetry of the skull, face, etc., there is nothing to show that he suspected anomalies of the long bones as accompanying epilepsy. He speaks of *asymmetry*, but not of *defects* or *monstrosities*. Here, the other, again, a stigma appeared hardly to recognize these matters, even in his earlier works, and only in *Les épileptiques* he finally admits that shortening of the humerus is a stigma of epilepsy. He gives measures of forearm bones, but I am sure we have had reference to the same matter in a photograph by Dr. Peterson, as I have seen that one of his cases in the 1890 book, and he has exhibited any shortening.

Coming now to the subject of this paper, we have gone over the literature for a number of years back and have consulted the leading authorities freely, but the

* Read before the Section in Pediatrics of the New York Academy of Medicine, December 8, 1898.

only recorded case deliberately reported of shortening of the humerus as a degeneration stigma of epilepsy is the one published by Raymond and Janet, and here the shortening is so slight that it could hardly be placed in the same category with the cases which I shall report in this paper.

Hence we are forced to conclude that if any other cases exist they should be found in the works of Tonnino and Zuccarelli, or else are mere casual and incidental mentions scattered aimlessly in literature and having little value. German, English, and American authors are certainly less inclined, as a rule, to do justice to subjects of this kind. Thus Oppenheim, Sachs, and other writers either ignore or barely allude to the occurrence of stigmata, etc.

*Case of Shortening of the Humerus as a Degeneration Stigma in an Epileptic.**—This epileptic is a girl of nineteen years. There is almost complete asymmetry of the body. Skull irregular, left side of face less developed, left side of thorax smaller.

The two arms vary in length. On the left side the distance from acromion to epicondyle is twenty-eight centimetres to twenty-nine centimetres on the right side. The two forearms are also asymmetrical to the same extent.

This shortening, while insignificant, is enough to show in a photograph. There is corresponding shortening in the lower extremities. Patient looks in the photograph as if she had had hip disease.

Age when first had fits, sixteen years. Father's sister epileptic. I do not consider this case above suspicion of being dependent upon an organic brain lesion, so often seen in the various cerebral palsies of the young.

FÉRÉ.—On account of his eminence and the voluminous character of his writings, we expected to find something on stigmata which would illustrate the matter of defects of long bones.

In his chapter on Diagnosis of the Predisposition (*Épilepsie*, etc., 1890) he says that recognition of asymmetry began with Lasègue, but that he did not go beyond the head and face.

Vielle, in 1878, wrote on epilepsy associated with malformations, and gave measurements of hands and feet. (Not in New York Academy.)

In 1885, Zuccarelli gave measurements which showed asymmetry of the thorax in epileptics.

It is evident that up to 1890 Féré had no definite knowledge of shortening of the limbs as a stigma of epilepsy; but in *Twentieth Century Practice* he gives among the stigmata of epilepsy "shortening of the limbs." This is the only allusion he makes to this subject.

BOURNEVILLE AND ASSISTANTS.—On account of the pioneer and exhaustive work done by or through Bourneville on all the peculiar features of epilepsy, and especially because of the system of measure-

ments which he has carried out for years, we expected to find some data as to defect, etc., of the long bones. In the many histories which he gives in detail, the length of the humerus is universally recorded. He states over and over that "there was no inequality," or perhaps a very slight difference in favor of the right bone.

In perhaps a half-dozen cases, Bourneville records a high degree of *progressive* shortening consequent upon hemiplegia with which the epilepsy was associated. While this sort of shortening bears no relation to defects which are congenital stigmata, it may be of interest to give a few of these cases on a separate page. Such cases are frequently seen by the neurological observer, and should not be confounded with the subject of the writer's paper.

Outside of these cases we find absolutely nothing touching upon the matter in question.

Cases of Shortening of Humerus due to Paralysis.—

Bourneville: * Child of ten years with pseudoporencephaly, left hemiplegia, partial epilepsy. Length of right humerus, twenty-eight centimetres; length of left humerus, twenty-five centimetres. One year earlier the right humerus was only 0.5 centimetre longer, a gain of 2.5 centimetres in a year.

Bourneville: † Idiot with right hemiplegia and consecutive epilepsy; hemispherical cerebral sclerosis.

* In 1879, right humerus, thirty-two centimetres and a half; left, thirty-two centimetres. In 1886, right humerus, thirty-seven centimetres and a half; left, thirty-two centimetres and a half. There is, therefore, a shortening of two inches.

Other similar cases are found in Bourneville's work, but these two are much the more striking.

ITALIAN AUTHORS.—Since the work done by Lombroso on degeneration stigmata in criminals, epileptics, etc., it is but natural to expect to find something bearing on defects of the long bones, etc., in the work of his disciples. He himself does not discuss anything to the point. In 1891 Tonnino published a book of 324 pages on the relations of epilepsy to degeneration.‡ The work is briefly reviewed by Seppilli in the *Revista sperimentale di freniatria*, 1890, and no reference in the original or in the review appears upon bones.

Donaggio contributes an article on development of the limbs, etc., in epilepsy in the *Revista sperimentale di freniatria* for 1891, but refers only to the muscular development. He gives numerous measurements of the circumference, the length being ignored.

In 1885 Zuccarelli wrote on asymmetry of the thorax in epileptics.

In 1898 the same author, or one having the same name, published an article on "human monsters and epilepsy" (*mostri umani ed epilessia*) in an Italian periodical called *Anomalo*, which has been in existence

eight years. The academy has no file of this periodical, which is devoted rather to anthropology, biology, etc., than to medicine. It is published at Naples (1898, vol. viii).

MISCELLANEOUS.—Virehow has recently published an article on Phocomelus (*Die Phokomelen*, etc.) in the *Transactions of the Berlin Anthropological Society* for 1898. (Not in the academy.)

Asymmetry of the Humeri as an Anthropological Fact.—Guldberg, a Scandinavian, considers this question from a purely physiological standpoint, nothing being said of degeneration.*

Arnold found the right arm longest in eighty-seven per cent. In only one case out of sixteen was perfect asymmetry present.

Krause found the right arm (upper arm) four per cent. longer than the left.

Rollet, in a hundred men and women (fifty of each), found but two cases of symmetry of humeri. In three cases the left humerus was the longer, while in ninety-five the right was longer. Average difference, five millimetres. It is not uncommon to find seven or eight millimetres, while even such disparity as 1.2 centimetre and 1.8 centimetre was recorded without being looked upon as pathological.

Von Hasse examined over five thousand soldiers. In seventy-five per cent. the right humerus was longer and the left in nine per cent. As a rule, the left humerus was longer in left-handed people, but there was one exception.

The latest writer on this subject before Guldberg was Matiezka.† He sums up as follows:

1. In adolescents the extremities are frequently symmetrical in length. The right is usually the longer, especially in the male.

2, 3. In the adult symmetry is rare, the right side having the preference, as before.

Several of the writers cited by Guldberg, and including the latter, evidently believe that the weight of the bones is a better test of preponderance than the length. They carefully record the weight of the humerus in all researches on the skeleton.

In regard to these cases which I shall present, noting the frequency of Little's disease and infantile cerebral palsy, one should not be led to class such cases with phocomelus, especially those infantile types in which the arm remains paralyzed while the other parts of the hemiplegia have recovered more or less. No sensory or motor disorder is present in either case in the arm showing phocomelus.

The first case was shown in photograph by Dr. Fredrick Peterson, of New York, in his article upon *Stigmata of Degeneration*, published in *State Hospitals Bulletin*, July, 1896, but since the case has come under my

observation I find he barely mentioned the possibility of the condition without giving any history or measurements of the case. I take this opportunity to place the case regularly on record.

The case is one of double interest, as the side opposite phocomelus has been hemiplegic from early infancy, a fact which Dr. Peterson did not report.

The history and description of the case is as follows:

CASE I.—L. S., a girl, aged nineteen years; of Irish parentage, single, and of no occupation. Has had epilepsy since three or four years of age (exact year unobtainable). Father intemperate and mother had rheumatism. Patient is seventh child in family of three girls and four boys. Mother died of phthisis at forty-one years; father died of unknown disease at fifty-three.

Patient was a full-term child; delivery was instrumental, and labor was prolonged. Patient was injured on left side (probably birth palsy) and had several convulsions after birth. She was subject to "fits of crying spells" from infancy, and when dentition began at three months of age she had great difficulty in digestion and malassimilation. Several convulsions occurred at this time also. She began to walk at fifteen months, but suffered for two or three years of early life from suppurating scrofulous glands in the neck.

When about three or four years of age she had several severe convulsions which ended in left-sided hemiplegia; afflicted also with mobile spasm of an athetotic character. The second attack occurred about two months after the first. Her attacks for many years were confined to the left side, and always began there. She occasionally has what the French writers term partial epilepsy, which is as follows:

Four attacks of the same general character occurred April 6th while at the colony. Attacks began with convulsions in left side of face, unattended by the epileptic cry. Her head was drawn to the left, then the tonic spasm was changed to clonic spasm; eyes were wide open and staring, while pupils slowly and widely dilated. The hands were not clinched or even closed during the attack. Convulsive movement was confined to left side of face. Following the convulsion copious frothing at the mouth took place. The unconsciousness following convulsion lasted but a few seconds. Her seizures are generally of grand-mal type, mostly confined to left side, although usually general after invasion is complete. Her attacks are almost always preceded by epigastric aura, a fact fully recorded by flowers—viz., that hemiplegic epileptics may after a time develop aura similar in all respects to those occurring in diphtheries. She has had as many as seventeen fits in twenty-four hours.

Physical examination showed a general poor physique; body poorly nourished, left internal strabismus;

* *Norsk Mag f Lægevidensk.*, 1897.

† *Ueber Asymmetrie d. Extrem.* *Prag med Wochen*, 1896.

pupils dilated; left pupil larger. Breath was foul; she was constipated and showed marked symptoms of bromic poisoning. All deep reflexes were exaggerated on left side. Right arm was in all respects normal except as to length. Measurements are given at end of report of this case.

We must remember that we are not comparing the shortening of this humerus with a normal one, but with a defective development of a left hemiplegic of three or four years of age. The comparison would be much more striking if it were as in Case II, to follow. Both patients are ambidextrous and equally strong right or left. The physiological compensation of throwing the right shoulder forward to make up the shortening of the right humerus is present in both cases.

The mobile spasm in this case at times closely resembles true athetosis, as so well described by Hammond and illustrated by Strümpell. Intentional movements of the hemiplegic extremities are always overacted; this is also apparent even in the face in emotional and volitional acts. Athetoid movements are most typical in the thumb and big toe of left side. The patient presents the customary mental weakness of a hemiplegic and epileptic. The writer's attention was directed to the possible explanation of the phocomelus in this case upon the basis of a prenatal palsy or some intra-uterine injury. Such an injury could hardly fail of attention by the mother and family. No history of such was obtainable. Again, in regard to the first explanation urged by a colleague, in no instance of Little's disease, or that of a cerebral hemorrhage at birth, do the parts maintain their former freedom of movements; there is either flaccidity or contracture.

The history and description of Case II are as follows:

CASE II.—A. A., a woman, aged twenty years; nativity, United States; single; no occupation. October 6, 1898, she was admitted to Craig Colony suffering from epilepsy dating from eighteen years and a half.

Family History.—Aside from deaf-mutism in a paternal uncle, and consumption and rheumatism in mother, the family history was good or negative. The patient is the sixth child in a family of seven, five girls and two boys. The two boys died; one of diphtheria at two, the other of cholera infantum. No history of trauma or complication during her mother's pregnancy. Patient was born at full term, and was a

healthy child. No instruments were used, and labor was not prolonged. Nothing unusual of right side was noticed until two years of age, when the knee became very painful, swelled, and she was unable to use it. After a period of several months (two years?) contracture and rigidity necessitated a tenotomy of the Achilles tendon; a year after this operation another was necessary, and an amputation just above the knee was done. This condition was in all probability tuberculosis, from the relatives' description. The right arm became an object of attention at this time, and the surgeon said probably the arm was paralyzed once. This explanation proved convenient until the family physician said rightly that such an explanation was impossible in view of the fact that the patient still maintained such perfect use of the limb. No further explanation or comment was made until she was brought to my attention at Craig Colony, when, from the examination of the case, I judged her worthy of a somewhat lengthy report. Patient has one sister who is of short stature; aside from this, no such phenomenon was ever present in the family, even if this fact has any bearing on her abnormality.

History of Epilepsy.—Her epileptic seizures at first were *grand mal* in form, occurring every two or three months; now they are lighter, of *petit-mal* type, but generally convulsive, occurring every five or six days. She has never had any warning before fits, which generally occur in the early morning hours. She is bright and capable physically, notwithstanding she was not able to learn at school and uses crutches to get about.

Physical Examination.—Physical examination mostly negative. Of good physique; nutrition well maintained. Left pupil was found much larger than right; vision was poorer in left than in right. Super-

ficial and deep reflexes apparently uniformly normal. On examination of the shortened humerus it was found that the condyles were much enlarged and protuberant. The lower part of the bone had apparently suffered as much as the shaft in the process of dwarfed development. The lines running from shaft to condyles were proportionately shortened. Probably this latter fact accounted for the muscular atrophy or lack of development of the supinators and flexors of the right arm. The line to internal condyle was a little shorter than that to external condyle.

INHIBITION.*

By S. J. MELTZER, M. D.

INHIBITION means a temporary diminution or abolition of a vital activity brought about by an external or internal stimulus. The prototype of this phenomenon is the cardio-inhibitory effect of stimulation of the peripheral end of the pneumogastric nerve. Although numerous instances of inhibitory processes have been unearthed since the cardiac inhibition was first discovered, now a little over half a century ago, inhibition has not yet occupied a proper place in biology. Used only vaguely in psychology, and used arbitrarily and indiscriminately in clinical medicine, the phenomenon of inhibition is distrusted in physiology, had to fight on general grounds at every step for the establishment of any new fact, and has still to fight for recognition as an independent vital force. It is a characteristic and instructive incident in the history of our subject that a famous physiologist clearly saw cardiac inhibition long before its discovery, but dismissed it simply as an error of observation.

A. W. Volkmann (1), in 1838, while systematically examining all the branches of the pneumogastric nerves in the frog, reported among other facts that in one instance the heart was beating twenty times to the minute. After stimulating the peripheral end of the vagus the heart stood still for a minute and a half, and then started beating again twenty-six times to the minute. Volkmann, who was only anxious to know whether the cardiac vagus contained motor- or sensory-nerve fibres, set the incident down then as something very curious. Four years later (2), while writing on the fallacies of certain experiments, Volkmann briefly dismissed these observations of his as invalid. But the brothers Weber (3), only three years later, when making the same observation, recognized it as a new phenomenon and named it inhibition. The failure of Volkmann to properly interpret the phenomenon, as well as the vehement resistance which was offered by many well-known physiologists to the interpretation given to the phenomenon by the brothers Weber, was based, implicitly, or avowedly, upon the well-founded principle that no phe-

nomenon should be acknowledged as presenting a new type of facts unless all attempts to explain it by facts already known proved to be futile. The history of such attempts is quite interesting. Schiff (4), Budge (5), Moleschott (6), and others, for many years insisted that the vagus was the motor nerve of the heart, but it was so sensitive that any artificial stimulation fatigued it at once. Hence the diastolic standstill. When Pflüger (7) discovered the inhibitory effect of the splanchnic nerve upon intestinal peristalsis, Schiff (8) again offered fatigue as the explanation of the inhibitory effect.

Goltz (9), who, when Rosenthal (10) described the inhibitory influence of the superior laryngeal nerve, exclaimed, "Let us resist the flood of inhibitory nerves," but afterward enriched our knowledge of reflex inhibition with a great number of facts, offered (11) in essence as a real explanation of the central inhibition, that the new stimulus fatigued the centre. Again, when Houbnoff and Heidenhain (12) reported that certain stimuli applied to the cortex caused a relaxation of tonically contracted muscles, which the authors considered as an inhibitory action, H. Munk (13) suggested that the applied stimulus might have caused the exhaustion of the nerves. Next to fatigue, it was the vaso-constriction which was discarded against inhibition. Brown-Séquard (14) suggested that the vaso-constriction of the coronary arteries might be the cause of the standstill of the heart; Rosenbach (15) offered the hypothesis that the vaso-constriction of the blood-vessels of the medulla might be the cause of the respiratory inhibition; and S. Mayer and von Basch (16) attributed the arrest of the peristalsis to the anemia caused by the stimulation of the vaso-constrictors within the splanchnic. I wonder that this theory was not extended to the vaso-dilators; these nerves, it could be said, were nothing else but constrictors of the vaso vasorum.

Munk (17) and Schlösser (18) introduced into the discussion the suggestion that many of the inhibitory effects were only apparent, caused by the counter-contraction of the antagonistic muscles, a state which they stamped with the term pseudo-inhibition.

When Fick (19) reported that a muscle which was in a state of maximal contraction by a natural impulse relaxed when an electrical stimulus was applied to it, which Fick considered as an instance of reflex inhibition, Waller (20) insisted that this was caused simply by the contraction of the antagonistic muscle, in spite of the assertion of Fick to the contrary.

While the fatigue and the vaso-constrictor hypotheses have been gradually abandoned, mostly by their originators themselves, the reason of pseudo-inhibition is still welded in a general way by the opponents of inhibition.

It is the object of this paper to give a review of the facts of inhibition as they have been found in all the systems of the living body, and to discover of the

* Read before the New York Academy of Medicine, January 19, 1899.

effect of the vagus upon the heart, thus enabling us to pass judgment upon the place to be accorded to the phenomenon of inhibition among the fundamental manifestations of living matter. So far as I know, it is the first attempt of that kind, and I shall have to ask for your indulgence with the shortcomings of this paper, of which, I am sure, there will be an abundance.

In presenting the facts I shall not follow the historical line, but shall try to group them according to their relation to certain systems, beginning, *ad libitum*, with the digestive system.

Inhibition in the Gastro-intestinal Canal.—The best-known inhibitory phenomenon in the gastro-intestinal canal is the effect of stimulation of the peripheral end of the splanchnic nerve upon the peristalsis of the small intestines, which was discovered, as stated above, by Pflüger (21). He stimulated the spinal cord and observed the arrest of the peristalsis. The stimulation had no effect when the splanchnic nerves were cut; but then he obtained the same result when the peripheral ends of these nerves were stimulated. When later the presence of the vaso-constrictors in the splanchnic nerves was discovered, it was suggested by S. Mayer and S. von Basch (22) that the arrest was not due to an inhibitory impulse, but to the anaemia of the intestines brought about by the considerable constriction of the small arteries. However, Van Braam-Houckgeest (23) has demonstrated that the inhibitory effect is entirely independent of the changes in the circulation. Ehrmann (24) went a step further in the analysis of the inhibitory effect, inasmuch as he was led by certain experiments to make the assertion that the stimulation of the splanchnic nerve caused inhibition of the circular and contraction of the longitudinal muscle fibres. Courtade and Guyon (25) have recently stated that the normal effect of the stimulation of the splanchnic nerve is just directly opposite to that alleged by Ehrmann—*i. e.*, that the circular fibres contract and the longitudinal fibres relax. The same authors, however, admit that after the animal's death they, too, have observed facts similar to those described by Ehrmann. However this may be, it is quite sure that the splanchnic nerve contains inhibitory as well as motor nerve fibres for the small intestines, but that with artificial stimulation the effect upon the first set of fibres seems to predominate. Courtade and Guyon (26) have also reported that the abdominal sympathetic contains inhibitory fibres for the large intestines. Pal (27) reported recently that stimulation of the spinal cord even below the centres for the splanchnic nerves caused inhibition of the intestinal peristalsis. Ehrmann (28) has made the further assertion that stimulation of the peripheral end of the vagus causes the relaxation of the longitudinal and contraction of the circular muscle fibres of the small intestines, just the reverse of the effect which is brought about, according to the same author, by stimulation of the splanchnic. It is the peculiar relation of both nerves to both mus-

cular coats of the intestines which von Basch and his pupils term crossed innervation. Besides Ehrmann, also Morat (29) and Bechterew and Mislawsky (30) are to be quoted among those who believe that the vagus contains some inhibitory nerve fibres for the intestines. The majority of the numerous writers on this subject speak only of the presence of motor fibres in the vagus, and the latest investigators, like Courtade and Guyon in France and Bunch (31) in England, assure us that they have never observed any effect upon the intestines following the stimulation of the vagi.*

Another pupil of von Basch, L. Fellner (32), has described also for the rectum the mechanism of the crossed innervation. According to Fellner's statement, stimulation of the hypogastric nerves causes contraction of the circular and relaxation of the longitudinal muscle coat of the rectum, while stimulation of the nervi erigentes causes just the reverse—contraction of the longitudinal and inhibition of the circular muscular coat. Exner (33) has made some criticism upon the conclusions of Fellner, believing that certain mechanical factors were not taken into consideration. Fellner (34), however, repeated his first experiments under new precautions and obtained the same results as before. Gaskell (35) states that he has examined this question and entirely indorses the conclusions of Fellner. On the other hand, Langley and Anderson (36) remark that they have not been able to confirm Fellner's statement with regard to the crossed innervation, though they have not disproved it either. However, these latter observers themselves, in a careful study of this subject, have established the facts that in rabbits, for instance, the lumbar nerves contain inhibitory fibres for the descending colon and rectum, and in the sacral nerves inhibitory fibres are present for the internal sphincter ani and for the muscles of the skin in the anal region.

For the pylorus, Oser (37) has found in two series of experiments that stimulation of the peripheral end of the splanchnic nerve opens it when it is contracted, and that stimulation of the vagus contracts it when it is relaxed. Oser reports further that stimulation of the splanchnic nerve abolishes the peristalsis of the stomach, while the stimulation of the vagus starts it anew. With regard to the inhibitory effect of the vagus upon the stomach, certain experiments which have often been successfully repeated upon the frog are of special interest. If the medulla oblongata is destroyed, or the vagi are cut, a lively peristaltic movement in the stomach puts in an appearance. These experiments are usually ascribed to Goltz (38), who, indeed, published them in 1872.

* The latest writers on this subject, Bayliss and Starling, in the *Journal of Physiology*, vol. xxiii, *Proc. of the Phys. Soc.*, p. ix, state that the typical effect of stimulation of the vagus upon the intestinal peristalsis is, first, inhibition alone, then inhibition plus augmentation, and, finally, after cessation of stimulus, an immediate and great augmentation.

I wish, however, to state here that these experiments, with exactly the same results, at least so far as the destruction of the medulla and section of the vagi are concerned, were published by A. W. Volkmann (39) in 1841, thirty-one years before Goltz. The appearance of a movement after the section of the vagi, in a stomach previously at rest, seems to indicate that in a normal state these nerves exert an inhibitory influence upon the stomach. Volkmann, of course, could not at that period think yet of inhibition. Goltz, to whom this interpretation suggested itself, indeed, refused to entertain it, on the peculiar ground that he could not conceive the idea that one and the same trunk could contain inhibitory as well as motor-nerve fibres. The truth is, as I may remark already here, that in the majority of the inhibitory phenomena some or most of these nerve fibres are found in the same nerve trunk with the motor fibres. Therefore, Contejean (40), Steinach (41), and others who have studied the above-quoted experiments, have indeed accepted the interpretation that the vagus contains inhibitory nerve fibres for the stomach. Morat (42) and Wertheimer (43) have obtained inhibitory effects upon the stomach from the central end of one vagus when the other vagus was intact. The direct stimulation of the peripheral end has given to many observers unsatisfactory results. I may be permitted to report here very briefly the method by which I have been enabled to observe the inhibitory effect of the vagus upon the stomach in dogs. When in a well-anesthetized animal with a perfectly quiet stomach the peripheral end of the vagus is stimulated with induction currents, a long, latent period passes by before well-marked contractions of the pyloric part of the stomach put in an appearance; the contractions continue for some time after the interruption of the stimulation. If now, while the contractions from the after-effect of the preceding stimulation still continue, a new stimulation of the vagus is set up, we see a quick diminution or entire disappearance of the movements during the latent period; which means that during the latent period preceding the motor effect of the stimulation an inhibitory effect is exerted upon such movements as are then present.

For the cardia, Kronecker and myself (44) have established the fact, for rabbits at least, that at the onset of each deglutition the cardia, which is usually tonically contracted, becomes perceptibly relaxed—i. e., the tone of the cardia is diminished, inhibited. When many deglutitions follow one another in rapid succession, the tonus may be entirely abolished. This relaxation takes place even when the œsophagus is severed, but disappears when the vagi are cut, which goes to show that the relaxation is a genuine nervous phenomenon of central origin, and not simply a mechanical effect. In connection with our observations von Oppenhow (45) also describes nerve twigs of the vagi in the proximal part of the cardia, from one of which he obtained by stimulation of

contraction, and from another he obtained relaxation of the cardia.*

Also for the peristalsis of the œsophagus which regularly follows each deglutition, Kronecker and myself (46) discovered the presence of a marked inhibitory effect at the very onset of each deglutition. In human beings it was previously established that the contraction of the upper part of the œsophagus set in 1.2 of a second, the middle part three seconds, and the lower part six seconds after the beginning of the deglutition. This is the stable rule after each single deglutition. If, however, a number of deglutitions follow one another at short intervals—for instance, of less than three seconds—no contraction appeared in the middle and the lower section of the œsophagus after each deglutition except in proper time after the last deglutition. This means that each consecutive swallow inhibits the appearance of the peristalsis in the middle and lower part of the œsophagus which were bound to come after each preceding swallow. The same occurrence takes place in the deglutition of dogs and rabbits. And as it was shown by other experiments that the cause of peristaltic movements of the œsophagus was located, at least under normal conditions, not in the œsophagus but in the centre of deglutition in the medulla oblongata, we have to assume that the inhibition, too, takes place within the medulla—i. e., that we have here before us the phenomenon of central inhibition. I shall add that further experiments have shown that apparently the afferent inhibitory impulses are carried to the centre by some fibres of the glosso-pharyngeal nerve (47). It deserves to be especially pointed out that in these observations it was proved for the first time that inhibition is an integral constituent in the normal activity of a function. In all the other experiments the inhibition was brought out by artificial stimulation of a nerve or tissue, which only suggests, but does not prove, that the inhibition is actually participating in the normal mechanism.

The numerous instances which I have just recited demonstrate the important fact that inhibitory nerves or inhibitory effects have been shown, through the labors of numerous investigators, to be present for the movements of the entire alimentary canal from the mouth to the rectum.

Inhibition in the Circulatory System.—We now turn our attention to the circulatory system. The most important inhibitory phenomenon there is, of course, the effect of the stimulation of the peripheral end of the vagus upon the heart. Stimulation of moderate intensity diminishes the tonicity of the heart muscle, reduces the systolic contraction, and lengthens the diastole; stronger stimulation causes a perceptible fall of the heart in diastole. In connection with this there is, in many animals at least, a tonic action of inhibitory fibres

* Very recently E. A. Key (Z. Anat. u. Entw. Gesch., p. 1871) has demonstrated in an interesting way the presence of the vagus of inhibitory nerve fibres for the cardia in the rabbit.

of the vagus—i. e., inhibitory impulses are constantly transmitted from the medulla to the heart; the centre of this tonus is apparently in the proximity of the nucleus of the vagus. Certain peripheral reflexes to the cardio-inhibitory centre increase the inhibitory influence upon the heart. A noteworthy instance of this kind of reflexes is the well-known stroke experiment (*Klopfersuch*) of Goltz (48). If the abdomen of a frog is struck with a scalpel or a similar instrument, the heart stands still in diastole, if the vagi are intact. It should be mentioned that about twenty years after the discovery of the cardio-inhibitory nerves, the much-looked-for motor-nerve fibres of the heart were finally found [Bever and von Bezold (49) and Cyon brothers (49)]; they are the accelerating or augmentor-nerve fibres which in the dog are to be found in the loop between the first thoracic and the last cervical ganglion. When stimulated there, the accelerating effect is quite marked; but in the frog, where the augmentor fibres are, together with the inhibitory nerves, in the trunk of the vagus, the stimulation shows only the inhibitory effect, and the presence of the augmentor fibres can be recognized only after the cessation of the stimulation, by virtue of their long after-effect [Heidenhain (50)].

Regarding the blood-vessels, we may now assert that vaso-dilators are present all over where also vaso-constrictors can be found. Both kinds of fibres often run in the same trunk, and the effects of the dilators are concealed by the overpowering effects of the constrictors. In some places, however, nerve trunks can be found which contain only vaso-dilators. The chorda tympani, for instance, contains, as was discovered by Claude Bernard, the vaso-dilators for the submaxillary gland; the stimulation of the peripheral end of this nerve changes the color of the gland, and increases considerably the flow of blood from the veins so as even to attain a pulsating character [Claude Bernard (51)]. The vaso-constrictors for this gland are present in the cervical sympathetic [Bernard (52)]. The relations of these two nerves to one another, which have been studied by von Frey (53), are the exact reverse of the relations existing between the vagus and augmentor nerves with regard to the heart, and are extremely interesting with regard to the question of inhibition, which, however, can not be discussed here. The vaso-dilators are nothing else but nerves which can inhibit the contraction of the circular muscle fibres caused either by the vaso-constrictors or by the tonus present in the arterial muscles even after section of the vaso-constrictors; they are simply inhibitory nerves for the arteries, as the fibres of the vagi are inhibitors for the heart. The nervus depressor which was discovered by Ludwig and Cyon (54) presents an instance of a nerve trunk transmitting only inhibitory impulses for the vascular system in a centripetal direction. The vaso-constrictors are in a state of tonus, which is kept up by a centre in the medulla oblongata—the vasomotor centre.

When the central end of the depressor is stimulated, the blood pressure sinks considerably, which is generally interpreted by the assumption that the depressor is an inhibitory nerve for the vasomotor centre. The assumption of Bayliss (55) that the depressor carries impulses to a vaso-dilator centre in the medulla is, as Reid Hunt (56) justly remarks, unsupported by any evidence.

In connection with the vascular system I shall also speak of the spleen. This organ contracts when the splanchnic nerves are stimulated, and Roy (57) has found that it shows constant rhythmic contractions even when it is deprived of all nerves. Now, Schaeffer and Moore (58) have recently discovered that the splanchnic nerves contain also nerve fibres, the stimulation of which inhibits the rhythmic contractions and causes an expansion of the spleen; in short, they have discovered inhibitory nerve fibres for the spleen.

Camus and Gley (59) have recently discovered the presence in the splanchnic nerves of fibres dilating the receptaculum chyli and thoracic duct, which nerves are to be compared with the vaso-dilators of the blood-vessels. In this connection it is interesting to mention that the lymph hearts, which present the moving power for the lymph in amphibia and reptilia, also show inhibitory phenomena. Goltz (60) has found that mechanical stimulation of the abdominal viscera or blood heart causes a diastolic standstill of all the four lymph hearts in the frog. This reflex is unsuccessful if the medulla oblongata is destroyed. According to Volkmann (61), the centre for the movement of the lymph hearts is located within the spinal cord. Then the nerve fibres stretching between this centre and the medulla will be the carriers of the inhibitory impulse to the centre, which would be, as Goltz says, an instance of intracentral inhibition. Eckhard (62), however, and others state that the second and tenth spinal nerves correspond to the vagus, inasmuch as the stimulation of the peripheral ends causes the diastolic standstill of the lymph hearts. However this may be, it is an assured fact that the rhythmic beat of the lymph hearts can be inhibited by active stimulations just as the rhythmic beats of the blood hearts can be actively inhibited.

Inhibition in the Respiratory Apparatus.—We have just seen that inhibition was discovered and established for the heart, blood-vessels, spleen, lymphatics, and the lymph hearts. We will now proceed to examine the respiratory mechanism. Rosenthal (63) has discovered that stimulation of the central end of the laryngeal superior nerve causes inhibition of the inspiratory muscles. The same was found by Hering and Kratschmer (64) for the second branch of the fifth nerve, and by Graham (65) for the peripheral end of the splanchnic nerve. Hering and Breuer (66) established the fact that distention of the lungs caused an inspiratory standstill with relaxed muscles. And of the prolonged controversy about the nature of the effect of the stimulation of the central end of the vagus, it can be stated

that at present nearly all the authors agree that also expiratory standstills can be obtained, and I (67) have shown, by means of a division of the spinal cord, thus paralyzing the expiratory muscles, that these standstills mean genuine inhibition, relaxation of the inspiratory muscles. The same was done by Gad (68) and Wegele (69) for the expiratory standstill brought about by stimulation of the trigeminus. At present all opinions seem to agree that reflex inhibition is a normal factor in the respiratory mechanism. It should be further mentioned that, according to the recent experiments of Doyon (70), the vagus contains inhibitory nerve fibres for the muscles of the bronchi, which can best be seen after poisoning the animal with pilocarpine.

Inhibition of Secretion.—On account of the close relations existing between secretion and circulation it is extremely difficult to establish the presence of inhibitory nerves for the secretion independent of vaso-dilators, which accounts for the meagreness of well-assured facts concerning the working of inhibition in the different secretory functions. It is, however, an encouraging fact that very recently separate nerve fibres coming from the vagi have been discovered for the secretion and inhibition of the pancreatic juice, thanks to the genial methods and persevering labors of Pawlow (71) and his pupils (72), remembering at the same time that until recently there was no positive proof of the dependence of the pancreatic secretion upon nervous influence. Morat (73) attributes inhibitory effects upon the pancreas also to the splanchnicus. Pawlow (71), Ushakow (74), and Contejean (75) speak also of the presence in the vagi of inhibitory nerve fibres for the secretion of the gastric juice. Vulpian and others (76) assume the presence of inhibitory nerve fibres in the cervical sympathetic of the horse for the sweat gland, on account of the profuse sweating which follows the section of the sympathetic. Arloing (77) described lately observations which seem to demonstrate the presence of inhibitory fibres in the sympathetic nerve of the donkey and the cow for the lacrimal as well as for the sweat glands of certain facial regions. There are statements alleging the existence of nerves for inhibition of the secretion of milk, and even for the secretion of the sebaceous glands. While all these assertions might really be true, it can not be maintained that they are proved facts, the more so as in some cases the possibility was not even taken into consideration that the observed antagonism between these called secretion and inhibition might have had reference only to the ducts of the glands—i. e., inhibition or acceleration of removal from the ducts. In this connection the innervation of the bile duct, as it was described recently by Doyon (78), is very interesting. According to this investigator, stimulation of the peripheral end of the splanchnicus causes a contraction of the bile duct and the gall bladder and a relaxation of Oddi's sphincter muscle in the duodenal papilla; while stimulation of the central end of the splanchnic nerve

causes the reverse—the contraction of the sphincter and relaxation of the bile duct and the gall bladder. Stimulation of the central end of the vagus has the same effect as the stimulation of the peripheral end of the splanchnicus. This means apparently that in the centrifugal direction the vagus contains inhibitory fibres for the gall bladder and the bile duct, and motor fibres for the sphincter, while the splanchnic nerve carries motor fibres for the gall bladder and the bile duct, and inhibitory fibres for the sphincter. In the centripetal direction the case is reversed: the vagus transmits afferent impulses which cause the contraction of the gall bladder and the bile duct and inhibition of the sphincter, while the splanchnicus would cause reflexly the inhibition of the gall bladder and bile duct and contraction of the sphincter. This is a striking example of a double-crossed innervation, which would beautifully explain the mechanism of the storage of the bile in the bladder or its discharge into the duodenum.

Inhibition of the Genito-urinary Organs.—The nerves which assist in the production of bile and the excretion of urine, outside of the vascular influence, are yet to be found. For the bladder, von Zeissl (79) reports having found a mechanism of crossed innervation modeled after the pattern described by Ehrmann and Fellner for the intestines and the rectum—viz., that the nervi erigentes control the contraction of the detrusor and the relaxation of the sphincter muscles, while the hypogastric nerves control the contraction of the sphincter and the relaxation of the detrusor. Langley and Anderson (80) state that the inhibition fibres for the bladder "are few, if any"; neither have von Courtade and Guyon (81) been able to confirm the statement of von Zeissl, so far as the inhibition is concerned. It should be remembered, however, that the function of the bladder is properly executed even without the usual influence of the central nervous system, as it was observed by Goltz (82) in a dog in whom the lower part of the spinal cord was destroyed.

According to Fellner (83), the nervi erigentes contain motor nerves for the longitudinal and inhibitory nerves for the circular muscle fibres of the uterus and the vagina, while the hypogastric nerves contain the motor nerves for the circular and the inhibitory nerves for the longitudinal muscle fibres. Langley and Anderson (84), in their study of the relations of the lumbar and sacral nerves to the uterus and the vagina, did not observe any inhibitory effects upon these organs. The latter writers (85) describe inhibitions obtainable from the sacral nerves for the vulva, the muscle of the skin in the genito-anal region, for the unstriated muscle of the penis, and for the retractor muscle of the penis of the dog. Of this latter muscle the authors say that it, too, "offers advantages for the study of inhibition of unstriated muscular tissue represented by no other muscle in which inhibition is known to occur."

In our search through the vegetative system we have

been able to establish the presence of inhibitory phenomena at nearly all points where motor phenomena are present, and in some of the secretory functions proper investigations have already made quite a successful start.

(To be continued.)

INTRA-UTERINE VAPORIZATION.*

By ABRAM BROTHERS, B. S., M. D.,
 ADJUNCT PROFESSOR OF GYNECOLOGY
 IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL;
 VISITING GYNECOLOGIST TO BETH ISRAEL HOSPITAL
 AND THE NEW-YORKER FRAUENKLINIK.

INTRODUCTORY.—The treatment of hæmorrhage by heat is of ancient origin. We are informed that until the middle of the sixteenth century, when Ambroise Paré revived the use of the ligature, hæmorrhages of all kinds were treated by means of the actual cautery, red-hot knives, boiling pitch, and molten lead. Two centuries later the cautery was still freely used in all kinds of surgery. At the present day the actual cautery is extensively used in hæmorrhoid operations, or in the preliminary stage of a vaginal hysterectomy; indeed, it is possible to do this latter operation completely with the cautery as the sole hæmostatic.

Hot water also has long been known to be of service in the various forms of parenchymatous oozing. At a temperature ranging between 110° and 120° F. it is applied to bleeding surfaces. Surgeons find it useful to apply pads soaked in hot solutions to the extensive oozing surface which is apt to be present during the amputation of a breast, and in post-partum hæmorrhage it has long been the practice of obstetricians to rely upon hot water to cause contraction of the relaxed uterine muscle and blood-vessels.

Heat, as generated by electricity, forms an important element in the electrolytic treatment devised by Skene, which has shown such marvelous hæmostatic power in his own work and in that of Dr. Clement Cleveland.

The use of steam at a temperature of the boiling point or above, for hæmostatic purposes, is of recent origin. Some four or five years ago Professor W. F. Sneguireff, of Moscow, suggested its employment in cases of uterine hæmorrhage. At the present moment the method is being extensively tried in Russia and Germany. So far, with a few exceptions, favorable experiences have been published. Among the most enthusiastic exponents of the new method of treatment is Ludwig Pincus, of Dantzig.

The Apparatus.—Without attempting a description of the earliest models, which were all more or less defective, I shall at once proceed to describe the instrument of Pincus, which is as nearly perfect as one could fairly expect: The steam generator consists of a brass

kettle provided with a safety valve, a central opening for the insertion of a thermometer, and a short elbowed spout, to which is attached the rubber tubing for the passage of the steam. The metal catheter is attached to this tubing, which is of particularly good quality and of any desired length. The kettle rests in a portable holder with a space beneath for an alcohol lamp. The kettles are tested before delivery, and are guaranteed to withstand the pressure of steam heated to a temperature of 125° C. (257° F.) By means of one of the alcohol lamps accompanying the apparatus the steam can readily be raised to a temperature ranging from 100° C. to 110° C. (212° F. to 230° F.) and kept up without danger for any desired period of time.

The nickel-plated uterine catheters are of two shapes, one being a simple hollow sound and the other being a similar sound, but fenestrated at its distal end. The latter, the vaporizer, permits the superheated steam to come in direct contact with the uterine interior; the former, called by Pincus the uterine vapo-cautery, permits the application of dry heat to the same surface. Altogether, the instrument resembles in shape and principle the Fritsch uterine irrigator, but has in addition a metal tube attached for the escape of condensing steam.

Technics.—The patient is placed in the lithotomy position on a table, with a Kelly pad beneath her, and the external genitals are cleansed and the vagina douched in the ordinary manner. Through a short wooden speculum the cervix is exposed and seized in a tenaculum forceps. The uterus is next carefully sounded, and, if the cervix is contracted, it is somewhat dilated by means of slow gradual circular dilatation. With the aid of my four-bladed dilator I have thus far never had any difficulty in accomplishing this result. The uterine catheter, properly protected, is next introduced to a point within a short distance of the fundus uteri and the steam turned on. After a period of time varying between five and thirty seconds, as the necessities of the case seem to indicate, the steam is shut off. On withdrawing the instrument a strip of iodoformized gauze is introduced past the internal os, sometimes to the fundus. During the application of the steam a nurse or assistant may permit a stream of cold water to play against the cervix. In many of my cases I have entirely dispensed with this precaution, as I think the wooden cylindrical speculum sufficiently protects the vagina and vulva from becoming scorched.

The operator and instruments must be surgically clean. The metal instruments are prepared in the usual manner by being boiled in soda solution; the wooden speculum, after being scrubbed with soap and water, is kept in a strong solution of bichloride of mercury until ready for use, when it may be lubricated with sterilized vaseline and introduced into the vagina. In order to prevent scorching of the cervical canal and burning of the operator's hands, it is well to encircle the instrument in gauze up to a point about an inch and a half

* Read before the Society of Alumni of Bellevue Hospital, December 7, 1898. For the discussion, see page 567.

from the top. Sometimes a piece of rubber tubing, slipped over the catheter like a collar, will partly accomplish the same result. Pincus has recently devised a wooden cover for the same purpose.

After-treatment.—It is well for these patients to keep in bed for several days after intra-uterine vaporization. As a matter of fact all of my patients, in whom no additional operative interference was called for, were treated in my clinic at the Post-graduate School or in my office. Many of the women walked a considerable distance after the vaporization, and few of them remained in bed longer than a day or two. In spite of all this I have seen only one case of parametritis, and that in a hospital patient who was put directly to bed. As the preceding curettage was done for an incomplete abortion with large hæmorrhages, it is possible that the pelvic inflammation was the result of other factors. Still, I think it a good rule to order every patient to bed for a number of days with an ice-bag applied to the hypogastrium.*

Sequelæ.—A free leucorrhæal discharge, in some cases blood-tinged or with an odor, will be noted in nearly all of the cases after intra-uterine vaporization. This is undoubtedly due to the destruction of the uterine mucosa with its ultimate discharge. After a number of days the flow diminishes and finally ceases. In case of persistent bleeding a second vaporization, with higher temperature and longer duration, may be called for. Perimetritic irritation or inflammation may follow the procedure. After several days' rest in bed with cold applications locally, these complications usually pass off.

Stricture of the cervix has been observed in a number of cases, and it has been repeatedly cited as one of the chief objections to the method. To prevent this serious complication, it may be desirable to exclude all cases in which there already exists a strictured os. I have repeatedly resorted to dilatation of the cervix, protected the catheter with gauze up to a certain point, usually past the internal os, and packed the uterine cavity with gauze at the completion of the operation in order to avoid this sequel. After forty-eight hours the gauze is removed and, if deemed necessary, fresh gauze is reintroduced. Still, it is only proper to record that, in one of my patients, three months after extensive trachelorrhaphy, curettage, and vaporization (for persistent uterine hæmorrhages, which a previous curettage had failed to

control), I found the external os completely obliterated, and had to push my finger through a thin membranous diaphragm in order to permit the escape of the retained menstrual blood.

Complete obliteration of the uterine cavity may be effected by a protracted application of the superheated steam. Steam heated to 110° C. (230° F.) and applied for two minutes will usually produce this result. Pincus intentionally obliterated the uterine canal in one case. I have used the method with the same object in another, but the time is too short to determine whether or not I have succeeded. It will clearly be appreciated that if the method is feasible it will be applicable in many cases of bilaterally diseased appendages, in which many prominent gynecologists regularly remove the uterus; for, if this organ can be sterilized, cured of its catarrhal condition, and its canal completely obliterated if desired, there is no longer a supporting argument for its removal.

On the other hand, Baruch and von Weiss have each reported a case in which the artificial menopause was unintentionally induced after uterine vaporization. In one of these cases, after an application of steam, heated to 100° C. (212° F.), for forty-five seconds, complete obliteration of the uterine cavity was caused in a young woman of nineteen. The fact that we know that the same result may follow curettage or the intra-uterine application of a caustic is no apology for overlooking this really dangerous sequel of vaporization. I think there was an error in these cases in applying the steam at too high a temperature for a too prolonged period of time. In order to obviate such a disagreeable result, I have made it a rule in ordinary cases, first, not to heat the steam above 106° C. (223° F.); secondly, to limit the application to a space of time varying between five and twenty seconds; and, thirdly, to pass a strip of gauze beyond the internal os in every case at the termination of the procedure. With these precautions I think the chances of an obliteration of the uterine canal will be perhaps entirely excluded.

Indications.—Pincus has resorted to vaporization (or cauterization—he maintains there is no difference!) in the following class of cases: Simple endometritis associated with profuse hæmorrhages or leucorrhæa; irregular hæmorrhages due to subinvolved uteri, myomatous uteri, and hyperplastic or catarrhal endometritis; leucorrhæal conditions due to catarrh or gonorrhœa of the cervix or endometrium; and infected conditions of the post partum uterus. In seventy-eight cases successful results were obtained in sixty-four. One case of puerperal sepsis with general infection died. Pincus believes that the eighty-two per cent. of good results could be improved on if the individual failures were subjected to a second or third repetition of the treatment.

Contraindications.—Intelligent treatment by any method, new or old, presupposes correctness of diag-

* Since this was written, I have ceased vaporizing ambulant patients. A case of syncope and one of extensive parametritis after office vaporization have convinced me that Dohresen is right when (in a very recent article) he advises the employment of this method with proper assistance and under appropriate surroundings—namely, at the patient's home or in a hospital. It is well to add also that one case (Treble's) has terminated fatally from perforative septo-peritonitis. This is the only fatal case, so far as I know, and I believe, with Dohresen and Pincus, that such an unfortunate result can be avoided by the introduction of the vaporizer for a short distance beyond the internal os and by strictly limiting the application to between five and twenty seconds for the first time.

nosis. Improperly used, the best operative procedure may not only fail to do good, but may be distinctly productive of harm. Thus, an early case of carcinoma uteri must not be tampered with by any method of treatment short of radical. When such a case has become inoperable, dry heat or vaporization may be employed as a palliative measure. Hemorrhages or sepsis following abortion or labor demand removal, with the curette, of the placental tissue before vaporization can be resorted to. The two principal contraindications in ordinary cases of uterine hemorrhage are diseased annexa and stricture of the cervical canal. Still, as pointed out elsewhere, the latter object can, in great measure, be overcome by previous dilatation of the cervix, protection of its canal from the heated catheter by the various devices mentioned, and, at the termination of each vaporization, by cervical gauze packing. Diseased states of the annexa must always be excluded before the application of this treatment. Finally, in submucous or polypoid myomata vaporization is contraindicated because of the danger of inducing suppuration.

Personal Experiences.—In testing this treatment during the past six months, I have tried to be very careful in the selection of the cases. Drawing my material exclusively from personal sources, I am not able to give you histories of more than twenty-one cases. These I will describe very briefly.

CASE I.—Frequent and profuse uterine bleedings due to catarrhal endometritis: application of vapor heated to 102° C. (215° F.) for five seconds. The patient complained of no pain and walked home. No subsequent report.

CASE II.—Gonorrhoeal endometritis; profuse discharge, showing large numbers of gonococci present; five-second application of vapor heated to 102° C. (215° F.). A week later, gonococci present, but very much diminished in number. The patient failed to report for subsequent treatment or observation.

CASE III.—Under anaesthesia, four large submucous fibroids were removed after splitting the cervix and drawing down the growths. Curettage of the uterine interior followed by vaporization at 105° C. (221° F.) for ten seconds. Five months later, complete cure.

CASE IV.—Under anaesthesia the uterus was curetted and vaporized for ten seconds at 100° C. (212° F.) for hemorrhagic endometritis. Patient left the hospital at the end of a week perfectly well. No subsequent report.

CASE V.—Fungoid endometritis with lacerated cervix. Under anaesthesia, curettage, trachelorrhaphy, and vaporization at 100° C. (212° F.) the patient left the hospital cured. Three weeks later she reported herself as perfectly well.

CASE VI.—Endometritis causing metrorrhagia; rectocele. Under anaesthesia, curettage, vaporization at 100° C. (212° F.) for ten seconds; posterior colporrhaphy. Four months later the patient reported herself perfectly well.

CASE VII.—Hemorrhagic endometritis with lacerated cervix. Curettage, vaporization at 100° C. (212° F.) for ten seconds; trachelorrhaphy. Four weeks later the patient seemed to be perfectly well.

CASE VIII.—Submucous fibroid causing profuse hemorrhages. Excision of tumor after splitting the cervix under anaesthesia. Curettage and vaporization at 105° C. (221° F.) for ten seconds. Repair of cervix. Four months later the patient reported herself completely cured.

CASE IX.—Profuse flow of blood in connection with incomplete abortion. Under anaesthesia, curettage and vaporization at 105° C. (221° F.) for ten seconds. Parametritis occurred, which delayed the patient's recovery for eighteen days. No subsequent report.

CASE X.—Metrorrhagia due to endometritis; lacerated cervix and perinaeum. Under anaesthesia, curettage and vaporization at 102° C. (215° F.) for ten seconds; amputation of cervix and perineorrhaphy. The patient left the hospital cured.

CASE XI.—Irregular uterine bleedings due to endometritis and retroflexion. Under anaesthesia, curettage and vapo-cauterization at 102° C. (215° F.) for ten seconds; shortening of the round ligaments after Alexander's method. Good result five weeks later.

CASE XII.—After miscarriage, six months previous to consulting me, the patient had been curetted at a hospital for profuse hemorrhage. For three months each monthly period has been a violent gush of blood lasting from seven to eleven days. Nothing but an enlarged flabby uterus to be found. Vaporized at 102° C. (215° F.) for ten seconds, without anaesthesia at the Post-Graduate School before the class. No pain complained of. The patient walked home, a distance of over a mile. Saw her four weeks later, after the next menstrual period, which came on time, lasted five days, and was moderate in amount. She said she had never felt better in her life. [Five months later she was in perfect health.]

CASE XIII.—Metrorrhagia due to endometritis with pyosalpinx (gonorrhoeal). Under anaesthesia, curettage and vaporization at 100° C. (212° F.) for fifteen seconds. Posterior colpotomy with removal of the diseased annexa. Three weeks later the patient was discharged from the hospital cured.

CASE XIV.—Profuse menstrual discharge recurring at intervals of two or three weeks. Owing to haemoptysis (due to tuberculosis?) the patient has feared operative interference. In my office she was vaporized at 100° C. (212° F.) for ten seconds. Her next menstrual flow was anticipated, and again profuse, so that repetition of the treatment was suggested. [See Case XXI.]

CASE XV.—Woman, aged thirty-eight years, probably at climacteric. After four months' absence of menses it occurred, and again returned in two weeks, and persisted for eleven days. In my office she was vaporized at 100° C. (212° F.) for fifteen seconds. Kept in bed for three days. Several days later she was feeling comfortably.

CASE XVI.—Irregular uterine hemorrhages. Last time, after two weeks' absence, blood appeared and flowed continuously for thirteen days. Owing to rigidity of the internal os considerable time was spent in my office in slowly dilating it. Vaporization at 105° C. (221° F.) for ten seconds. Two weeks later she was comfortable.

CASE XVII.—During a period of six months, following a miscarriage, this woman has not been free from a menstrual discharge for more than ten days at a time. She has become very anemic from the almost constant loss of blood. Diagnosis: Hemorrhagic endo-

metritis. Vaporization at 106° C. (223° F.) for twenty seconds in my office. Nine days later she was complaining of profuse leucorrhœal discharge and vague pelvic pains. Otherwise nothing abnormal was found.

CASE XVIII.—Patient, thirty-three years old; acquired gonorrhea from her husband twelve years ago. Leucorrhœal discharge ever since. Three years ago I performed an abdominal section on this woman and removed two large pus tubes. With the exception of the profuse leucorrhœal discharge, due to the chronic endometritis, she has enjoyed good health ever since. Since the operation she has ceased to menstruate. In my office I applied vapor heated to 105° C. (221° F.) for sixty seconds with the object of obliterating the uterine cavity. She went to her home in Hoboken, and for a good portion of the succeeding week remained in bed. A week later she reported herself as feeling well, except for a profuse leucorrhœal discharge which had some odor. This disappeared almost completely during the subsequent week.

CASE XIX.—Girl, aged nineteen years. For three years has suffered from profuse leucorrhœa. For two months the periods have recurred at intervals of two weeks and have been accompanied with considerable pain. Diagnosis: Endometritis dysmenorrhœica. An examination under narcosis excluded annexal disease. Vaporization at 110° C. (230° F.) for nearly ten seconds. A week later she was about, and felt well.

CASE XX.—Multipara, aged thirty-eight years; last pregnancy ten years ago. After six weeks' absence menstruation reappeared and persisted profusely for fourteen days. Diagnosis: Uterine hemorrhage due to climacteric. Vaporized at 100° C. (212° F.) for sixty seconds, inviting an obliteration of the uterine canal. Performed before the class at the Post-graduate School. In this case bleeding was completely checked, according to the subsequent report.

CASE XXI.—Same patient as in Case XIV. Repetition of vaporization because the menstrual flow was anticipated by a week, and lasted profusely for fourteen days. Applied the vapor at 100° C. (212° F.) for forty seconds. As the woman was only thirty-four years old, gauze was introduced into the uterine canal to prevent its obliteration. A few days later she reported herself at the office (where, without anesthesia, the little operation had been done) as being fairly comfortable. [Several months later she reported herself as perfectly well.]

Conclusions.—I appreciate, of course, in presenting the foregoing *résumé* of my experience with intra-uterine vaporization, that my work is still very incomplete. I do not attempt to make sweeping deductions until the subsequent results, after a sufficient lapse of time, shall have proved the true value of the method. I think, however, that I am able to do some service by pointing out in this paper the feasibility of the treatment and the character of the cases in which it is applicable.

Permit me, in conclusion, to summarize the present uses of vaporization or vapo-cauterization.

1. As a *hemostatic* it has been employed most successfully in cases of non-malignant post-climacteric uterine hemorrhages. It has proved curative in the various irregular bleedings met with in connection with catarrhal fungoid, or hemorrhagic endometritis. It acts as a palliative measure in certain cases of fibroid

tumor or inoperable carcinoma associated with hemorrhages.

2. As a *caustic* it can be relied on to destroy the mucous lining of the uterus, even to the extent of obliterating the uterine canal.

3. As a *bactericide* it may be used in cases of gonorrhœal and septic puerperal endometritis. Fenomenow has repeatedly had the uterus (which was subjected to vaporization and later removed by hysterectomy) examined bacteriologically and proved it to be sterile.

4. To *reduce the bulk of the subinvolved uterus*, Pincus has frequently resorted to intra-uterine vaporization with success.

5. In *Chronic Suppurating Fistulous Tracts*.—Fenomenow has reported successful results in cases of abdominal fistule of several years' duration, which had resisted all other methods of treatment.

"INERTIA" AND PEDICLE-TWISTING.

BY CHARLES P. BECKER, M. D.,
BROOKLYN.

ON opening the abdomen for the removal of ovarian and other pedunculated tumors, it is not unusual to find them twisted on their pedicles. Many surmises as to the cause of this have been made, but the aetiology is generally conceded to be a mystery. Probably the torsion may be produced in several ways, but the writer, after reading an essay of Dr. Paul F. Mundé's on this subject in the *Journal* of February 25th last, and finding no satisfactory hypothesis advanced, thought that he could offer one that would explain some cases.

In stating an elementary principle in physics and giving some simple illustrations the writer does not presuppose any ignorance of the subject on the part of the reader, but merely desires to lay a foundation on which to base his theory.

All bodies when at rest have a tendency to remain so, and, when in motion, to keep on moving, unless acted on by a force strong enough to change their condition of rest or motion.* This property of matter is known in physics as "inertia." We have all had personal experience of it many times. When obliged to stand in a crowded car, we have nearly (or quite) fallen backward when it suddenly began to move forward, because our bodies wanted (physically) to maintain their previous relative position in space, and the new force, being transmitted to our feet through the floor of the car, tended to pull them from under us. Again, when

* As absolute rest is unknown in Nature, and all bodies are in motion of some sort—I mean molar motion, not molecular (e.g., a stone lying apparently motionless on the surface of the earth near the equator is traveling in a spiral direction at a speed of over a thousand miles an hour, besides having several other motions in space); it would be equally correct to say that all bodies resist a change in the direction or rate of their motion.

the motion of the vehicle was rather too suddenly retarded, we had to pull ourselves back by the straps to keep from falling or running forward. The same law applies to circular as to linear motion. Were we standing, looking north, at the exact centre of a car placed on a turntable, and this were then suddenly and rapidly revolved to the right, our bodies would tend to keep on facing the north, and would certainly do so if there were no friction between our feet and the floor of the car; similarly, after revolving with the turntable, were its motion suddenly stopped, we should, in the absence of friction, keep on spinning to the right for some time.

Nearly every one has noticed that when a tumbler or other circular vessel containing a liquid is turned round, the latter does not at once revolve with the glass. This is especially noticeable when visible particles are in suspension or floating on the surface.

Take a common tin or enameled wash basin—preferably one that is slightly convex on the bottom, so that it may be spun like a top. Fill it about two thirds full of water and place a large cork on the surface near the centre. When the water has become quiet, note the direction in which the cork points and then spin the basin around. It will make nearly a dozen revolutions before the cork begins to turn in the same direction.

Now vary the experiment in this wise: Stretch two wires or cords across the top of the basin at right angles to each other. Take two strands of floss silk or soft thread; place them together and tie one end to the cork and the other to the wires where they cross at the centre of the basin, leaving a length of four or five inches of the doubled thread between the cork and wires. Let the cork float on the water under the wires and then revolve the basin as before. The cork will remain stationary, but the strands attached to it will become twisted together. The use of two threads is simply to make the torsion more perceptible than if one were employed.

Now, what takes place in the basin may also happen in the human body under analogous conditions. The basin may represent the human basin or pelvis; the cork, a tumor; the thread, a pedicle, and the crossed wires the ovarian or visceral attachment of the pedicle. The relative proportions are of little consequence—it is only the principle that is intended to be illustrated. In the experiment, however, the water and the cork must be considered as one body, for the former, being the heaviest, is really the substance that illustrates the effect of inertia, and the cork makes this visible and serves as a convenient means of attaching the "pedicle."

In the human body all the organs are so anchored that they must follow the movements of the trunk. The intestines, through their peritoneal covering, are so well lubricated that they can move with the greatest ease and with less friction than in the best-oiled machinery, and torsion and strangulation would take place

inevitably on turning the body around if it were not for the mesenteric attachment (which, of course, has other important functions). Ovarian tumors can move with the same absence of friction, and, if they are attached by only a single small pedicle, the latter is liable to become twisted every time the patient turns round. It is only a question of favorable conditions or the reverse. Tumors that are firmly grasped by surrounding viscera will turn with them. Those that lie extremely to one side or the other will be carried round by the revolution of the body just as a ball held in the hand would, unless the person happened to turn round on one leg in such a way that the axis of motion fell within the tumor.

A woman engaged in housework turns round a great many times in the course of a day, as, for instance, in going from a kitchen table to the stove and back again. If she has a tumor such as we are considering, she may turn round hundreds or thousands of times without torsion taking place, simply because synchronous favorable conditions do not occur. Once in a while, however, her abdomen will be in just the right state of relaxation and the axis of revolution of her body will fall in just the proper place in the tumor for inertia to exert its power: her body turns but the tumor does not, and a partial or complete torsion takes place. If favorable conditions recur, many twists and complete strangulation may in time be produced. As most people have a preference for turning round always in the same direction, either to the right or left, the chances of untwisting do not equal those of twisting, though the former must occasionally occur.

Turning round horizontally, as in bed, may cause pedicle-twisting the same as perpendicular motion.

The same principle of inertia acting on the fœtus may explain the occasional twisting of the funis in utero.

218 HALE AVENUE.

COMPLETE LACERATION OF THE URETHRA.

WITH THE REPORT OF A CASE.

BY ARTHUR STERN, M. D.,

SURGEON TO THE ALEXIAN BROTHERS' HOSPITAL, ELIZABETH, N. J.

THERE are, according to Terrillon, three kinds of urethral laceration:

First. Interstitial laceration, which is very rare—six per cent. of all cases. In these a hæmatoma is formed in the corpus cavernosum, which becomes absorbed, or organized into scar tissue, or causes a necrosis of the urethra.

Second. The cavernous tissue and the urethra are torn to a greater or less degree.

Third. Complete laceration of the urethra, the ends of the urethra being completely separated. If urethrotomy is performed in these cases, the finger will enter a cavity filled with blood and urine.

The latter class, complete laceration of the urethra,

is comparatively rare. Kaufmann says that it is most frequently found in American and English hospitals, being quite unknown to some hospitals of Europe. He gives no reason for this singularity, but it is probably due to the increased vicissitudes of human activity growing out of the increasing use of complicated and delicate machinery with the attendant risk of accident. Frequent causes of urethral lacerations in general are falls on the perineum, kicks by horses, and bicycle and railroad accidents, the latter class involving for the most part fracture of the pelvis.

The seat of the complete laceration is commonly the bulbous part of the urethra. If the pelvis is fractured, the membranous portion is the affected part.

The symptoms of complete rupture of the urethra are few, but, taken together with the history of the case, are enough to make the diagnosis absolutely sure. They are, anuria, passing of blood instead of urine, and in most cases perineal swelling. If a catheter is introduced it will not enter the bladder, unless, indeed, it is introduced immediately after the accident. The patient always suffers more or less from shock.

The result of an injury of this latter kind depends largely on the treatment of it. If the true difficulty is not recognized, urinary infiltration, with the attendant sufferings of pyæmia, may follow; or, if fortune favors, perineal cellulitis with urinary fistula. If, however, the case is properly diagnosed, and surgical interference follows the accident, the result is nearly always favorable. In every case the treatment of complete rupture of the urethra should be by immediate external urethrotomy, even though it should be possible to introduce the catheter after the operation.

I submit a case.

George S., thirty-four years old, a native of Germany, consulted me on March 15, 1898, with reference to an urethral injury. His statement was that half an hour previously, while hanging clothes on a line, he fell from a ladder, on which he had been standing, and struck upon a fence near by, one of the pickets striking him midway between the testicles and the rectum. That shortly after he had tried to urinate, but had discharged instead quite a quantity of blood. He had walked a distance of about one mile to my office, was perspiring freely, and his face was pale and wore an anxious look. I at once sent him to the Alexian Brothers' Hospital, following him immediately. Upon my arrival I introduced a soft sterilized Nélaton catheter, and after a few fruitless trials had him prepared for external urethrotomy. After separating the superficial fascia, the finger entered a cavity which discharged about two ounces of bloody detritus, and in this cavity could be felt the guide which had been introduced. After considerable difficulty, the central portion of the urethra was discovered. A catheter *à demeure* was now introduced and left *in situ*. The ends of the urethra were not stitched over the catheter, as there was too great a laceration of the tissues. The external part of the catheter was stitched to the prepuce. The perineal wound was packed. Recovery was uneventful, with the exception of a balanitis, which the patient

developed during the latter part of the first week. Urotropin was administered twice a day. The perineal wound having closed completely—the urethra admitting 24 French size easily—the patient was discharged April 5, 1898.

Although external urethrotomy is one of the oldest, I might say, classical operations (seeing that Celsus, Hippocrates, the Arabian surgeon, Abul Kasim—end of the eleventh century in Cordova—and many French surgeons of the middle ages, including the great Pierre Franco, 1500-'62, used it frequently), it is only since the time of John Hunter, 1728-'93, that it has come into general use. Perhaps one of the reasons for this fact was the general aversion to producing scar tissue in the narrow channel of the urethra. W. Roser, 1817-'88, however, removed these fears by showing that as soon as the perineal cut begins to heal the scar produces a traction in the direction of the perineum, dilating the urethra at this point.

Lenander, in volume liv of the *Archiv für klinische Chirurgie*, published recently four cases of complete rupture of the urethra, elaborating in detail the anatomy, diagnosis, and prognosis of this injury. He recommends immediate operation, and, if possible, the stitching of the urethra over the catheter. He says, however, that it is sometimes impossible to stitch the urethra, as the tissues may be too brittle, or the distance between the two ends too great. He further says that the operation should be performed as soon as an attempt at catheterism fails.

Let me say once more that two things are needed for the treatment of complete laceration of the urethra—viz., early recognition and early operation.

218 EAST JESSA STREET.

THE COATED TONGUE.

By W. H. WEAVER, M.D.

CHICAGO,
PROFESSOR OF OTOLARYNGOLOGY, AND LARYNGOLOGY IN THE
CHICAGO EYE, EAR, NOSE, AND THROAT CLINIC.

THE fur on the dorsum of the tongue consists of epithelial cells, detached papillæ, considerable granular matter, organic and inorganic, all of which is kept in a state of fermentation by *Schizosaccharomyces fungi*. Millions of these micro-organisms may be found in a small particle of the coating. These fungi consist of micro-

cocci, sarcinae, bacteria, spirilla, innocent or infectious, if an infectious disease exists in proximity. If one member of a family has tuberculous consumption, tubercle bacilli may be found in the coating of the tongues of the other members. The micro-organisms thus found growing on the tongue are constantly washed into the stomach at every meal; thence are carried into the blood, probably through the lacteals. In this manner the blood may be supplied with so many germs that infection sooner or later takes place.

From a clinical standpoint this coating plays still another rôle, and should be looked upon as a comparative index to the purity or impurity of the blood. To say that it indicates or depends upon the condition of the stomach, or is simply of such and such a character in certain diseases, means nothing but the statement of a coincidence.

When the urine stands for a time in an unclean vessel, the solids, including both organic and inorganic constituents, are precipitated. The larger the amount of waste matter drawn from the blood and the denser the urine, the greater will be the amount of the precipitate. The same changes occur in all the other fluids, excretions, and secretions of the body when their temperature and normal conditions vary.

The salivary secretion is composed of certain normal constituents. Besides these normal constituents, which vary within certain limits, there are undoubtedly some abnormal elements which are carried out through the glands from the blood when it is surcharged with impurities. Now, when this abnormal saliva is thrown into the mouth and subjected to the action of the numerous micro-organisms of fermentation, more or less of the solid matters are thrown down and constitute a salivary precipitate, which lodges on the teeth and on the dorsum of the tongue, also on the gums and lips, which, in cases of typhoid fever, is known as sordes. This salivary precipitate can be recognized on the teeth, as it roughens their surface. It is easily removed by the use of the toothbrush. It covers the teeth as a whitish deposit which microscopically shows the different forms of micrococci and bacilli. Upon the tongue it is allowed to remain until it becomes very offensive, unless it is systematically removed by scraping. It undergoes fermentation very readily, and is usually of the same character, consequently communicating an odor to the breath which is recognized as being the same whenever it occurs. In Bright's disease, in diabetes, and in almost any disease in which the nutrition and excretory organs are disordered, the coating becomes very foul, and the fouler the tongue the more serious the condition of the patient, the more sluggish his excretory organs, and the more heavily loaded his blood is with toxins. In some diseases the odor of the breath, as well as the color and character of the coating, is peculiar to the disease, depending upon the peculiar forms of toxins with which the blood is charged.

Besides the systemic germ infection, it is a question if the highly offensive odor, noticeable in any case in which the tongue is heavily coated, has not also a considerably depressant effect on the nervous system, if not on the nutrition, acting much like a gaseous poison, as all the inspired air is laden with it as well as the expired air.

It has been my custom, when consulted regarding a foul breath or coated tongue, to advise the patient to procure a tongue scraper and diligently clean the tongue every morning as a part of the morning toilet, using after it a disinfectant mouth wash on the tongue and as a dentifrice. This method will remove the foulest odors from the breath. The same deposit appears on the tongue every morning and must be removed as often.

Every surgeon who has a coated tongue and wishes to be aseptic should look to this possible source of infection, for in coughing, sneezing, or even speaking, it is known that the breath takes with it particles of moisture from the mouth and throat. And every patient who is to have an operation about the mouth or throat should have his tongue cleaned and disinfected. Every fever patient should have his tongue systematically cleaned to remove just that much self-infection. And every person who wishes to be agreeable in the society of others should remove the foul coating on the tongue and with it the offensive odor of the breath.

29 STATE STREET.

Therapeutical Notes.

A Syrup for the Pertussislike Cough of Influenza.—

M. J. Bernard (*Gazette des hôpitaux*, 1898, No. 37; *Klinisch-therapeutische Wochenschrift*, April 9, 1899) gives the following formula:

℞ Bromoform,	} each 1 part;
Tincture of aconite,	
Alcohol	20 parts;
Syrup of codeine*	100 "
Syrup of Tolu	150 "

M. S.: A dessertspoonful three times a day.

Dionin: a New Morphine Derivative.—According to *Merck's Archives* for March, Ludwig Hesse (*Pharm. Centralh.*, xl, p. 5) describes dionin as the hydrochloride of morphine monoethyl ether or ethylmorphine. It occurs as a white, somewhat bitter, microcrystalline powder. Dionin appears to be very serviceable therapeutically, because it affords neutral solutions which may be advantageously employed subcutaneously. It is soluble in about seven parts of water, in about 1.4 part of alcohol, and in about twenty parts of syrup; while it is insoluble in ether and in chloroform. It is precipitated from its solutions by most of the alkaloidal reagents.

Dionin has been employed by O. Schröder and by J. Korte (*Therapeutische Monatshefte*, xiii, p. 33) in a score or so of phthisical cases, and from the results ob-

* Made by dissolving 1 part of codeine in 25 parts of alcohol, and adding 475 parts of syrup.

tained the authors believe that the preparation is of unquestionable value therapeutically. It appeared to be an excellent and reliable means in the treatment of cough in the early stages of pulmonary phthisis; and it is recommended instead of codeine and morphine in all cases of this disease that are not far advanced, as well as in chronic bronchitis, pulmonary emphysema, and bronchial asthma. Not a single failure was observed. The dyspnoea and cough were always relieved, the asthmatic attacks cut short, and expectoration favorably influenced. Compared with morphine, dionin is more mildly narcotic in action, has scarcely ever any noticeable effect on the digestive tract, and has no noteworthy by-effects. Compared with codeine, on the other hand, it is found to be more powerful generally, and more persistent in action; it affords better and quieter sleep, and increases expectoration considerably. As a general analgesic, dionin is not as reliable as morphine, but it may, nevertheless, be employed in chronic painful affections, either internally or subcutaneously; and as no tolerance or habit is apparently established, it may shield many patients from acquiring the morphine habit. Its particular sphere of action will, however, doubtless be in the treatment of coughs due to irritation, those of bronchitis of every origin, and in phthisical subjects, where it affords general quiet and good sleep, stimulates expectoration, and appears to exert also a beneficial influence on the night sweats.

Dionin may be given in doses of a quarter of a grain several times daily, or in one dose of half a grain in the evening, in solution, syrup, or pill.

For the Anorexia of Pregnancy.—The *Riforma medica* for April 23d attributes the following to Leyden:

℞ Calumba root,	℥ of each, 225 grains;
Powdered ginger root,	
Senna leaves	60 "
Boiling water	℥125 "

Make an infusion. A wineglassful may be taken before meals.

An Antiseptic and Cicatrizing Collodion.—The *Riforma medica* for April 21st gives the following:

℞ Mastic in tears	45 grains;
Dry balsam of Peru	15 "
Narcotine	15 "
Chloroform	75 "

M.

This preparation is said to be useful on account of its antiseptic and cicatrizing qualities.

The Treatment of Keratosis of the External Auditory Meatus with Dilute Sulphuric Acid.—Dr. Gomez de la Mata (*Oto-rino-laringologia española*, March), after pointing out the difference between ceruminous plugs, which are easily amenable to ordinary treatment, and those of cornal epithelium, which are very refractory, relates the case of a patient in whom such a concretion completely blocked the external auditory canal in its middle portion, deafness being complete on that side. The author applied daily to the man for nine days a probe covered with kid (chamois leather (")) moistened with sulphuric acid diluted with one and a half times its own weight of water. On the tenth day a large portion broke down and became loosened, and in fourteen days the plug was perforated. The acid, however, caused some burning pain to the ear and set up a suppurative action, which loosened the ring of epithelium, so that it came away with alkaline syringing.

The membrana tympani was found normal, and hearing was restored. We imagine that considerable care must be exercised in the use of this doubtless efficient remedy, lest danger accrue to the membrane.

Tincture of Iodine in Acute Gastro-enteritis.—M. Bizine (*Indépendance médicale*, December 28th) recommends the following in cholera infantum and ordinary diarrhoea:

℞ Emulsion of castor oil	2,500 grains;
Essence of peppermint	3 drops;
Essence of cloves	5 "
Tincture of iodine	10 "
Chloroform	2 "

M. A teaspoonful to be taken hourly. The mixture should be kept on ice to prevent decomposition.

The foregoing quantity of the mixture usually suffices to effect a cure. Sometimes, however, a slight flux remains, in which case the author gives twice daily in a little water one of the following powders:

℞ Iodized starch	11½ grains.
------------------------	-------------

To be divided into six powders.

In the case of an adult, M. Bizine employs the mixture as follows:

℞ Emulsion of castor oil	2,500 grains;
Essence of peppermint	5 drops;
Essence of cloves	7 "
Tincture of iodine	15 "
Chloroform	5 "

M. A tablespoonful to be taken hourly.

The starch powders are thus prepared:

℞ Iodized starch	9 grains
------------------------	----------

in each powder. One powder may be given every four hours.

Orthoform as a Remedy for Toothache.—Hildbrant (*Medical Press and Circular*, December 21, 1898; *Therapeutic Gazette*, April, 1899) states that orthoform produces immediate and complete relief from the severe pain due to inflammation of the pulp in a decayed tooth. A bit of cotton soaked in an alcoholic solution (strength not stated) is to be inserted in the cavity.

Gnëpin's Vesicating Fluid.—The *Progrès médical* for April 8th gives the following:

℞ Concentrated ammonia	1 part;
Camphorated oil	2 parts.

M. A pledget of cotton wool of the size of the intended blister is to be moistened with this oil and applied for fifteen minutes to the skin in the place desired. Vesication is rapid.

For Fissures of the Tongue.—The *Riforma medica* for April 10th gives the following formula:

℞ Carbolic acid	324 grains;
Tincture of iodine	25 "
Glycerin	225 "

M. For local application.

The Treatment of Infective Infantile Diarrhoea.—The *Journal des praticiens* for April 22d recommends the following:

℞ Eau sucrée	300 grains;
Wine of opium	from 4 to 2 drops;
Dilute hydrochloric acid	2 drops.

M.

To be given in one dose. It may be repeated several times a day, according to the indications [remembering that children are especially susceptible to opium].

THE
NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 13, 1899.

PRIVATE HOSPITALS AND THE PUBLIC FUNDS.

THE municipality of New York provides generously for its sick and injured poor. It is true that most of the large hospitals are private, in the sense that they are not owned, managed, or wholly maintained as city institutions. Some of them, however, manage to obtain a good deal of money from the city to aid them in their charitable work. This is understood by the community in a general way, but we think it is not commonly known that in some instances money given to a hospital to endow a bed goes toward defraying the general expenses of the institution, and then virtually a second endowment of that bed is demanded of the city, and often obtained.

The *Mail and Express* recently made some striking quotations from a report prepared by the commissioners of accounts of an examination of the books of the New York Post-graduate Medical School and Hospital. The commissioners say in their report: "It appears to be the practice in all hospitals of this city to consider the endowment of a bed as a donation to the hospital, instead of being for the benefit of some poor patient. Notwithstanding the endowment fund, the city is charged by the hospital for the treatment of the patient as a free patient, and, therefore, the hospital is paid twice." The commissioners go on to say that early in the year 1898 they made a similar statement in their report on the New York Society for the Relief of the Ruptured and Crippled, and they now suggest to the comptroller that an opinion be obtained from the corporation counsel as to the legality of such charges against the city.

According to the *Mail and Express's* article, the sum of forty cents is allowed by law to the Mount Sinai Hospital, and that of a dollar to the Polyclinic and Homoeopathic hospitals, for each day of free treatment of a patient in the wards. By multiplying these daily allowances respectively by the number of days of free treatment given by the New York Post-graduate Medical School and Hospital during the year 1898, and subtracting the products from the sum of \$25,000 allowed that institution out of the public funds, they find that the excess over the amount really required to provide the 11,236 days of free treatment reported

was \$20,505.60 on the forty-cents-a-day basis, and \$13,764.00 on the dollar-a-day basis.

As regards this particular institution, we understand that the facts are as follows: At two different times special appropriations have been made by the legislature for its benefit. One of them was of thirty-eight cents *per diem* for each infant treated in the babies' wards. The other was of a lump sum of \$25,000 per annum for the general use of the hospital, without specific mention of the amount of free treatment to be given. These enactments are not mandatory, but their execution is left to the discretion of the board of estimate and apportionment of the city. Sworn statements as to the number of babies treated are submitted to the comptroller by the hospital every three months, and on the strength of these statements the city allows the hospital \$10,000 annually. Now, with very few exceptions, every bed in the babies' wards is either endowed in perpetuity or supported by private annual contributions. This is how the hospital is "paid twice."

The additional allowance of \$25,000 is granted on the strength of testimony going to show the immense amount of charitable work done by the institution. But many of the beds outside of the babies' wards are endowed or maintained from year to year by individual contributions, and two years ago this consideration led one of the directors, Dr. Kelsey, who was also at that time a professor in the school, to dissent before the board of estimate and apportionment from the contention that the amount of charitable work done by the hospital was such as to entitle it to the appropriation. Shortly afterward he was ousted from his professorship for the reason, implied if not expressly stated, that he had shown a lack of loyalty to the institution in declining to join in its representations before the board. The commissioners of accounts seem now to have arrived at conclusions which justify Dr. Kelsey's course. Practically the hospital is "paid twice" for much of its work.

THE OPEN METHOD OF ADMINISTERING NITROUS OXIDE.

A VERY interesting contribution to our methods of inducing anesthesia, and one which, if it is proved to possess all the advantages alleged for it, is likely to prove of great service, was, according to the *Clinical Journal* for April 19th, made by Dr. Flux at a recent meeting of the Society of Anesthetists in London. Dr. Flux discards the closed mouthpiece and uses an inhaler closely fitting the patient's face, but wide open at the top, into which the gas is allowed to fall from any simple delivery apparatus. The gas naturally falls by

its own weight and has no tendency to escape upward, while the accurate adaptation of the inhaler to the face prevents its leakage downward. By this method of administration, which Dr. Flux had employed three hundred and fifty times, he affirms that the patient experiences absolutely no discomfort, since he is subjected neither to breathing into an air-excluding face-piece nor to the high pressure at which the gas issues from the cylinder into the inhaler. It is inhaled comfortably at the ordinary atmospheric pressure. Free access of air to the patient is obtained, and the gas is admitted into the inspired air in place of the air being admitted to the inspired gas, as is the case in the ordinary closed method. The gas only needs to be allowed to flow during inspiration, and, when once anaesthesia has been induced, it can be kept up indefinitely by allowing the patient an occasional breath of gas. Moreover, as the anaesthetist has the gas under complete control, he can raise and lower the degree of anaesthesia as often and as quickly as desired.

Dr. Flux at first used some textile fabric, such as a napkin, folded into an open cone; but he has since had two forms of inhaler made out of clear thin celluloid which is light, transparent, pliable, non-absorbent, and easily cleansed. One form is in the shape of a cone open at both ends, for use on patients in the recumbent posture; the other is open at the top and on one side for a patient sitting down. A rubber tube capable of inflation round the face aperture insures accurate adaptation in either form.

From seven to eight gallons of gas are required to induce anaesthesia in an adult, and from three to four gallons are required for each additional minute during which anaesthesia is to be maintained.

Dr. Flux thus describes the effect of this method of administration upon the patient: "After the first few breaths the agitation caused by apprehension subsides; the patient assumes a sleepy appearance, and, in from five to ten seconds, is unconscious; the breathing becomes steady and tranquil, and by the end of from fifty to eighty seconds the patient is completely anaesthetic, the only visible alteration being a change from a condition of wakefulness to one of sleep, which is so tranquil that onlookers who have not previously seen this method employed can hardly believe that the patient is ready for operation.

"No excitement, stertor, lividity, or convulsive movement, or any sign of asphyxia, occurs throughout the administration and resulting anaesthesia; in fact, the whole proceeding is characterized by extreme placidity. In no case has it been necessary to use force to restrain the patient either during or after the exhibi-

tion of the anaesthetic. Even when administering with unsuitable or improvised inhalers, or under adverse or previously untried conditions, the results have been almost uniformly satisfactory."

In the discussion which ensued, Mr. Baldwin and Mr. Carter Braine, both of whom had seen Dr. Flux administer gas by this method, and the latter of whom had had it tried upon himself, bore testimony to the efficiency of the method. The latter gentleman stated that so insensible was the change when he saw Dr. Flux administer the gas to patients for operation at the Dental Hospital of London that, although he watched the patients very carefully, he was unable to tell when they were anaesthetized. They appeared simply to drop off into a normal sleep. For himself, he had taken gas many times, but never so comfortably as in this instance. He breathed perfectly naturally and did not seem to be taking gas.

The testimony given was in favor of the open administration of nitrous-oxide gas, and Dr. Flux replied very satisfactorily to the few critical remarks based upon theoretical objections. The method, therefore, seems well worthy of an extended trial, as, if this procedure fulfills all it promises, it will open up a much wider field for the use of this comparatively safe anaesthetic.

THE LICENSE TO PRACTISE IN ILLINOIS.

UNDER the law which goes into effect, as we understand, on the 1st of July, the State board of health, which will continue to be charged with the function of passing upon the qualifications of applicants, is allowed to exercise its own discretion as to subjecting graduates of recognized Illinois schools to an examination. We learn, however, that in all probability the board will decide that all candidates, without exception, must pass the examination. This, we think, is by all means the most commendable course for the board to pursue. It would do away at once with any suspicion that the board was acting especially in the interest of the Illinois schools. Such a suspicion, we feel sure, would in any case be unfounded, but it might be entertained and made to serve the opponents of the board's work.

The board has not yet adopted any rules relative to the examination, and probably will not do so until its regular quarterly meeting, on July 11th, but our information is that it is likely to be in writing and in the subjects of anatomy, physiology, chemistry, materia medica and therapeutics, pathology and bacteriology, surgery, theory and practice of medicine, obstetrics, gynaecology, and hygiene and medical jurisprudence. All applicants for the examination must be graduates of

medical colleges in good standing, as may be determined by the board. Probably the first examination will be held in Chicago, beginning on July 26th and lasting for four days. It is announced that applications for the examination should not be made before July 1st.

It will be remembered that under the law now in force only applicants who are not graduates are necessarily subjected to examination. There can be no doubt, therefore, that the new law, in conjunction with recent legislation looking to the suppression of diploma mills and the prevention of successors to those suppressed, will prove powerful to put the regulation of practice in the State on a thoroughly satisfactory basis.

A DREAM CURE.

SEARCHING abroad for knowledge of what is going on in our own town, we find the Quebec *Revue médicale* for April 12th citing from the *Progrès médical* the description of a method of treating nervous excitability and kindred ailments by the induction of pleasing dreams. Dr. J. Leonard Corning uses a kind of pliable leather nightcap enveloping the entire head except the face. To the carapices are attached the rubber tubes of an Edison's phonograph. The patient, having donned the cap, lies down, preferably on his back, on a divan in a sort of tent, which incloses him entirely, the foot having a white screen as for a magic lantern. Behind the patient's head is a stereopticon which throws varied chromatic images on the white screen at the foot, and at the same time murmuring sounds are transmitted to the ears by the phonograph. Under this combined action of kaleidoscopic visual influences and the snurrus of the phonograph, which, no doubt, acts similarly to the "gentle murmurs of the rippling brook, or hum of insects in the sleepy air," it is said that a sense of pleasing fatigue takes possession of the patient, and that in the waking dream state which follows pleasant dreams ensue. Dr. Corning cites cases in which not only was sleep induced and the irritability calmed, but the bodily weight was increased under the influence of this treatment. The vast strides which have been made in recent years in our knowledge of the psychical effects of various remedies and their relations to the physical processes of the body should check any hasty skepticism, or rather should stimulate that true skepticism which puts all things susceptible of demonstration to experimental test, and our neurologists may well investigate what truth there is in this mode of treatment for nervous and mental troubles.

THE TUBERCULIN TEST FOR BOVINE TUBERCULOSIS.

A STRIKING example of the value of this test has recently, according to the *Lancet* for April 15th, been forthcoming in England. Her Majesty the Queen had on her home farm at Windsor a herd of forty cows, all apparently in perfect health and condition. These were tested with the tuberculin test, and in thirty-four of them the temperature rose in the typical fashion to about 101° F. Only five of the cows were apparently healthy. The whole herd was therefore ordered by her Majesty to

be killed, and the carcasses were examined by the Royal College of Veterinary Surgeons. Of the thirty-four whose temperature rose above 101° F., thirty-three were found to be tuberculous. The remaining animal was not tuberculous, but had a diseased uterus. The rise in this case was sudden and did not occur until after the twelfth hour. Of four cows which did not react, three were found to be free from tubercle and the fourth had one small caseous gland, in which tubercle bacilli were found. The two remaining cows, which had been classed "doubtful," were both found to be tuberculous. The new dairy herd at Windsor is to be formed only from cows which have been tested by tuberculin and found not to react. This story is satisfactory from two points of view: as showing, first, the value of the tuberculin test, and, secondly, as the Prince of Wales has always done, how the royal family of England lend the weight of their influence and example to all well-approved developments of sanitary progress and public welfare.

SKIAGRAPHY IN LEGAL MEDICINE.

THE *Revue médicale* for April 19th records the remarkable case of a coachman who was accused of having attempted to kill his mistress by firing a revolver at her head. He then turned the weapon on himself and shot himself in the breast. The bullets were extracted and the wounded people were cured. On being arrested, the coachman alleged that the weapon had gone off accidentally and that he had had no intention of harming his mistress. Only one ball had been found in the woman's head, near the ear, and the course taken by it rendered the hypothesis of accident plausible, in consequence of which the coachman was sentenced to only three months' imprisonment for serious injury caused by negligence. The *juge d'instruction*, however, ordered a skiagraphic examination to be made, which revealed that a second shot had been fired, and that this ball had lodged below the first. The course taken by this projectile, says the *Revue*, left no doubt that murder had been attempted. While the value of the means which demonstrated the presence of the second shot can not be gainsaid, we are not told whether there was or was not also a second wound of entrance. It seems incredible that if two shots had entered the body it should have been necessary to employ the skiagraph to prove that fact, upon which the assumption of intentional as against accidental wounding seems to have depended, although that apparatus might render signal service in locating the bullet.

A NEW SYMPTOM FOR THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

DR. MURAT (*Gazette hebdomadaire de médecine et de chirurgie*, March 5th) calls attention to a subjective symptom which he has found very frequently present in the subjects of incipient tuberculosis. As it causes no distress, patients, as a rule, are unaware of it until their attention is directed to it. It consists of a sensible vibration in the affected apex on loud speaking. Sometimes the patient instinctively tries to diminish this vibration by pressing the corresponding arm against the body. This symptom is a logical consequence of the induration of the lung tissue, and is akin in its nature to bronchophony, which it often precedes, however, as Dr. Murat is able to aver from his own observations. If a patient in whom an early phthisical condition is suspected is

instructed to make deep local expirations, and his attention is directed to this point, he will generally be able to recognize the vibration on the affected side, as though the tuberculous lung were in relation with the larynx, while no such sensation is perceptible on the sound side. A thorough investigation of this point would, if it substantiates Dr. Murat's opinion, place us in possession of a very valuable aid to the early diagnosis of pulmonary tuberculosis.

SOCIETY CONFEDERATION IN CHICAGO.

MEASURES tending to a closer organization of the medical profession are always favorable to its efforts and to its influence. We are glad, therefore, to learn from the May number of our excellent Chicago contemporary, *Medicine*, that most of the medical societies of that city have been practically merged in the Chicago Medical Society, although many of them preserve the control of their own affairs.

DISAGREEABLE EFFECTS FROM ORTHOFORM.

INASMUCH as orthoform has been said to be harmless, certain reports made at a recent meeting of the Paris Hospitals Medical Society (*Gazette hebdomadaire de médecine et de chirurgie*, April 20th) seem deserving of notice. M. Brocq stated that he had used it in solution and in the form of an ointment in the treatment of pruritus. In solution, he had found it irritating; in the form of a one-to-twenty ointment it was very efficacious in allaying itching, but in the course of two or three days there were always artificial eruptions which were themselves extremely itchy and sometimes protracted. He had observed very extensive cutaneous affections attributable to it and associated with general poisoning. M. Thibierge referred to the fact that Epstein also had seen general poisoning from the subcutaneous use of orthoform in conjunction with calomel, and reported that the punctures were extremely painful.

SPASTIC SPINAL PARALYSIS DUE TO INFLUENZA.

MYELITIS seems to be a far rarer sequel of influenza than encephalitis. Dr. L. Michaelis (*Deutsche medizinische Wochenschrift*, 1899, No. 7; *Wiener medizinische Blätter*, April 20th) states that not more than six cases have been reported. He records one characterized by paresis and spastic contractures of the legs, ending in recovery in about six weeks. The anatomical lesion, he remarks, can not have been severe; it was probably circumscribed, if, indeed, the symptoms were not due to a purely functional disturbance of toxic origin.

MAMMARY HYPERTROPHY AND UTERINE ATROPHY.

APART from pregnancy, the relations between the mammary glands and the uterine and ovarian functions are not very clearly defined. Dr. E. Frankel, of Breslau (*Deutsche medizinische Wochenschrift*, 1898, No. 25; *Centralblatt für Gynäkologie*, April 29, 1899), relates the case of a virgin, thirty years old, in whom great hypertrophy of the breasts had come on within four or five months, although they had been moderately enlarged for six months before. From the age of twenty-two to that of twenty-eight she had had amenorrhœa, and then the menses returned. The author is inclined to think that the mammary hypertrophy was connected with the

amenorrhœa and with a slight atrophy of the uterus, being occasioned by a sort of vicarious hyperæmia.

PAINFUL PARALYSIS IN CHILDREN.

SUBLUXATION from an unrecognized cause is not a very rare condition in children, and it may often be reduced by accident. This may or may not explain the sudden painful paralysis of a limb which M. Bertraud (cited in the *British Medical Journal* for April 22d) has recently made the subject of a thesis. It is generally an upper extremity that is affected. The least movement is painful, but there is no impairment of sensibility. Abatement usually follows within a few days. Passive motion is then practicable, and recovery soon ensues.

PASTEUR AND THE TOWN OF LILLE.

THE fact that Pasteur in the early part of his career was professor of chemistry and dean of the faculty of science at Lille renders that city an especially suitable place in which to commemorate his memory, as has been recently done by the unveiling of a monument to him there, and the opening of a handsome Pasteur institute, liberally subsidized by the local authorities. Dr. Calmette is the director, with a staff of nine officials and fourteen servants. The Pasteur institute of Lille, therefore, gives promise of being the centre of great and important future researches.

NEW JOURNALS.

AMONG the new American journals that have reached us recently are the *Jeffersonian*, published monthly by the undergraduates of the Jefferson Medical College, Philadelphia, and Dr. Karl von Ruck's quarterly, the *Journal of Tuberculosis*, published in Asheville, North Carolina. Both are handsome in appearance and promise to be useful additions to our periodical literature.

THE HEALTH OF PROFESSOR AUSTIN FLINT.

OUR readers will be glad to learn that as we go to press the news of Dr. Flint is that he is better and now almost certain to recover from his severe attack of pneumonia, which, we understand, occurred as a sequel of influenza.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 6, 1899:

DISEASES.	Week ending Apr. 29.		Week ending May 6.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	12	8	16	6
Scarlet fever.....	226	17	294	17
Cerebro-spinal meningitis.....	0	16	0	8
Measles.....	206	12	112	14
Diphtheria.....	25	2	174	28
Croup.....	8	0	4	3
Tuberculosis.....	170	148	165	192
Small pox.....	4	0	9	0
Chicken pox.....	50	0	14	0

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general for the week ending May 6, 1899:

Small-pox—United States.

Mobile, Ala.	Apr. 29.	1 case.	
Los Angeles, Cal.	Apr. 22-29.	1 "	1 death.
Washington, D. C.	Apr. 28.	1 "	
Jacksonville, Fla.	Apr. 23-30.	9 cases.	
Chicago, Ill.	Apr. 17-29.	2 "	
New Orleans, La.	Apr. 22-29.	16 "	1 "
Shreveport, La.	Apr. 22-29.	2 "	
Baltimore, Md.	Apr. 30-May 2.	2 "	
Boston, Mass.	Apr. 17-26.	9 "	
Michigan.	Apr. 22-29.	Present at two places (Benton Harbor and Kalamazoo Township).	
Las Cruces, New Mexico.	Apr. 27.	Many new cases.	
Buffalo, N. Y.	Apr. 29.	1 case.	
Cincinnati, Ohio.	Apr. 21-28.	15 cases.	2 deaths.
Erie, Pa.	May 2.	1 case.	
Pittsburgh, Pa.	Apr. 22-29.	1 "	
Del Rio, Texas.	Apr. 18.	1 "	
Galveston, Texas.	Apr. 15-22.	8 cases.	
Newport News, Va.	Apr. 23-May 1.	4 "	
Norfolk, Va.	Apr. 23-May 3.	4 "	1 death.
Portsmouth, Va.	Apr. 23-May 3.	15 "	
Spokane, Wash.	Apr. 22-29.	2 "	

Small-pox—Foreign.

Rio de Janeiro, Brazil.	Mar. 11-24.	11 deaths.	
Hongkong, China.	Mar. 11-25.	4 cases.	3 "
Barraquilla, Colombia.	Apr. 1-8.	2 "	
London, England.	Mar. 8-15.	3 "	
Tamsui, Formosa.	Feb. 10-Mar. 10.	88 "	2 "
Athens, Greece.	Apr. 8-15.	16 "	5 "
Bombay, India.	Mar. 28-Apr. 4.	10 "	
Calcutta, India.	Mar. 18-25.	6 "	
Madras, India.	Mar. 11-25.	1 death.	
Seoul, Korea.	Mar. 11-18.	Small-pox present.	
Chihuahua, Mexico.	Apr. 8-22.	3 deaths.	
Mexico, Mexico.	Apr. 16-23.	16 cases.	5 "
Bluefields, Nicaragua.	Apr. 15-22.	1 case.	
St. Petersburg, Russia.	Apr. 1-15.	30 cases.	8 "
Constantinople, Turkey.	Apr. 10-17.	10 "	
Smyrna, Turkey.	Apr. 8-15.	1 death.	

Yellow Fever.

Rio de Janeiro, Brazil.	Mar. 10-24.	112 cases.	88 deaths.
-------------------------	-------------	------------	------------

Cholera.

Bombay, India.	Mar. 28-Apr. 4.	3 deaths.	
Calcutta, India.	Mar. 18-25.	17 "	

Plague.

Tamsui, Formosa.	Feb. 10-Mar. 10.	201 cases.	123 deaths.
Madras, India.	Apr. 18-24.	1 death.	

The Long Island College Hospital.—Professor A. J. C. Skene, M. D., has been appointed emeritus professor of gynecology. The chairs of obstetrics and gynecology have been combined, under Professor Charles Jewett, M. D. The department of bacteriology has been added to that of pathology, under Professor J. M. Van Cott, M. D. The department of histology has been assigned to Professor W. W. Browning, of the chair of anatomy. The following appointments have been made: Henry H. Morton, M. D., clinical professor of genito-urinary diseases; Robert L. Dickinson, M. D., assistant professor of obstetrics; Gordon R. Hall, M. D., assistant professor of the practice of medicine; George McNaughton, M. D., and Ernest Palmer, M. D., lecturers on gynecology; Wilbur H. Seymour, M. D., lecturer on histology and instructor in pathology; C. E. Gunther, M. D., instructor in clinical medicine; Clarence R. Hyde, M. D., H. P. de Forest, M. D., and Jarvis S. Wight, Jr., M. D., instructors in the obstetric manikin; Homer E. Fraser, M. D., assistant to the chair of genito-urinary diseases;

Briton H. Richardson, M. D., assistant to the chair of anatomy; Walter Truslow, M. D., William S. Hubbard, M. D., and Joseph O. Kilgariff, M. D., assistants to the chair of orthopaedics; John C. Cardwell, M. D., demonstrator of physiology; and Sewall Matheson, M. D., and Daniel C. Mangan, M. D., assistants to the chair of chemistry and toxicology. A summer course has been established, to begin on May 18th and to close about August 1st. This will consist of recitations and hospital clinics.

Tuberculous Diseases in Havana.—From a review in the *Habana Medica* for April, on Dr. Antonio Gordon y Acosta's book *La Tuberculosis en la Habana desde el Punto de Vista Social y Económico*, we learn that in the quinquennium 1892-'98, 11,970 persons died of phthisical diseases.

The Sportsmanlike Spirit as a Factor in Evolutionary Progress.—Professor Hardie, at the Edinburgh University spring graduation, concluded his address to the new graduates by pleading for a little more of the spirit of sport in the serious business of life; that the same kind of resolution, self-sacrifice, and energy should prevail in both; and that training and good condition, soundness in mind and body, should be looked on as no less essential in the one than in the other. He quoted finally the words of the Harrow song:

"God give us bases to guard or beleaguer,
Games to play out whether earnest or fun,
Fights for the fearless and goals for the eager,
Twenty and thirty and forty years on!"

The Gouverneur Hospital.—We are informed that Dr. Henry M. Silver has been transferred from the medical to the surgical visiting staff of Gouverneur Hospital.

The Buffalo Academy of Medicine.—At the last meeting of the Section in Medicine, on Tuesday evening, the 9th inst., Dr. Joseph W. Grosvenor read a paper on *The Use of Alcohol in the Treatment of Diseases*, which was discussed by Dr. Henry R. Hopkins, Dr. A. L. Benedict, Dr. E. L. Frost, Dr. Sydney A. Dunham, and Dr. J. Grafton Jones.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 6th inst., Dr. J. B. Ross presented the conclusion of his paper on *Antitoxine, Therapeutically Useless and Biologically Faulty*, and Dr. Joseph Grindon presented a case of scleroderma.

The Richmond Academy of Medicine and Surgery.—At the last meeting, on Tuesday evening, the 9th inst., the subject for discussion was *Sarcoma of the Kidney*, which was opened by Dr. J. M. Winfree.

Changes of Address.—Dr. Charles A. Clinton, to No. 112 West One Hundred and Thirty-first Street, New York; Dr. Andrew F. Currier, to No. 113 East Fortieth Street, New York; Dr. J. Carlisle de Vries, to No. 1309 L Street, N. W., Washington, D. C.; Dr. Allen Pitch, to No. 38 West Fifty-sixth Street, New York; Dr. Leopold Harris, to No. 66 Columbia Street, New York; Dr. Justin Herold, to No. 325 East Eighty-seventh Street, New York; Dr. C. N. Holmes, to No. 402 West One Hundred and Forty-fifth Street, New York; Dr. E. P. Livingston, to No. 460 West One Hundred and Fifty-second Street, New York; Dr. Heinrich Stern, to No. 56 East Seventy-sixth Street, New York.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 29 to May 6, 1899:*

BAXISTER, WILLIAM B., Captain and Assistant Surgeon, is relieved from further duty at Fort Keogh, Montana.

BEVANS, JAMES L., Acting Assistant Surgeon, United States Army, is relieved from further duty at St. Louis, and will proceed to San Francisco and report to the commanding general, Department of California, for duty.

FURBUSH, CHARLES L., Acting Assistant Surgeon, United States Army, is relieved from further duty on the hospital ship *Missouri* and will proceed to Havana and report to the commanding general, Division of Cuba, for duty.

KENNEDY, JAMES M., Captain and Assistant Surgeon, is relieved from further duty pertaining to the muster-out of troops at Augusta, Georgia, and will proceed to the Presidio of San Francisco and report to the commanding officer, Fourth Cavalry, for duty, to accompany that regiment to Manila.

OWEN, WILLIAM O., Major and Surgeon, United States Volunteers, will proceed to St. Louis and assume the duties of attending surgeon and examiner of recruits, reporting to the commanding general, Department of the Missouri.

SHAW, HENRY A., Captain and Assistant Surgeon, is relieved from further duty at Savannah, and also from duty and station at Fort Snelling, Minnesota, and will proceed to San Francisco and report to the commanding officer of the general hospital at that place for duty.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending May 6, 1899:*

BRAISTED, W. C., Passed Assistant Surgeon. Detached from the Naval Hospital, Newport, Rhode Island, and placed on waiting orders for sea duty.

BYRNES, J. C., Surgeon. Detached from the Norfolk Navy Yard and ordered to the *Massachusetts*.

COSTIGAN, G. D., Assistant Surgeon. Detached from the *Indiana* and ordered to the Naval Hospital, Chelsea, Massachusetts.

DICKSON, S. H., Surgeon. Detached from the *Massachusetts* and ordered home to await orders.

DRENNAN, M. C., Medical Inspector. Ordered to additional duty at the marine recruiting rendezvous, Philadelphia.

EDGAR, J. M., Surgeon. Detached from the *Richmond* and ordered to the *Amphitrite*.

ELLIOTT, M. S., Assistant Surgeon. Detached from the *Texas* and ordered home to await orders.

FITZSIMMONS, P., Medical Inspector. Detached from the *Brooklyn* and ordered to the *New York* as fleet surgeon of the North Atlantic Squadron.

GARTON, W. M., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the *Annapolis*.

GATEWOOD, J. D., Surgeon. Ordered to the Bureau of Medicine and Surgery for temporary duty.

GINON, A. L., Medical Director, retired. Granted leave of absence for one year, with permission to leave the United States.

GRAYVATT, C. F., Medical Inspector. Detached from the *New York* and from duty as fleet surgeon of the

North Atlantic Squadron and ordered home to await orders.

HARMON, C. E. H., Surgeon. Detached from the *Amphitrite* and ordered to the *Brooklyn*.

LUMSDEN, G. P., Surgeon. Detached from the *Franklin* and ordered to the *Richmond*.

OLCOTT, F. W., Passed Assistant Surgeon. Ordered to the *Texas*.

PALMER, S. B., Assistant Surgeon. Detached from the *Annapolis* and ordered home.

PAYNE, J. H., Assistant Surgeon. Detached from the Naval Hospital, Chelsea, Massachusetts, and ordered to the *Indiana*.

SNYDER, J. J., Assistant Surgeon. Detached from the *Wabash* and ordered to the Naval Hospital, Newport, Rhode Island.

STEELE, J. M., Surgeon. Ordered to temporary duty at the recruiting rendezvous, Baltimore.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending May 4, 1899:*

WHEELER, W. A., Surgeon. Department letter of April 21, 1899, granting Surgeon Wheeler twenty-seven days' leave of absence from June 4, 1899, amended so that the said leave shall take effect from May 5, 1899. Department letter of April 20, 1899, accepting the resignation of Surgeon Wheeler, to take effect from June 30, 1899, amended so that said resignation shall take effect May 31, 1899.

BROOKS, S. D., Surgeon. Relieved from duty as member of board convened to meet at San Francisco, California, May 2, 1899, for the examination of candidates for appointment as assistant surgeon in the service.

MAGRIDER, G. M., Passed Assistant Surgeon. Granted leave of absence for fourteen days.

PERRY, T. B., Passed Assistant Surgeon. Detailed as a member of the board convened to meet at San Francisco, California, May 2, 1899, for the examination of candidates for appointment as assistant surgeon in the service.

WERTENBAKER, C. P., Passed Assistant Surgeon. To rejoin station at Wilmington, North Carolina.

HASTINGS, HILL, Assistant Surgeon. Relieved from duty at Seattle, Washington, and directed to proceed to Astoria, Oregon, for the purpose of establishing a United States quarantine station at or near that point.

RUSSELL, H. C., Assistant Surgeon. Relieved from duty at Louisville, Kentucky, and directed to proceed to Cairo, Illinois, and assume temporary command of service.

PARKER, H. B., Assistant Surgeon. Detached as quarantine officer of the port of Santiago, Cuba.

LEWIS, L. L., Assistant Surgeon. To proceed to Seattle, Washington, and assume command of service.

ANDERSON, J. E., Assistant Surgeon. Granted thirty days' extension of sick leave from May 1, 1899.

FRICKS, L. D., Assistant Surgeon. Relieved from duty on United States transport *S. F. Cook* and directed to assume temporary command of service at Savannah, Georgia.

KEIR, J. W., Assistant Surgeon. To proceed to the San Francisco Quarantine Station and report to the commanding officer for temporary duty.

SCOTT, E. B., Hospital Steward. To report to acting assistant surgeon in charge, Savannah Quarantine, for duty and assignment to quarters.

COMFORT, N. C., Hospital Steward. Relieved from duty at Cincinnati, Ohio, and directed to proceed to Louisville, Kentucky, and report to commanding officer for duty and assignment to quarters.

Society Meetings for the Coming Week:

MONDAY, May 15th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, May 16th: Illinois State Medical Society (first day—Cairo); Missouri State Medical Association (first day—Joplin); Pennsylvania State Medical Society (first day—Johnstown); New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Chemung (annual), Essex (annual—Elizabethtown), Kings, Livingston (annual), Schoharie (annual), St. Lawrence (annual), Washington (annual), and Westchester (annual—White Plains), New York; Hampden, Massachusetts, District Medical Society (annual—Springfield); Baltimore Academy of Medicine.

WEDNESDAY, May 17th: Kentucky State Medical Society (first day—Louisville); Illinois State Medical Society (second day); Missouri State Medical Association (second day); Pennsylvania State Medical Society (second day); Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, May 18th: Kentucky State Medical Society (second day); Illinois State Medical Society (third day); Missouri State Medical Association (third day); Pennsylvania State Medical Society (third day); New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

FRIDAY, May 19th: Kentucky State Medical Society (third day); New York Academy of Medicine (Section in Orthopaedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

Births, Marriages, and Deaths.

Married.

DOUGLAS—CHRISTIE.—In New York, on Wednesday, May 3d, Mr. Henry Percy Douglas and Miss Katharine Ross Christie, daughter of Dr. Thomas H. L. Christie.

HOLMES—LENKE.—In Newport, Rhode Island, on Saturday, April 29th, Dr. Kirk W. Holmes, of Cos Cob, Connecticut, and Miss Hedwig L. Lenke.

KENYON—QUIMBY.—In Titusville, Pennsylvania, on Wednesday, May 3d, Dr. George H. Kenyon, of

Providence, Rhode Island, and Miss Emma May Quimby.

SWARTZLANDER—EVANS.—In Pottstown, Pennsylvania, on Thursday, May 4th, Dr. Frank B. Swartzlander, Jr., of Doylestown, Pennsylvania, and Miss Florence R. Evans.

WOLFE—GOODWIN.—In Thomaston, Connecticut, on Tuesday, May 2d, Mr. Francis J. Wolfe and Miss Grace Goodwin, daughter of Dr. Ralph Schuyler Goodwin.

Died.

BORDIS.—In Assumption, Louisiana, on Monday, May 1st, Dr. Gaston C. Bordis, in the fifty-second year of his age.

BOWSER.—In Brooklyn, on Thursday, May 4th, Dr. Willard Parker Bowser, in the fiftieth year of his age.

FINCH.—In Fort Ann, New York, on Saturday, May 6th, Dr. Sarah Finch, aged sixty-one years.

GODDING.—In Washington, on Saturday, May 6th, Dr. William Whitney Godding, in the sixty-ninth year of his age.

KIRKBRIDE.—In Philadelphia, on Thursday, May 4th, Dr. Joseph John Kirkbride, in the forty-eighth year of his age.

RUSSELL.—In Barre, Massachusetts, on Saturday, May 6th, Dr. W. L. Russell, in the one hundredth year of his age.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XVIII.

RIGHT TO COMPENSATION; FAILURE TO BENEFIT PATIENT
NO NECESSARY BAR TO RECOVERY OF COMPENSATION.

(Continued from page 647.)

Rights under Contract "No Cure, No Pay."—The contract of "no cure, no pay" is probably one which is not very frequently entered into by the most reputable class of the medical profession, although there is, at least, no legal reason why it should reflect any suspicion of discredit upon the physician who is a party to it. When a physician agrees to such an arrangement, and there is no specific price fixed as the compensation for performing a cure, the physician will be entitled to the reasonable and usual sum for performing such services. But before he is entitled to any compensation whatever he is bound to show that he fulfilled his agreement and effected a cure. Where a physician undertook the treatment of a patient upon the plan under consideration, and soon afterward, fearing that the patient was financially irresponsible, represented to the patient's son the propriety of securing the payment by his own written obligation, whereupon the son gave the doctor a memorandum reading as follows: "I hereby agree that I will be holden to Dr. J. S. for the payment of his bill for medicine and attendance upon my father and his wife"—while this agreement of the son was positive in form, it was subsequent in time to the original agreement of the physician and doctor, the basis of which was "no cure, no pay," and was therefore collateral to it, and the physician was not permitted to collect upon the

written agreement without first showing that he had effected a cure.* When a patient enters into an agreement with a physician to be treated upon the basis of "no cure, no pay," he is bound by such agreement to submit to all reasonable treatment prescribed for such a time as may be reasonably calculated necessary to effect the cure. Should the patient refuse to do this, thus rendering it impossible for the physician to complete the cure and reap the benefit of his skill and labor, he is entitled, upon showing such facts, to receive compensation without performing any further services. The amount of compensation to which he would be entitled would depend upon the terms of the contract. If the contract fixed a specific amount as the price of successful treatment, he would be entitled to receive that amount at once; but if the contract was silent as to the amount of compensation, he would be entitled to a reasonable and usual fee for the services already rendered. The patient might, however, in the latter case, for the purpose of proving the services to be without value, introduce evidence to show that the treatment prescribed was not calculated to produce beneficial results, and that the medicine used was worthless and possessed no efficacy in producing the results desired; and for the purpose of proving this the physician may be required to testify as to the ingredients of the medicine used, even though it be a secret preparation of his own.†

A Tennessee case of some years ago, based upon a contract of the character in consideration, was tried, which somewhat amusingly illustrates the prohibition of a certain class of laymen to avoid the payment of a professional bill whenever possible.

In this case a physician contracted with an habitual drunkard to cure him of his unfortunate affliction in consideration of the payment of five hundred dollars.

The treatment seems to have been successful to such an extent that the patient, after using the medicine prescribed, quit his habits of intoxication, and told his friends that he had lost his appetite for ardent spirits, but that he thought he could again acquire his appetite for spirits by beginning with cider or wine. He continued sober for about nine months and then returned to his habits of intoxication. How he acquired the appetite again is not shown.

The question of whether or not drunkenness is a disease that can be cured by medical skill was interposed; the jury was instructed that if the physician was entitled to recover they must find it so to be, and that the physician had not only suppressed or suspended the appetite for a season during the operation of the medicine, but had so far removed it that it would not return unless the patient indulged in such a manner as to a temperate man brings on the propensity. Upon this instruction the jury rendered a verdict for the patient, and the physician promptly appealed.

The supreme court theorized to some extent upon the nature of drunkenness, and concluded that it was a disease produced by the indulgence of a habit, and that if the disease or disposition to drink were destroyed, its return by renewed indulgence proved a disregard of that sense of moral principle which a rational being would be expected to exercise. Applying these theories, the court said: "To admit that after being so placed (the disposition to drink being destroyed) he might return, is to admit that by his own voluntary act he

could defeat the physician of his promised reward; and it would hence follow that, by taking advantage of his own wrong, the physician would have the twofold mortification of losing his fee and seeing his skill mocked at. Therefore it should have been left to the jury to say whether, if the propensity had been destroyed, the patient returned to his habits of drunkenness with the dishonest purpose of evading the contract." The judgment of the trial court was reversed and the case sent back for a new trial upon the lines indicated in the opinion.*

Relevant to the question in consideration is a case which was decided in South Carolina in 1829 and which was never officially reported, but is preserved in the manuscript of the court. In that case a physician undertook to cure a child of a chronic disease with the understanding that he would not charge more than five dollars if not successful. The parent, believing that the child was cured, promised to pay him one hundred dollars, but it afterward appeared that the disease was not cured, but only suspended. The court refused to hold the parent to his agreement to pay one hundred dollars made under his mistaken belief, but remitted the physician to his original agreement.†

Intent that Services shall be Gratuitous; Effect.—Whether or not the intent of the physician at the time he renders services to a patient that such services shall be gratuitous will defeat his right to compensation is a question upon which there is some conflict. The supreme court of North Carolina lays down the rule that if such services "were intended to be, and were accepted as a gift or act of benevolence," then the physician is not entitled to compensation; but if the patient did not understand that such services were intended as gratuitous, and accept them as such, the physician is entitled to compensation, even though he originally intended to make no charge.‡ On the other hand, the court of appeals of Missouri holds that if the physician rendered his services intending them to be gratuitous, he could not subsequently change his mind and collect for them, even though the patient did not know when the services were rendered that they were intended to be gratuitous.§

A careful and critical examination of the reasoning upon which these two decisions are based leads to the opinion that the North Carolina decision is not well founded, and that the Missouri court expresses the true doctrine.

The North Carolina court subjects the transaction to the same test as that required to demonstrate the validity of an ordinary contract—viz.: that there shall be a meeting or concurrence of minds of the parties, and that there shall be a mutual understanding which is agreed to by both. These undoubtedly are necessary elements to the validity of a contract, but, as a matter of fact, the transaction in consideration is not a contract, but a gift, and is accordingly to be governed by the law relating to gifts.

The essential elements of a gift are that the donor or giver shall actually or symbolically deliver the property which is the subject of gift to the donee with the intention that it becomes the donee's without the payment of any consideration. In this case the physician represents
